EXPERIMENT STATION RECORD.

Vol. XVI. September, 1904. No. 1.

Hon. Joseph H. Brigham, whose death occurred suddenly June 29, was the third person to occupy the position of Assistant Secretary of this Department since it was raised to the first rank. In point of service his term was longer than that of either of his predecessors, extending over seven years, which marked a period of the greatest development in the history of the Department.

Colonel Brigham had been for many years a National figure in agriculture, and prominently identified with many of the more important movements for agricultural advancement. He early attained prominence in the Grange, being twice elected to the position of master of the Ohio State Grange, and he served for nine years as master of the National Grange. The latter office gave him a position of wide influence and made him the representative of that great organization in the agricultural matters of the day.

His connection with the experiment station movement, and especially with the Ohio Station, was one of which he was justly proud. During his term in the State senate in 1882 he introduced and secured the passage of an act establishing a State experiment station, and appropriating $3,000 a year for its maintenance. From the first he was quite closely identified with the organization and development of that station, for he was called upon by the governor to suggest the members of the board of control, and as the founder of the station his counsel was sought on important points. At that time there were barely a half dozen stations in existence in the whole country, and there were few people who appreciated the value of an experiment station or realized what it should be.

Upon the reorganization of the station under the Hatch Act in 1888 he was appointed a member of the board of control, which position he held until 1895. It was partly through his efforts that funds were secured for moving the station to its present location, and he lent his aid in obtaining from the State the liberal appropriations for maintenance and for buildings which have enabled it to grow to its present proportions.

It was during Colonel Brigham's incumbency as master of the National Grange that that organization became a strong advocate of the experiment stations, and threw the weight of its influence in support of the Hatch Act, then pending in Congress. On that occasion he headed a legislative committee of the National Grange which was in constant consultation and cooperation with an agricultural college committee, whose efforts were being directed toward the passage of the experiment station bill. The two things which Colonel Brigham's committee stood for especially were the guarding of the expenditures for original investigation and the State control of the details of the work.

A few years later, when the second Morrill Act was under consideration, he again appeared as chairman of a legislative committee of the Grange to promote the interests of agricultural instruction. His committee at first contended that the new appropriation should be assigned entirely to instruction in agriculture, and for a time withheld its support of the measure in maintaining this contention. Later a compromise was effected in the wording of the bill, and the clause restricting the application of the money to instruction in agriculture and the mechanic arts was written in a conference with Colonel Brigham and his committee, which brought the support of the National Grange.

Throughout his life he remained a stanch friend and supporter of the experiment stations of the country, in the making of which he had played a no small part; and their success and advancement to a position of great national importance was a source of pride and gratification to him.

Colonel Brigham was born December 12, 1838, and hence was in his sixty-sixth year at the time of his death. His military title was won in service during the civil war, for which he enlisted in 1861. He served throughout the war and was mustered out of service as colonel of the Sixty-ninth Ohio Volunteer Infantry. After the war he settled in Fulton County, Ohio, where he engaged in farming. He held various offices under the people of his State and county, serving three terms as sheriff of Fulton County, one term in the State senate, for six years as a member of the Ohio State Board of Agriculture, during one year of which he was president of that body. He also served upon the board of trustees of the Ohio State University and as president of the Ohio State board of managers of the penitentiary. In March, 1897, he was appointed by President McKinley to be Assistant Secretary of Agriculture.

During his term of service in the latter office, in addition to his other duties, he was called upon to give much attention to the exhibits prepared by this Department for exposition purposes, and was selected as the Department representative on the Government board for the

Omaha, Buffalo, Charleston, and St. Louis expositions. In each case he was chairman of the Government board, a position of much responsibility and involving the administration of large funds. The success not only of the Department's exhibits, but of the Government exhibit as a whole at these expositions, was due in no small measure to his efficient administration.

The resolutions passed by the chiefs of the bureaus and divisions of the Department at the time of his death are a fitting tribute to his career and to the esteem in which he was held:

"During a service of over seven years as Assistant Secretary, Colonel Brigham, by his qualities of heart and head, deserved and gained the confidence of all with whom he had official relations. In addition, he won the personal regard of all who knew him. The lasting achievements of his busy life, especially his services to agriculture, have won for his name an enduring renown, no less marked than the love and affection which follow him to the grave."

In a recent address delivered by Prof. T. C. Chamberlin, of the University of Chicago, a strong plea was made for the importance of research, both from the standpoint of pure science and its influence upon the progress of learning, and also from that of utilitarian ends. Much of what was said has a direct bearing upon agricultural education and research, and examples from the work of the experiment stations were cited to enforce the speaker's deductions.

The title of the address was The State University and Research,[a] and the occasion of its delivery was the semicentennial jubilee of the University of Wisconsin. Professor Chamberlin laid down the broad proposition that "the fundamental promotion of education lies in an increase of the intellectual possessions of a people, and in the mental activities and attitudes that grow out of the getting, the testing, and the using of these possessions. . . . True ideas work incessantly and unswervingly toward a destined end, while the thousand little waves of merely personal influence cross one another's paths and work one another's destruction. Determinate truth is radioactive, and sends forth a constant stream of penetrating, illuminating emanations, to which only the most leaden intellect is opaque. The discoverers of great truths and the authors of great ideas are the great educators."

He maintained that the education of the individual does not necessarily secure real educational advancement, for if we convey to the rising generation only such ideas as have been inherited, the summit-level of education is not raised. "There is only a Chinese dead-level of ancestral propagation;" and, it may be added, this represented to a considerable extent the condition of agricultural education up to within quite recent times. Some progress was made by voluntary research

[a] Science, Aug. 5, 1904, p. 161.

and by the accretions of common experience, but the fundamental basis of progress was very largely lacking.

To secure laudable progress in the fundamental condition of education, Professor Chamberlin held that systematic provision for scientific research is requisite, and he used the term in a broad sense to include rigorous investigation in any field. "To give this research its best adaptations to the needs of a people, it should be systematically controlled in the lines most tributary to these needs. To make the results available to all who will use them, suitable means for dissemination are requisite. Inevitably the highest intellectual training will grow out of this, for such training is both the prerequisite and the outcome of the struggle to find truth and to test it. Out of this training will come the best possible development of intellectual capacity, of right attitude toward truth, and of considerate action controlled by the scientific spirit."

The change which has taken place in Wisconsin in the attitude toward agricultural questions, as a result of the research and extension work which has been carried on, was cited by the speaker in illustration of the application and far-reaching importance of this phase of education. He said: "It was my privilege to compare the agricultural conventions of this State at two periods separated by a decade, within which the experiment station became a potent influence. The dominant intellectual and moral attitude of the earlier period was distinctly disputatious and dogmatic. Opinions and floating notions played the part that should have been reserved for demonstrations. Interpretations were loose and close analysis rare. In the second period the dominant attitude was that of a scientific conference. Opinions were replaced by demonstrations or by tentative hypotheses. Conviction was sought by the presentation of determinate facts, gathered by experiment and laborious observation, carefully analyzed, and cautiously interpreted. The whole was characterized by a notable approach to the methods of approved scientific procedure. The intellectual and moral contrast of the two periods was one of the most pronounced expressions of advance in the higher education in a great mass of people in the midst of practical life which it has ever been my privilege to witness."

This is a very strong statement and a high tribute to the intellectual and moral uplift growing out of this work—a phase of the result which has seldom been fully appreciated; but the counterpart of the changed condition described in Wisconsin can be found in many other States in the Union to-day, and it is after all of far deeper significance than the more tangible material results.

As bearing upon the relative importance of education for the individual and investigation for the masses, Professor Chamberlin expressed his conviction that while it is a legitimate function of the

State to train boys to be farmers, it is "a much higher and truer function to develop the science of agriculture, to increase the intellectual activity of every farmer, to improve the agricultural art on every farm, and by such improved art to furnish better and safer food to every citizen."

Thus, without disparaging or underrating the value of educating the individual, systematic investigation, which extends the sum of human knowledge along useful lines and disseminates the results so as to make them available to all who will use them, is given a fundamental significance and a place of paramount importance in the general scheme of education.

The thesis is not a new one in science, but it is given a new force by its application to research in agriculture. Few lines could be found which furnish more tangible or convincing evidence of the value of investigation; and the plan of organization under which it has been carried on, coupled with the prompt dissemination of information through bulletins, the farmers' institutes, and other agencies, has been singularly suited to popularize it and give it wide influence.

Investigation has preceded and made possible the new agricultural education, as well as created the demand for it; and while the needs of the people engaged in the art were being studied systematically, and the masses enlightened by bringing the results to their doors, a science of agriculture was being gradually built up by the classification of existing knowledge and the contribution of much that is new. The movement has reached a position where it is attracting the attention of men of science in other lines, and incidentally it has done much to popularize scientific research as a whole and to give confidence in its utility. It is interesting that Professor Chamberlin, with his wide familiarity with research in various branches of science, should have drawn the principal illustration in his argument for research from agriculture; and seldom, it may be noted, has the case for agricultural research been presented more forcefully.

The bulletin on the Agricultural Experiment Stations in Foreign Countries, issued by this Office over two years ago, has been thoroughly revised, and the revision is now in press. The original edition was regarded quite largely as preliminary and intended to serve as a basis for a more complete collection of data. Clippings from it were sent to the directors of the stations and agricultural officials abroad for revision, and in this way most of the data have been verified and supplemented.

As compared with the original bulletin, which listed about 720 experiment stations and similar institutions, this bulletin contains accounts of 798 such institutions arranged in alphabetical order by countries and

cities. Among these, however, are included many institutions which for lack of further information are mentioned in the bulletin by title only, and a quite large number of experimental fields, laboratories, and other enterprises which in this country would not be called stations. Briefly stated, the list includes the various agencies of different kinds and grades for experiment and investigation in agriculture and for the protection and information of farmers. Purely as a matter of convenience, these agencies may be referred to collectively as "stations." As far as possible an attempt has been made to give an idea of the systems in the different countries, and this is followed by a description of the individual stations, their origin, personnel, equipment, revenue, and lines of work.

The revised bulletin demonstrates not only the world-wide extent of the station movement at the present time, but also the substantial growth of the movement during the past two years. Nearly every civilized country of the globe now has its system of institutions for research in agriculture. The most notable exception in Europe is Greece, where, so far as can be learned, there are no stations or similar agencies in operation. In Asia there are a goodly number of stations, located in Russia, Japan, and British India. The Chinese Empire represents a large area which is entirely without stations, and the same condition applies to Turkey, Persia, Afghanistan, and Beloochistan. Africa has quite a large number of stations in the English, French, and German colonies, and several of these are of quite recent origin. There are no stations as yet in Mexico or in Central America except in British Honduras, where a botanical garden is located; and of the South American countries no trace has been obtained of any stations in Bolivia, Colombia, Ecuador, Patagonia, Peru, Uruguay, or Venezuela. Australia and New Zealand have a large number of stations of various kinds, which are actively studying the practical problems suggested by the agriculture of those countries.

The largest number of separate agencies for investigation and experiment in agriculture is found in Russia, in spite of the fact that the movement is comparatively recent there. That country has 115 such establishments and three experimental forests. Many of them are small demonstration fields, established for the purpose of instructing the peasants or of introducing new agricultural industries; others serve as the centers for the production and distribution of improved varieties of seeds and plants, and some are conducted as institutions for research. There are a number of stations for special crops, such as tobacco, sugar beets, silk, cotton, olives, tea, wines, and other products.

In Germany there are listed 87 stations; in France, 74; in Japan, 58; in Austria, 40; in Australia, 35; in Great Britain, 32; in Sweden, 26; in Italy, 25; in Hungary, 22; in Belgium, 16; in Norway, 12; in Switzerland, 11; in Denmark, 10, and in the Netherlands, 7.

A comparison of foreign and American experiment stations makes it apparent that the latter represent a distinct class of institutions, which are the product of their environment. The exact prototypes or counterparts of the American stations are not found in any other country, either in scope, organization and management, or in relation to the farming community and the promotion of agriculture in general. The American station is an adaptation of the European station to the conditions and requirements of this country, and thus presents many unique features.

Taken as a whole, the foreign experiment stations are working in the main independently of one another, there being very little cooperation between the stations of any country or with the central department of agriculture. Such cooperation, which is becoming more extensive in this country each year, may be regarded as one of the characteristic features of the American system.

Attention is called to abstracts given elsewhere (pp. 15–17), describing the utilization of strongly condensed light at right angles to the plane of the microscope. The mechanism of the microscope employed does not differ from those in common use, the only difference being in the sidewise illumination, so focussed as to render the smallest particles visible by their reflecting the light thrown upon them.

The early experiments with this new microscope indicated that it was adapted to use only with liquids, and studies of glycogen, proteids, urine, etc., of great exactness were reported. Recently[a] it has been found to be adapted to studying living organisms, and especially bacteria. It is claimed that with the focal illumination, micro-organisms one-fourth of a micromillimeter in size can be readily distinguished in form, without any preliminary cultivation, staining or other process.

Of course only objects having a different refractive index from that of the medium in which they are suspended can be viewed with this new form of instrument, but with it it seems possible to open up an entirely new field of investigations in physiological chemistry, bacteriology, and related branches.

---

[a] British Med. Jour., 1904, No. 2275, Epit., p. 20.

NEW LIVE STOCK BUILDING AT THE MINNESOTA COLLEGE OF AGRICULTURE.

A building, to be used in connection with the instruction in live stock at the Minnesota School and College of Agriculture, is now in process of construction and will be completed during the fall. The building will serve as headquarters for the live stock department of the station, as well as the college, but is designed principally for the instruction in live stock judging and other branches of animal husbandry.

It is quite unique for a building of this sort, and includes a number of features not usually found in the live stock pavilion or the barn. It is in fact a combination of the live stock pavilion, with recitation rooms and offices, and the stable. The stables accommodate only a

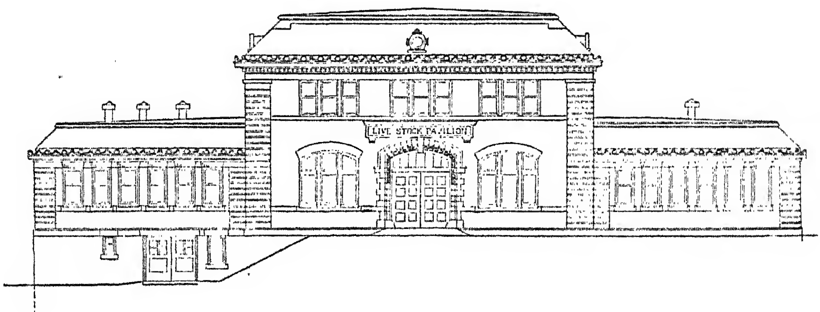

FIG. 1.—North elevation, live stock building, Minnesota College of Agriculture.

limited number of animals and are intended for temporary use, to house the animals while they are being used for instruction purposes. Stock for this purpose is frequently borrowed in order to obtain suitable specimens for illustration, and such animals will be stabled in the barn forming a part of this building while they are at the college grounds. Stock belonging to the college will also be more conveniently housed in this building during the period when it is being used.

The new building will be of brick, with blue limestone foundation and Indiana buff Bedford stone trimmings, and will have a slate roof. It will have a frontage of 136 feet, with a depth of 76 feet in the main part. As shown by the front elevation (fig. 1), it presents the appearance of a central part with wings on either side.

The central portion of the building is two stories high. The first floor (fig. 2) is occupied by an arena extending across the entire front, with class rooms at either end, which can be cut off by sliding doors. The arena proper is provided with a tan bark floor 25 by 104 feet in extent, making it possible to study the gait of a horse without going out of the building. The central part has an amphitheater at the back, seating 225 persons. The two class rooms in the wings are each 36½ by 54 feet, and will accommodate about 150 students each, the

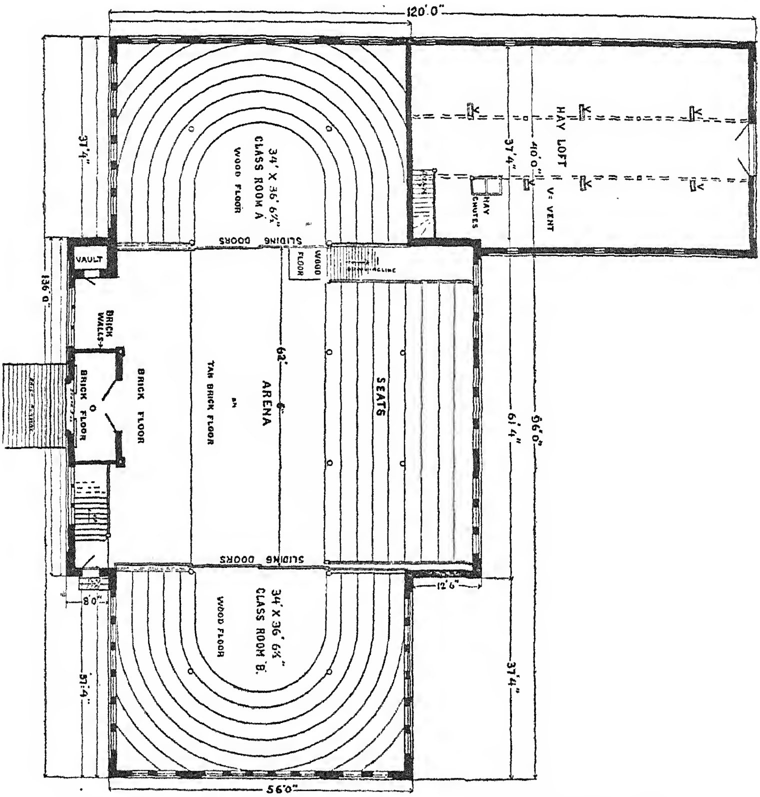

FIG. 2.—First-floor plan, live stock building, Minnesota College of Agriculture.

seats being arranged in semicircular form. All can be thrown together into one large audience room for demonstrations or meetings.

The animals will be brought up to the arena from the stables below over inclines built at an easy grade. Between the tan bark floor and the front of the building will be an area covered with a brick floor, which can be used for instruction in harnessing and hitching up teams, grooming horses, etc.

The second floor of the building (fig. 3) will contain two offices for the department of animal husbandry, a workroom, a museum, and a class room for animal feeding. The workroom will be used for the study of pedigrees, the keeping of feeding records, and for microscopic work. It will be 22 by 28 feet, while the museum and class room will each be 30 by 39 feet in size. On this floor will also be located a dark room, toilet, and a vault for the storage of records and other valuable books.

In the left or east wing are located the stables for the live stock, in a basement and subbasement. The land slopes away from the front

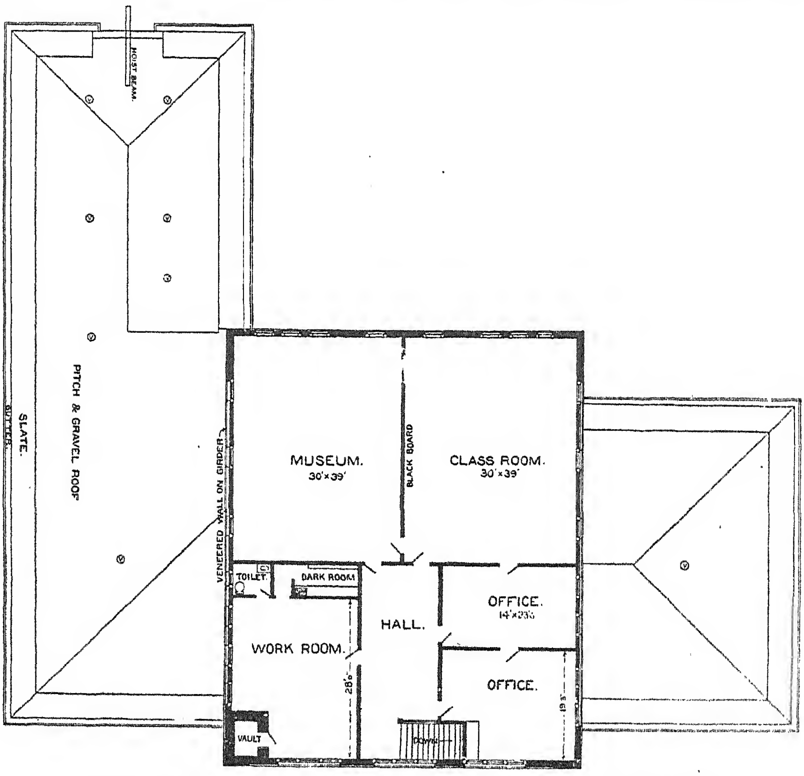

FIG. 3.—Second-floor plan, live stock building, Minnesota College of Agriculture.

in such a way as to make both the basement and the subbasement almost entirely above ground. The subbasement will be used for cattle, and the floor above for horses. This wing runs back something over 50 feet beyond the main part, so that on the basement floor (horse barn) it has a depth of 120 feet from front to back, and a width of 40 feet.

The subbasement, or cattle barn (fig. 4), will have a cement floor and be provided with iron stable fittings. It will contain a number of box stalls, and a root cellar, which will extend into the side hill; and

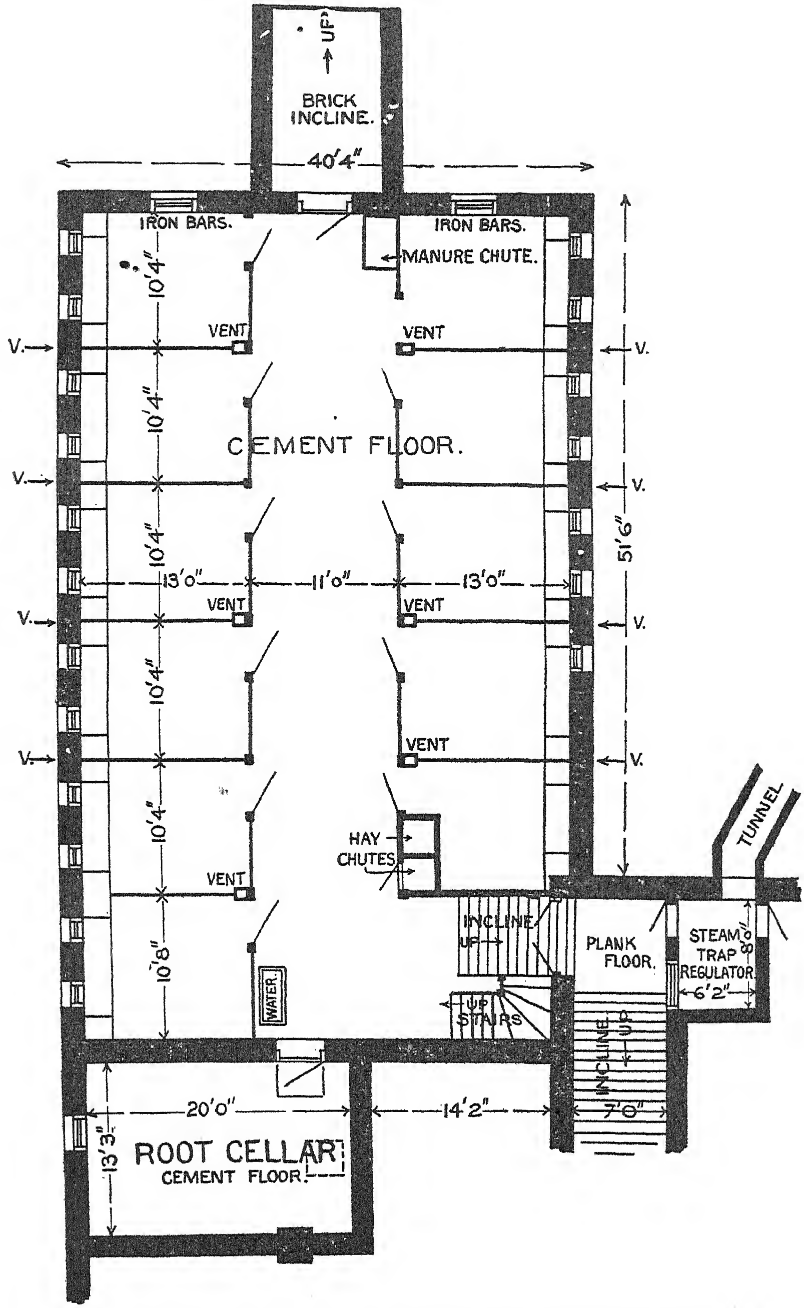

FIG. 4.—Subbasement (cattle barn), live stock building, Minnesota College of Agriculture.

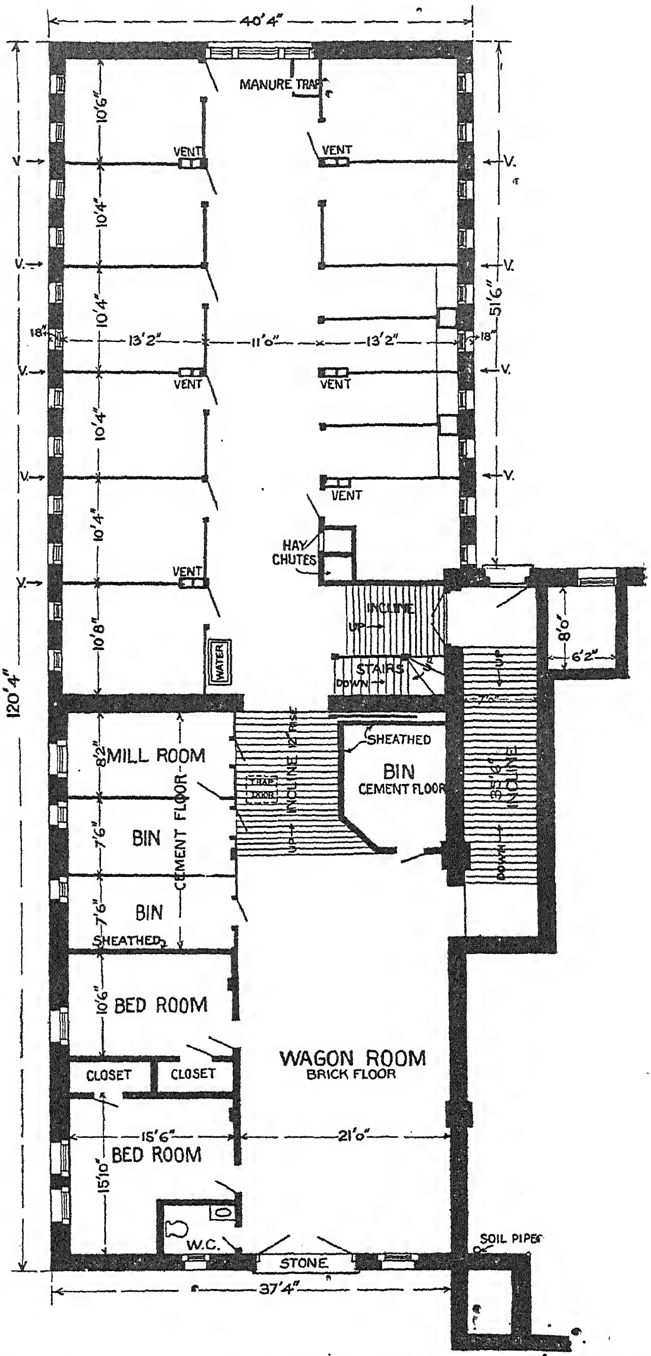

FIG. 5.—Basement (horse barn) live stock building, Minnesota College of Agriculture.

will be provided with hay chutes, a manure chute, and a ventilation system. The tunnel furnishing the building with heat from the central heating plant will enter the building through the subbasement.

The horse barn (fig. 5), located on the floor above, will also be provided with box stalls, and in the front part will contain a large wagon room. On this floor will also be located the bins for grain, two rooms for attendants, and a toilet. The hay loft will be in the attic above the portion of the wing used for stables. The finish in the stables will be in the rough brick; the bedrooms will be plastered and finished in pine, as will also the offices.

The building is being erected out of a State appropriation made by the last session of the legislature and now available. It will cost, with equipment, about $33,000 to $35,000. It will be heated from the central heating plant of the college, and lighted throughout by electricity. It is centrally located, convenient to the cattle stables and the hog and sheep barns, and adjacent to the building erected a few years ago for slaughtering, cutting up, and curing meats.

RECENT WORK IN AGRICULTURAL SCIENCE.

CHEMISTRY.

Comparison of methods for the estimation of soil acidity, F. P. VEITCH (*Jour. Amer. Chem. Soc., 26 (1904), No. 6, pp. 637–662*).—Comparative studies of the sodium chlorid method devised by Hopkins, Pettit, and Knox (E. S. R., 14, p. 111) and the limewater method devised by the author (E. S. R., 14, p. 418) are reported. From the results obtained the author concludes that in the sodium chlorid method "there is no setting free of appreciable quantities of hydrochloric acid, and that there is practically no reaction between the organic matter and the salt solution, whereby difficultly soluble organic acids are dissolved, but that the acidity of the filtrate (or that acidity which is greater than would be given by water under the same conditions) is due to the solution of alumina or some other acid-salt yielding base. It appears that the hydrated neutral silicates or aluminates are quite strongly attacked by the salt solution, resulting in the replacement of aluminum by sodium, or a breaking up of the compound, and the consequent formation of an acid solution of aluminum chlorid, the titration of which, with alkali, constitutes the apparent acidity as determined by this method."

He further concludes that the method can not be relied on for the determination of the total apparent acidity of a soil, or to show the acidity injurious to sensitive crops. "A soil limed in accordance with the results of the sodium chlorid method is never alkaline unless indeed the lime requirement by this method is as great as the lime requirement by the limewater method."

It is plain that the limewater method "shows the maximum lime requirements of soils—that is, it shows the amount of lime required under the most favorable conditions of distribution to make them alkaline in reaction," and it is believed to be "the wisest practice to apply lime in sufficient quantities to render the cultivated soil slightly alkaline in reaction, and consequently to use a method which will indicate this quantity."

The limewater method as modified and improved is as follows: "To determine the reaction of a soil: About 10 gm. of soil are treated with 100 cc. of distilled water in a Jena flask and allowed to stand over night. Fifty cubic centimeters of the supernatant liquid are carefully drawn off and boiled with a few drops of phenolphthalein in a covered Jena beaker until the appearance of the pink color or to a volume of about 5 cc. with no development of color. The pink color shows the soil to be alkaline, while no color shows it to be acid or neutral.

"To determine the degree of acidity: To three portions of soil, each consisting of as many grams as the standard limewater contains milligrams of lime (CaO) per cubic centimeter, add 50 to 60 cc. of distilled water and different amounts of standard limewater. For example, to the first add 10 cc., to the second 20 cc., and to the third 30 cc. of limewater. Dry down at once on the steam bath, transfer to stoppered Jena flasks with 100 cc. of distilled water, allow to stand over night, with occasional shaking, draw off 50 cc., place in a Jena beaker, add a few drops of phenolphthalein solution, and boil until the appearance of the pink color; or, in

case no color is developed, to a volume of about 5 cc. Then, with two portions of treated soils, one of which has been rendered alkaline by the limewater and the other of which is still acid, as guides, prepare three fresh portions of 10 gm. each and add limewater as before, except that the amount added to a dish differs from that added to another by 1 or 2 cc. Dry, take up with 100 cc. of water, allow to stand, draw off, and treat exactly as before. The smallest amount of limewater which gives the characteristic pink color is taken as the acidity equivalent of the soil. Each cubic centimeter of standard limewater is equivalent to an acidity of 0.01 per cent expressed as calcium oxid.

"It is essential that the distilled water used be free from alkalis and acid."

Notes on rapid soil analysis, V. Edwards (*Chem. News, 89 (1904), No. 2316, pp. 183, 184*).—Rapid methods of determining water, phosphoric acid, iron and alumina, lime, potash, and nitrogen are briefly described, and the significance of these various determinations with reference to the use of fertilizers is briefly discussed.

On the determination of phosphoric acid as magnesium pyrophosphate, K. K. Järvinen (*Ztschr. Analyt. Chem., 43 (1904), No. 5, pp. 279–282*).—The author claims that dimagnesium-ammonium phosphate is precipitated and accurate results are thus assured when precipitation is effected as follows: Make the phosphoric acid solution feebly alkaline with ammonia and pour the solution slowly with constant stirring into a perfectly neutral solution of a mixture of magnesium chlorid and ammonium chlorid (102 gm. of the former and 53 gm. of the latter per liter), using about 10 cc. of the solution to each 0.1 gm. of phosphoric acid. The precipitate is crystalline and forms slowly and should carry down with it all free ammonia. Otherwise trimagnesium-ammonium phosphate is formed and the results are too high.

The volumetric determination of potash in the form of double hyposulphite of potassium and bismuth, W. Küster and M. Grüters (*Ztschr. Anorgan. Chem., 36 (1903), pp. 323–331; abs. in Bul. Soc. Chim. Paris, 3. ser., 32 (1904), No. 11, p. 701*).—This is an account of tests of Carnot's method, which is condemned as unreliable.

The determination of nitrogen, L. Débourdeaux (*Bul. Soc. Chim. Paris, 3. ser., 31 (1904), No. 10, pp. 578–580*).—A method is described which it is claimed converts the nitrogen of the following groups of nitrogenous substances into ammonia without mixture of amins: Oxidation compounds of nitrogen, hydroxylamin, nitrogen derivatives of which the nitrogen nucleus contains a phenol group, nitriles, cyanids and double cyanids, cyanates and sulphocyanates, amids and imids in which the nitrogen is not further replaced by a carbon radical, and amins with an acid radical.

The determination is made in a modified Schloesing apparatus of glass as follows: Distill the substance nearly to dryness with 50 gm. of crystallized potassium hyposulphite and 200 cc. of a solution of potassium monosulphid. The latter solution is obtained by saturating a given volume of potash solution, 36° B., with hydrogen sulphid and mixing this with an equal volume of untreated solution. Distill a second time to remove the last traces of ammonia with 25 cc. of potash solution and 250 cc. of water, continuing the distillation until about 150 cc. of distillate has been obtained. The ammonia is determined by titration in the usual manner.

Estimation of nitrites in waters, J. Desfourniaux and L. Robin (*Ann. Chim. Analyt., 9 (1904), pp. 68, 69; abs. in Jour. Chem. Soc. [London], 86 (1904), No. 499, II, p. 367*).—Desfourniaux describes a method based on the liberation of nitrous acid by salicylic acid, in the presence of potassium iodid, and titration of the iodin thus set free. Robin calls attention to his own process, published in 1898, which is practically the same as that of Desfourniaux, acetic acid being used instead of salicylic acid.

The rendering visible of ultramicroscopic particles and their measurement, with especial reference to glass colored with gold, H. Siedentopf and R. Zsig-

MONDY (*Ann. Phys.*, *4. ser.*, *10* (*1903*), *No. 1*, *pp. 1–39*, *figs. 13*).—A method of so lighting objects that those ordinarily invisible under the microscope are rendered visible is described, which is similar in principle to the commonly observed fact that a beam of sunlight in a darkened room renders moats visible.

Light was collected and allowed to strike on the material to be examined at right angles to the line of vision through the microscope. It was found that materials were rendered visible which were in size somewhere between molecular dimensions and the length of a light wave. The minute particles rendered visible had in general a brilliant appearance. The accuracy of the method, its theoretical limitations—that is, the size of the smallest particles which can theoretically be rendered visible—as well as related topics, are discussed and results of a number of experiments with glass colored with gold are reported.

The author points out that the method is capable of application to the examination of colloid substances and similar bodies, and there is no theoretical reason why large complex molecules such as occur with proteids, potato starch, etc., should not be rendered visible.

Ultramicroscopic investigations, MUCH, RÖMER, and SIEBERT (*Ztschr. Diätet. u. Phys. Ther.*, *8* (*1904*), *Nos. 1*, *pp. 19–27*; *2*, *pp. 94–96*).—Using the method and apparatus devised by Siedentopf and Zsigmondy (see above), the authors studied especially the proteid bodies in a number of substances, including horse serum, milk, milk serum, mucin solution, etc.

It was found that when the method was applied to proteid solutions glittering moving particles were observed, which varied in number with the concentration of the solution. These particles were regarded as the protein molecules or molecular groups. The authors devised a method of studying the proteid solutions quantitatively, which depended on diluting the solution to such an extent that only three or four of the glittering particles were observed in the field of vision. The amount of dilution is called the "ultra value." This varied in substances examined from 250 with Marburg nutrient bouillon to 800,000 with milk serum.

A number of samples of urine were examined, and it was found that the method was especially satisfactory for the detection of albumen, and in the authors' opinion is as valuable for the quantitative determination of albumen as is the polarization apparatus for the determination of sugar.

Some of the experiments reported had to do with the products of digestion. It was found that when 0.5 gm. of globulin from horse-blood serum was mixed with 0.5 gm. pepsin and 0.2 gm. hydrochloric acid, and diluted to 100 cc., that the ultra value was 100,000. After standing for half an hour in the incubating closet the ultra value was 100, and after one hour and a half, 25. When milk was digested with pepsin and hydrochloric acid no diminution in the number of particles was noticeable. This was also the case when digested with pancreatin, but if the pancreatin digestion followed that with pepsin and hydrochloric acid the number of particles diminished.

Twenty cubic centimeters of fat-free milk diluted with distilled water to 100 cc. had an ultra value of 750,000, and showed large particles and particles which were smaller and less glittering. Treated with 0.1 gm. pepsin and 0.4 gm. of 25 per cent hydrochloric acid, this quantity of fat-free milk had an ultra value of 500,000 after standing in the incubating closet 2 hours, and an ultra value of 750,000 after standing 24 hours. This remarkable increase in the number of visible particles was confirmed by control experiments. After standing 62 hours the value decreased to 250,000, and none of the large light particles were observed.

Tests were also reported with whey (lacto serum), which the authors consider of especial interest on account of the bactericidal properties. The conclusion was reached that the bactericidal and agglutinating properties go hand in hand with the number of particles rendered visible by the "ultra apparatus." In these tests and

others which were made with horse-blood serum the solutions were treated with an electric current, and the anode and kathode serum and that between the two electric poles was studied. The electric current modified the liquid; horse serum from the anode having a much more marked bactericidal action than untreated serum. In one test the ultra value of untreated serum was 200,000, that of the anode serum 7,000,000, and that of kathode serum 80,000. Differences in the appearance of the serum particles visible with the ultra apparatus are described.

The article contains a brief discussion of molecular energy, with special reference to the kind of investigations reported.

Ultramicroscopic studies of solutions of albumins and carbohydrates with a new optical method for the estimation of albumin in albuminuria, E. Raehlmann (*München. Med. Wchnschr., 50 (1903), No. 48, pp. 2089, 2090*).—Using the method described above, the author studied a number of solutions of proteids and carbohydrates. The method renders visible the proteids in solution even when the individual particles are only 0.000005 mm. in size. These proteid particles appear like specks of light and are in motion. The number of visible particles diminishes with dilution. The application of the recorded data to the study of pathological urine is pointed out.

The carbohydrates examined included dextrin, gum arabic, grape sugar, milk sugar, and glycogen. The results obtained with all these bodies were similar to those with proteids, i. e., extremely minute particles were rendered visible. In the case of the different carbohydrates the appearance of the particles was similar, larger and smaller particles being noted in every case, most of which polarized light. The particles were in motion. The relation, if any, between the number, size, appearance, etc., of the particles and their chemical constitution is a subject for further investigation.

Diastase, when examined by the ultramicroscopic method, showed particles which were similar to those of the other carbohydrates, yet presented some individual characteristics. The glycogen particles were visible in a dilution of 1 to 3,000,000, and were in size equal to about 0.00006 mm., or 0.1 of a wave length. They had a characteristic gray-white color and differed little in size. In moderately dilute solutions the distances between the glycogen particles were about equal and the particles moved with a vibratory motion. In a solution twice as dilute the distance between the particles was twice as great and the energy of the motion seemed correspondingly diminished. At the greatest dilution studied the motion was only minimum. When a drop of diastase was added to the glycogen solution the particles changed instantly in appearance, being replaced by a much smaller number of large and small particles.

Ultramicroscopic investigations, Raehlmann (*Berlin. Klin. Wchnschr., 1904, Feb. 22; abs. in British Med. Jour., 1904, No. 2275, Epit., p. 20*).—Methods of experimenting with Siedentopf's microscope (E. S. R., 16, p. 15) are described. According to the author this instrument may be used for the study of living micro-organisms as well as chemical bodies. It must be remembered that the refraction of light affects only those parts of the particle or micro-organism examined which fall directly in the line of light, and only substances which have a different refraction from the medium in which they are suspended can be seen. The author describes various forms of putrefactive bacteria which he has been able to study by the methods pointed out. He has also observed the effect of bactericidal and antiseptic substances and of electric currents on micro-organisms.

The distribution of nitrogen in the proteid molecule, T. Gümbel (*Beitr. Chem. Physiol. u. Pathol., 5 (1904), p. 297; abs. in Zentbl. Physiol., 18 (1904), No. 4, pp. 93, 94*).—A critical discussion based on analytical data.

Concerning the nitrogenous compounds in ungerminated seeds, E. Schulze and N. Castoro (*Ztschr. Physiol. Chem., 41 (1904), No. 5, pp. 455–473*).—Yellow and white lupines, sunflower seed, wheat germ, and peanut germ were studied. According to the author, arginin, tyrosin, and asparagin are among the nitrogenous compounds in unsprouted seeds which are concerned in the proteid cleavage in

plants. In 2 of the seeds (yellow lupine and peanut germ) vernin was identified. A study of this body led to the conclusion that it contains a carbohydrate group and is to be regarded as a glucosid.

The nature of the principal phosphorus compound in wheat bran, A. J. PATTEN and E. B. HART (*New York State Sta. Bul. 250, pp. 169–176*).—Previous investigations (E. S. R., 15, p. 496) having shown that 86.5 per cent of the phosphorus of wheat bran is, on an average, soluble in water, the nature of this phosphorus was investigated.

The wheat bran was extracted with 0.2 per cent hydrochloric acid for several hours, with frequent stirring, and filtered. Practically the entire amount of phosphorus in the filtrate was in the form of a phospho-organic acid present in the bran as magnesium-calcium-potassium salt.

The free acid was prepared from the salt present in the wheat bran and its properties studied. When heated with concentrated mineral acids, it broke up quantitatively into inosite and phosphoric acid.

"The free acid corresponds to the formula $C_2H_8P_2O_9$, and is probably identical with Posternak's anhydro-oxymethylene diphosphoric acid. The alkali salts of this acid are freely soluble in water. The calcium and copper salts are slightly soluble, while the barium and strontium salts are but sparingly so. The acid and its salts seem to be of wide distribution in the vegetable kingdom, having already been isolated from the seeds of red fir, peas, beans, pumpkin, red and yellow lupine, also from the potato and other tubers and bulbs."

Cleavage products of elastin, E. ABDERHALDEN and A. SCHITTENHELM (*Ztschr. Physiol. Chem., 41 (1904), No. 4, pp. 293–298*).—Quantitative determinations of the products obtained by the hydrolysis of elastin are reported. The following were found: Glycocoll, leucin, alanin, phenylalanin, α-pyrrolidin-carbonic acid, glutaminic acid, and aminovaleric acid.

Notes on lupeol, E. SCHULZE (*Ztschr. Physiol. Chem., 41 (1904), No. 5, pp. 474–476*).—Data regarding lupeol, a body obtained from yellow lupines, are reported.

On the detection of cocoanut oil in lard, F. MORRSCHÖCK (*Ztschr. Untersuch. Nahr. u. Genussmtl., 7 (1904), No. 10, pp. 586, 587*).—Determinations were made of the refractometer, iodin absorption, and saponification numbers of 3 samples of lard; the alcohol extract of these samples, and of the residue left from the alcohol extract.

In extracting with alcohol the fat was treated with either 2 or 3 volumes of alcohol and heated to 45 or 60° C. on a water bath. From 1.65 to 2.38 per cent of the fat was dissolved in the alcohol. Mixtures were also made of lard and 5 or 10 per cent of cocoanut oil and examined in the same manner. The alcohol extract of the pure samples showed a refractometer number of 2.7 to 3.4, a saponification number of 192.2 to 194.1, and an iodin number of 69.13 to 70.11, while the mixture of lard and 5 per cent of cocoanut oil showed a refractometer number of −0.1, a saponification number of 206.6, and an iodin number of 56.93, and the mixture of lard and 10 per cent of cocoanut oil a refractometer number of −3.4, a saponification number of 221.6, and an iodin number of 46.56.

The author concludes that this method is of great value in determining the presence of cocoanut oil in lard.

On the detection of butter adulteration by means of the phytosterin acetate test, M. SIEGFELD (*Ztschr. Untersuch. Nahr. u. Genussmtl., 7 (1904), No. 10, pp. 577–585*).—The author prepared cholesterin and cholesterin acetate from gallstones, lard, whale oil, and butter fat; and phytosterin and phytosterin acetate from rape-seed oil, cotton-seed oil, sesame oil, and cocoanut oil, and determined the melting points of the different preparations in order to ascertain the accuracy of the Bömer method for the detection of butter adulteration with vegetable oils and fats.

The melting point of the different preparations of cholesterin acetate varied from 113.6 to 115.4° C. The melting point of the different preparations of phytosterin

acetate varied from 128.3 to 136.5°. Acetates were also prepared from different fat mixtures and determinations made of the melting point. The results of the author's investigations confirm the work of Bömer, that the difference in the melting points of the acetates afford a reliable means of determining the presence of vegetable fats in animal fats.

A contribution to the investigation of cheese, J. B. NAGELVOORT (*Pharm. Weekbl., 41 (1904), No. 2-4, pp. 289-295; abs. in Chem. Centbl., 1904, I, No. 17, p. 1234*).—A method is given for the determination of moisture and fat in cheese.

New bases derived from sugars, ROUX (*Ann. Chim. et Phys., 8. ser., 1 (1904), Jan., pp. 72-144; Feb., pp. 160-185*).—In the investigations here reported over 40 salts and derivatives are described as new products.

Apparatus and method used in saponifying compounded oils, P. H. CONRADSON (*Jour. Amer. Chem. Soc., 26 (1904), No. 6, pp. 672-675, fig. 1*).

An extraction apparatus with mercury seal, O. VON CZADEK (*Ztschr. Landw. Versuchsw. Oesterr., 7 (1904), No. 5, pp. 443, 444, fig. 1*).—A combination of Soxhlet extractor, flask, and condenser is illustrated and briefly described.

A new burette cock, F. PILZ (*Ztschr. Landw. Versuchsw. Oesterr., 7 (1904), No. 5, pp. 441, 442, figs. 2*).—A modification of the Mohr device.

Miscellaneous chemical investigations (*Wisconsin Sta. Rpt. 1903, pp. 314-317*).—This is a summary of the following articles previously published by the station: Analyses of Wisconsin Soils, by F. W. Woll (E. S. R., 9, p. 536); The Marls of Wisconsin, by F. W. Woll (E. S. R., 8, p. 208; 9, p. 543); On the Yield and Composition of Sow's Milk, by W. A. Henry and F. W. Woll (E. S. R., 10, p. 782); The Composition of Sow's Milk, by F. W. Woll (E. S. R., 12, p. 84); A Rapid Method for the Estimation of Salt in Butter, by A. Vivian (E. S. R., 13, p. 16); Tables for Use in Kjeldahl Method for Determination of Nitrogen, by A. Vivian (E. S. R., 13, p. 16); An Apparatus Facilitating the Analysis of Sugar Beets, by R. H. Shaw (E. S. R., 13, p. 916), and Miscellaneous Chemical Work, by R. H. Shaw (E. S. R., 13, p. 916).

Proceedings of the twentieth annual convention of the Association of Official Agricultural Chemists held at Washington, D. C., November 19, 20, and 21, 1903, edited by H. W. WILEY (*U. S. Dept. Agr., Bureau of Chemistry Bul. 81, pp. 252*).—This is the official account of the proceedings of the convention, of which a summary was given in E. S. R., 15, p. 427. The bulletin also contains brief biographical sketches of the late Ervin E. Ewell and Norman Robinson, and also the constitution of the association.

BOTANY.

An investigation into the effects of water and aqueous solutions of some of the common inorganic substances on foliage leaves, J. B. DANDENO (*Trans. Canad. Inst., 7 (1902), II, No. 14, pp. 237-350, pls. 2, figs. 16*).—This paper gives the result of a series of investigations conducted to ascertain the effect of certain solutions of inorganic salts on foliage leaves, the effect of nutrient salts on the growth of young leaves developing from the bud, and also the statement that distilled water remaining on the leaf of the plant for some time becomes alkaline.

After giving a historical résumé of the subject the author describes his experiments in detail. It was found that wilted leaves, whether detached from the plant or not, will absorb water if immersed or if the water be applied to the surface in the form of a fine spray. Special parts of the leaves of certain plants seem to be particularly adapted to this absorption, as is shown by the surface of the epidermal cells over the veins and in other regions. Guttation drops and dew drops contain substances in solution which are generally resorbed by the plant. Carbonates present as incrustations may serve to store up, in the presence of moisture, carbon dioxid at night and utilize the same as the bicarbonate is reduced to the carbonate in the daytime.

Distilled water was found to become alkaline very generally if allowed to remain on the leaves of plants for a considerable time. Certain plants which are adapted to growth in moist climates may be made to take in all the food necessary for growth through the leaves. Distilled water used as a spray may for a time act as a stimulant to plant growth. This action may probably be due to the fact that it draws from the plant the surplus alkaline salts which, if too abundant in the cells, might become harmful. Rain water probably acts as a stimulus in the same way.

Solutions applied to the surface of detached leaves, or leaves still upon the plant, are generally absorbed, as shown by the increased content of ash. When so applied the solutions often stimulate a portion of the leaf to abnormal development, producing a ring upon the leaf by the peculiar action of the evaporating drop. When applied to the cut ends of the petioles of leaves, solutions generally kill the tissue at the termination of the tracheids, either by withdrawing the water from the intercellular spaces or by chemical action upon the walls of the cells or on the cell contents. The first determinable reaction after the death of the tissues is alkaline, even though the tissues themselves may be killed by an acid.

In the experiments reported it was found that substances in solution frequently ascend through the blade of the leaf at a rate which varies with the length of the different veins of the leaf. The lithium test, frequently used to determine the ascent of the liquid through plants, is often a source of error, as the water ascends faster than the salt in solution.

Experiments with woody branches of willows showed that the food required for the early spring growth of this shrub was water, and that nutrient solutions at this stage proved harmful. Water and other solutions applied to the twigs showed that they were not absorbed through the bark, but the indications showed that the absorption takes place through the buds.

Experiments with sea water showed that the effect produced upon the atmosphere results in an accumulation of rust upon iron greater than that produced upon the atmosphere under the influence of pure water; and it is concluded from this that a similar physiological process accompanying the chemical process may result with plants growing in the vicinity of the sea.

On account of the economic importance of the subject, the author devotes a considerable portion of the paper to the physiological effect of some of the constituents of Bordeaux mixture when used as a fungicide, and some of the causes of natural and artificial spotting of tobacco. The paper concludes with a bibliography of some of the more important work dealing with this subject.

The physiological action of iodin and fluorin compounds on agricultural plants, S. Suzuki and K. Aso (*Bul. Col. Agr., Tokyo Imp. Univ., 5 (1903), No. 4, pp. 473–479, pl. 1*).—The authors having determined that potassium iodid in exceedingly high dilution exerted a stimulating effect on various plants, conducted experiments with this and sodium fluorid on a number of economic plants. With oats and radishes the stimulating effect of these chemicals was quite evident and the increased crop was made at a correspondingly very small cost.

In commenting upon the effect of potassium iodid the authors state that the substitution of the crude ash of seaweeds would probably be the most economical way of securing the iodid. Attention is called to the fact that farmers along the coast of Japan apply seaweeds as a green manure with very great success, and it is probable that this success is due not only to the small quantities of potash, nitrogen, and phosphoric acid, but also to the small quantity of iodin present.

The physiological effect of rubidium chlorid on plants, O. Loew (*Bul. Col. Agr., Tokyo Imp. Univ., 5 (1903), No. 4, pp. 461–465, pl. 1*).—Pot experiments with Chinese cabbage, barley, and spinach are reported in which the effect of rubidium chlorid was tested. Where the chemical was added in amounts not to exceed 10 mg. per 50 kg. of soil a stimulating effect was noted, the treated plants being larger and the fresh and dry weights greater in nearly every instance. When applied at the

rate of 50 mg. per 50 kg. of soil the stimulating effect on the cabbage was apparent, but was not as great as when smaller quantities were used.

The influence of a certain ratio between lime and magnesia on the growth of the mulberry tree, K. Aso (*Bul. Col. Agr., Tokyo Imp. Univ., 5 (1903), No. 4, pp. 495–499, pl. 1*).—Experiments are reported which seem to indicate that a normal development of the mulberry tree depends to a considerable extent on the ratio of lime and magnesia offered the roots. Pot experiments are reported in which the relation between the lime and magnesia varied from 1:3 to from 4:1; and the results obtained seemed to indicate that the best ratio of lime to magnesia for mulberry trees lies between 2 and 3 parts lime to 1 of magnesia. An excess of magnesia over lime retards growth; the leaves of the plants are small, but the symptoms of the dwarfing disease are not noticeable.

The influence of different ratios between lime and magnesia upon the development of Phaseolus, G. Daikuhara (*Bul. Col. Agr., Tokyo Imp. Univ., 5 (1903), No. 4, pp. 501–503*).—Experiments are reported in which varying quantities of lime and magnesia were added to pots in which beans were grown, and based upon the vigor of growth, height of stems, and size of leaves the best ratio, at least before the fruiting stage of this plant, was 2 parts of lime to 1 of magnesia.

The effect of boric acid in high dilution on plants, M. Nakamura (*Bul. Col. Agr., Tokyo Imp. Univ., 5 (1903), No. 4, pp. 509–512, pl. 1*).—It having been shown by various authors that soils in certain districts contain small quantities of borates and that the plants grown on such soils contain some boric acid, the author has reported on the effect of borax on cultures of barley. It was found that 50 mg. of borax per kilogram of soil acted injuriously on the development of the barley, and that even when used in as small a quantity as 10 mg. per kilogram of soil it had an injurious effect. When used at the rate of 1 mg. per kilogram of soil borax exerted a stimulating action on peas, and 5 mg. had a similar effect on spinach.

Can potassium ferrocyanid exert any stimulant action in the soil on plant growth? S. Suzuki (*Bul. Col. Agr., Tokyo Imp. Univ., 5 (1903), No. 4, pp. 517, 518*).—It having been shown that potassium ferrocyanid in dilute solution is decidedly injurious to plants in water cultures, the author has investigated the presence of this chemical in soil as shown by the effect produced on barley.

To 1 series of pots containing 10 kg. of soil 0.1 gm. potassium ferrocyanid was added and to another 1 gm. Barley was sown in each pot and after a few weeks a decided difference was noticed in favor of the pot receiving 1 gm. potassium ferrocyanid. The favorable action in this case is believed to have been due to the decomposition of the potassium ferrocyanid by bacteria in the soil. For the present it is undecided whether the potassium ferrocyanid acts directly as a stimulant or whether its decomposition products are available as a source of nutrients for the plant.

Influence of the carbon dioxid given off by the soils on plant growth, E. Demoussy (*Compt. Rend. Acad. Sci. Paris, 138 (1904), pp. 291–293; abs. in Chem. Centbl., 1904, I, No. 11, p. 832*).—Experiments with lettuce plants indicate that growth was promoted by conditions favoring the evolution of carbon dioxid by the soil.

The ascent of water in trees, G. Macloskie (*Science, n. ser., 20 (1904), No. 499, pp. 116–118, figs. 2*).—The author discusses some recent investigations on the ascent of water in trees, and offers suggestions based upon well-known laws of physics that, in his opinion, aid in the explanation of this phenomenon.

The theory of functional capacity and its significance in agriculture, L. Daniel (*Trav. Sci. Univ. Rennes, 1 (1902), No. 3, pp. 415–481, figs. 10; 2 (1903), No. 2, pp. 73–272, pls. 20, figs. 81*).—An elaborate review, with many citations from the author's experimental work, and final broad generalizations are here given on the relationship existing between the absorption of plants and the assimilation and transpiration of the crude material absorbed. Plants which grow naturally are first

considered and then the abnormalities which are brought about by such horticultural practices as grafting.

By functional capacity is meant the processes involved in the absorption and utilization by the plant of crude materials. If the functional capacity of absorption or the total absorption from external surroundings be represented by *ca*, and the functional capacity of consumption or the total consumption at the points where the sap is used up be represented by *cv*, then in a plant which is in complete equilibrium as regards its general nutrition we have cv=ca and $\frac{cv}{ca}=1$. If, however, aerial consumption is greater than the usual subterranean absorption, then we have the formula $\frac{cv}{ca}>1$. This corresponds to growth in a dry or poor soil. When absorption is greater than consumption, corresponding to growth in moist or rich soils, the formula becomes $\frac{cv}{ca}<1$.

Conditions similar to these are sometimes brought about by grafting. The cicatrization of the grafted plants and the intercalated tissue between stock and scion interfere with the conduction of sap, modifying it both in quantity and quality. These modifications of the scion are equivalent to growth in a drier, poorer medium than the normal. In grafting it is also necessary to keep in mind the relative functional capacities of the two grafted plants. For if, for example, the functional capacity of consumption is greater in the scion plant than in the stock plant this condition becomes exaggerated by the scar of cicatrization when the two plants are grafted, and the graft either fails to take or makes a poor growth, corresponding to that in the poor, dry soil. The chance for making a successful graft in such a case is increased if the development of adventitious roots from the scion is encouraged, so that assimilation may correspond more closely to a normal absorption of the scion. Again, the same scion may be inserted on 2 stocks or additional attention given to manuring and watering the stock plant.

The discussion is accompanied by numerous drawings, showing the modification of the wood and the character of scars caused by grafting together plants of different functional capacities. The papers have been published in book form under the title La Théorie des Capacités Fonctionnelles et ses Conséquences en Agriculture. Rennes, France: Fr. Simon, 1902.

The influence of climate and soil on the transmitting power of seeds, W. W. TRACY (*Science, n. ser., 19 (1904), No. 488, pp. 738–740*).—An account is given of the practices followed by seedsmen with relation to the influence of soil and climate on the transmitting power of seeds. These practices are the results of long-continued experience rather than the result of scientific study.

In regard to leguminous plants, such as peas and beans, the author reports that on very rich soils or those which have been recently fertilized, a greater deviation from type will be noted than when the plants are developed on poor soils. A stock grown on a white-clay soil will ripen uniformly, while if planted on a rich mucky soil it will develop a large proportion of plants which are departures from the type. If seed of plants that have departed from the type are planted in soils favorable for the development of the true type they will produce nearly as great a proportion of typical plants as those grown from the seed produced from plants that did not show any departure.

In the case of garden beans there is apparently a tendency to produce thick fleshy pods, slow to mature, when grown on rich moist soils, while on warm, sandy soil the pods are less fleshy and quicker matured. These characteristics seem to be carried by the seed and are cumulative in character. So far as the author's observations go there does not seem to be any influence of climate shown by the seed of leguminous plants.

In the experiments with sweet corn no influence of soil has been noticed, but the author believes that the climatic conditions have a marked influence, and that the difference between stock grown in the East and West is a result of climatic rather than of soil conditions.

In the case of cucurbitaceous plants no variation due either to climate or soil was ever noticed.

In conclusion the author says: "Plants of different natural orders differ in the degree to which influences of soil and climate are transmitted through the seed."

Mutation in plants, D. T. MacDougal (*Amer. Nat., 37 (1903), No. 443, pp. 737–770, figs. 10*).—In this paper, which is No. 48 of the Contributions from the New York Botanical Garden, the author gives a review of the work of De Vries on mutation in plants, describing the various forms which have been developed from *Œnothera lamarckiana* in the botanical garden at Amsterdam. The result of the writer's investigations of a number of plants grown from seeds of these mutation forms are described at considerable length, particular attention being paid to *Œ. nanella* and *Œ. rubrinervis*. Both of these are clearly separable from the parent and from each other by physiological and taxonomic standards. These mutation derivatives are found to be constant in their character, with no connecting or intergrading forms, and their specific characters are borne out by their behavior when hybridized with one another.

The latent life of plants, R. A. Robertson (*Trans. and Proc. Bot. Soc. Edinburgh, 22 (1902), pt. 2, pp. 178–191*).—A discussion is given of the effect of gravity, light and darkness, temperature, contact, injuries, chemicals, etc., on plant activity.

Further experiments in plant breeding at the experimental farms, W. Saunders (*Proc. and Trans. Roy. Soc. Canada, 2. ser., 8 (1902), IV, pp. 115–123, figs. 6*).—A record is given of plant breeding experiments carried on by the author, in which the results obtained with cross-bred wheats, barleys, oats, peas, apples, and gooseberries are given.

Methods in plant physiology, H. S. Reed (*Reprinted from Jour. Appl. Micros. and Lab. Methods, 6 (1903), Nos. 4–10, pp. 2267–2270, 2317–2320, 2386, 2387, 2428–2430, 2464–2466, 2515–2517, 2569, 2570, figs. 11*).—The author describes a number of simple experiments in geotropism, heliotropism, and other plant motions.

Experiments on peas in water culture, J. Golding (*Centbl. Bakt. u. Par., 2. Abt., 11 (1903), No. 1, pp. 1–7, figs. 4*).—An account is given of water cultures designed to investigate the process of the nitrogen fixation in the root tubercles of peas, and especially to confirm the results of Nobbe and Hiltner (E. S. R., 12, p. 113).

The peas were grown in nitrogen-free water cultures, receiving an otherwise complete fertilizer. They were inoculated with water extract from crushed pea tubercles so that plenty of organisms could be introduced to their roots. Duplicate cultures were maintained and different series were provided. In one series the roots were as far as possible covered with water; in the second air was excluded by covering the surface of the water with oil; in the third the tubercles were exposed by raising them out of the liquid, while in others the tubercles were covered and either air or oxygen passed through the culture media.

The growth of the different series is shown by figures and described, the author commenting upon the results. It was found that raising the roots out of the water was an injurious process. The oil on the surface of the water prevented nitrogen assimilation, and as there was also no access of oxygen the plants suffered.

The results of the experiment seem to confirm those of Nobbe and Hiltner. Nitrogen assimilation took place only where the root tubercles were covered with water, but even in this case the growth was much less than where the cultures were supplied with combined nitrogen. In sand cultures the author has found the presence of healthy tubercles on the roots to produce growth equal to or better than plants

given a complete fertilizer, but this was not the case under the conditions of the water cultures.

An ecological comparison of some typical swamp areas, S. M. COULTER (*Missouri Bot. Garden Rpt., 15 (1904), pp. 39–72, pls. 24, maps 3*).—The author presents a study of a number of swamp areas in northern Michigan, in Illinois, and in Arkansas, the intention being to group together the available data preliminary to field work on the part of the writer and others. The different regions are described, the characteristic vegetation, distribution of species, etc., being shown.

Some aspects of desert vegetation, D. T. MACDOUGAL (*Plant World, 6 (1903), No. 11, pp. 249–257, pls. 5, figs. 5*).—This article, which is No. 46 of the Contributions from the New York Botanical Garden, describes some of the more striking features of the prominent types of vegetation occurring in the arid regions of this country and calls attention to phases of their life history which need further investigation.

Some rare moor builders, R. TOLF (*Svenska Mosskulturför. Tidskr., 17 (1903), No. 5, pp. 322–324*).—The 3 species of plants described in this paper are but seldom met with in the flora of Swedish moors: *Grimmia hypnoides, Stereodon imponens,* and *Cetraria nivalis*.—F. W. WOLL.

Aberrant veil remnants in some edible agarics, W. TRELEASE (*Missouri Bot. Garden Rpt., 15 (1904), pp. 83–85, pls. 10*).—Attention is called to the fact that occasionally some species of mushrooms which are known to be edible retain some remnants of veil which would, among inexperienced individuals, result in their being considered as poisonous species.

Concerning the toxicology of Amanita muscaria, E. HARMSEN (*Arch. Exper. Path. u. Pharmakol., 50 (1903), p. 361; abs. in Hyg. Rundschau, 14 (1904), No. 10, pp. 486, 487*).

METEOROLOGY—CLIMATOLOGY.

The climate of the Philippines, J. ALGUÉ (*U. S. Dept. Com. and Labor, Census of the Philippine Islands Bul. 2, 1903, pp. 103, pls. 27, maps 2*).—This is a detailed account based on all available observations. It includes, besides notes on physiography of the islands, soils, vegetation, etc., summaries and discussions relating to temperature, aqueous vapor, and atmospheric movements, including surface winds, higher air currents, and extraordinary air currents (baguios, or cyclones, and thunderstorms).

"While the temperature, as indicated by the thermometer at the sea level, is practically the same throughout the entire area of the archipelago, the topographical features of the different islands, and the longitudinal direction of the mountains and hills with reference to the prevailing winds, have a marked effect on the amount of rainfall as well as on the duration of the rainy season. Therefore, while in provinces like Rizal, Batangas, Tayabas, and Bulacan there is a rainy season and a dry season, whose limits can be fairly well defined, there are other provinces, like Albay, Samar, and Surigao, where it usually rains at short intervals throughout the entire year, and where, as a consequence, the climate is more especially adapted to the cultivation of certain important crops than in other provinces.

"The prevalence of typhoons, or, as they are called in the Philippines, 'baguios,' during the summer months, frequently with disastrous results to the shipping, has always been the cause of much apprehension to the owners of vessels and to shippers, but with the establishment of the meteorological department of the Manila observatory in 1865, and the systematic study of these storms, which was commenced by Father Faura, S. J., at that time, and carried on in later years by Father Algué, S. J., the laws governing their origin and movement have been so fully established that their progress, duration, and intensity can now be predicted with great accuracy, and timely notice of their approach be given wherever there is a telegraph station. . . .

"It is sufficient to say here that all important ports in the Philippine Islands now have weather observers who are in telegraphic communication with the central weather bureau in Manila, to which daily reports of the state of the thermometer, barometer, and the direction and force of the wind are telegraphed.

"The cable communication recently established with Guam, not far from which typhoons originating in the Pacific are supposed to form, will add greatly to the accuracy of the predictions and will admit of far earlier and more timely notice of the phenomena which precede and attend their formation and movement."

Climatic charts of the United States (*U. S. Dept. Agr., Weather Bureau Doc. 301, charts 26*).—These include 6 Washington daily weather maps 16½ by 22½ in., for February 1 to 6, 1903, inclusive, showing the movement of a typical storm, with full explanation of symbols, etc.; 5 charts of normal precipitation, quarterly and annual, for the period from 1871 to 1895, inclusive; 3 charts of normal sunshine, January, July, and annual, for the period from 1871 to 1895, inclusive; 3 charts of normal barometric pressure, reduced to sea level, January, July, and annual, for the period from 1873 to 1899, inclusive; 3 charts of normal temperature of the air at the surface of the earth, January, July, and annual, for the period from 1871 to 1895, inclusive; and 6 charts of temperature, showing the mean maximum and the mean minimum temperatures of the air at the surface of the earth in January and July during the period from 1871 to 1901, inclusive, and the highest and lowest temperatures ever observed at the Weather Bureau stations.

Monthly Weather Review (*Mo. Weather Rev., 32 (1904), Nos. 1, pp. 1–50, figs. 11, charts 12; 2, pp. 51–104, figs. 18, charts 12; 3, pp. 105–158, figs. 9, charts 11*).—In addition to the usual reports on forecasts, warnings, weather, and crop conditions, meteorological tables and charts for the months of January, February, and March, 1904, recent papers bearing on meteorology, etc., these numbers contain the following articles and notes:

No. 1.—Special contributions on Problems of the Atmosphere (illus.), by J. Dewar; Tornado at Moundville, Ala. (illus.), by F. P. Chaffee; Arrangement of Lightning Rods (illus.), by W. S. Franklin; A New Nethoscope, by L. Besson; The Earthquake of January 20, 1904, at Washington, D. C., by C. F. Marvin; Lunar Halo of January 30, 1904, by F. L. Odenbach; Studies on the Circulation of the Atmospheres of the Sun and of the Earth—III.—The Problem of the General Circulation of the Atmosphere of the Earth (illus.), by F. H. Bigelow; and notes on meteorology in Servia, the climate of southwestern Idaho, flow of spring water after first killing frost, an old description of American climates, on lightning rods, forest fires in November, 1819, plant life and rainfall, ocean wave at Honolulu, Hawaii, lowest temperature at Franklinville, N. Y., meteor at Marion, Ind., the peculiarities of California northers, our climatological publications, Weather Bureau men as instructors, hurricane of August 14–15, condition of the ocean, and paths of storm centers.

No. 2.—Special contributions on Disposition of Rainfall in the Basin of the Chagres (illus.), by H. L. Abbot; Solar Halo of February 4, 1904, at Milwaukee, Wis. (illus.), by J. W. Schaffer; A Brief Discussion of Conditions Contributing to Freshets in the James River Watershed (illus.), by E. A. Evans; Studies on the Circulation of the Atmospheres of the Sun and of the Earth—IV.—Values of Certain Meteorological Quantities for the Sun (illus.), by F. H. Bigelow; and the Temperature Element of the Climate of Binghamton, N. Y. (illus.), by W. E. Donaldson; and notes on desirability of complete rainfall records.

No. 3.—Special contributions on The Diminution of the Intensity of Solar Radiation during the Years 1902 and 1903 at Warsaw, Poland, Russia, by L. Gorczynski; Origin of American Cold Waves; Destructive Storms in Kentucky, February 7, 1904 (illus.), by H. B. Hersey; Tornado at Meridian, Ill.; Rain at Freezing Temperatures, by E. D. Emigh; Formation of Clouds over Lake Michigan in Winter, by C. H. Lee; Remarkable Meteors, by F. H. Schofield; Precipitation for Twenty-nine Years at

Dodge City, Kans., by E. D. Emigh; Detailed Cloud Observations in Colorado, by J. B. Willsea; Midwinter Weather Conditions in Western Ontario, by A. G. Seyfert; A West Indian Storm, by J. S. Quin; Remarks on Bigelow's Studies on the Circulation of the Atmosphere, by A. Woeikof; The Vertical Component of the Wind (illus.), by M. Dechevrens; A Study of Some Errors of Kite Meteorographs and Observations on Mountains (illus.), by H. H. Clayton; The Transvaal Observatory, by R. T. A. Innes; Climate of Siberia, Korea, and Manchuria, by E. B. Garriott; The Winter of 1903–4, by W. B. Stockman; and notes on wind effects (illus.), Argentine Republic weather service, seismological work, [meteorological] averages by months or by seasons, a Hawaiian Weather Bureau station, uniformity in methods and standards of instruction in meteorology, weather forecasts by local observers, new astrophysical and meteorological observatories, a new mountain observatory, kite ascensions at Kazan, polarization of the light of the sky, the winter of 1903–4 at Thompson, Windham County, Conn., local storm at Portland, Oreg., bright meteor of September 15, 1902, and hypotheses as to the cause of the aurora borealis.

Report of the Meteorological Council (*Rpt. Meteor. Council [Great Britain], 1903, pp. 180, fig. 1, map 1*).—An account of the work of the council during the year ended March 31, 1903, in the lines of ocean meteorology, weather telegraphy and forecasts, climatology, and miscellaneous investigations is given, with statements regarding publications of the council and its library and finances. Information of a miscellaneous character is given in a series of appendixes. The success of 8.30 p. m. forecasts during 1902–3 was, complete 53 per cent, partial 35 per cent. The averages for the preceding 10 years were, complete 55.7 per cent, partial 27.3 per cent.

Meteorological observations, Moscow, Idaho, 1902, J. E. Bonebright (*Idaho Sta. Rpt. 1903, pp. 18–30*).—Daily and monthly summaries are given of observations on temperature, precipitation, pressure, cloudiness, and wind movement.

Report of the meteorologist, N. Helme (*Rhode Island Sta. Rpt. 1903, pp. 275–291*).—This includes general notes on the weather during the year ended June 30, 1903, and a tabulated record of observations at Kingston on temperature, precipitation, cloudiness, and prevailing winds during each month from July, 1902, to June, 1903, inclusive, with a summary for the year ended June 30, 1903. The latter summary is as follows:

Temperature (degrees F.).—Maximum, 90, July 9, and August 4, 1902; minimum, −12, December 9, 1902; mean, 48.3; highest monthly mean, 67, July, 1902; lowest monthly mean, 27.2, December, 1902; highest daily mean, 77.5, July 9, 1902; lowest daily mean, −2, December 9, 1902. *Precipitation* (inches).—Total (rain and melted snow), 59.27; greatest monthly, 9.19, March, 1903; least monthly, 0.70, May, 1903; greatest in 24 consecutive hours, 2.50, April 15, 1903; snowfall—total 45. *Weather.*—Number of clear days, 138; number of fair days, 96; number of cloudy days, 131; number of days on which there was precipitation of 0.01 in. or more, 103. *Prevailing wind,* west.

Meteorological observations, J. Haltner et al. (*Jahrb. St. Gall. Naturw. Gesell., 1901–2, pp. 621–640*).—Summaries are given of observations on pressure, temperature, relative humidity, cloudiness, precipitation, wind movement, etc., during 1902 at a number of stations in St. Gall.

Meteorological observations, J. S. Part et al. (*Agr. Bul. Straits and Federated Malay States, 3 (1904), No. 4, pp. 147–157*).—Tables give monthly rainfall from 1894 to 1903 in the various districts of Negri Sembilan; daily observations on temperature, rainfall, humidity, and wind movement at Seremban during February, 1904; and abstracts of similar observations during the month of March at Singapore, Penang, Malacca, Perak, Selangor, Negri Sembilan, Pahang, and Muar.

Report on radiation of the international meteorological committee at Southport in 1903, J. Violle (*Ann. Chim. et Phys., 8. ser., 2 (1904), May, pp. 134–*

144).—A review of investigations on methods and apparatus which have been used in isolating and measuring the energy of solar rays.

The movement of temperature and the precession of the equinoxes, J. PÉROCHE (*Rev. Sci.* [*Paris*], *5. ser.*, *1* (*1904*), *No. 19*, *pp. 579–583*).—A discussion of the relation of the alleged change of seasons to the precession of the equinoxes.

The floods of the spring of 1903 in the Mississippi watershed, H. C. FRANKENFIELD (*U. S. Dept. Agr.*, *Weather Bureau Bul. M*, *pp. 63*, *pls. 16*, *figs. 3*, *charts 15*).—This is a detailed account of the causes and history of these floods fully illustrated with maps, charts, reproductions of photographs, etc.

Instructions governing the corn, wheat, cotton, sugar, and rice region service (*U. S. Dept. Agr.*, *Weather Bureau Doc. 304*, *pp. 8*).—The second edition.

WATER—SOILS.

Underground waters of New Jersey. Wells drilled in 1903, G. N. KNAPP (*Rpt. State Geol. New Jersey*, *1903*, *pp. 73–93*, *map 1*, *dgm. 1*).—A brief discussion is given of the physiographic features of the Appalachian, Crystalline Highlands, Piedmont, and Coastal areas of the State and their relation to the artesian water supply. A record is also given of the wells bored during the year.

The water and soil conditions of Grado and the neighboring coast region, A. N. PAPEŽ (*Ztschr. Landw. Versuchsw. Oesterr.*, *7* (*1904*), *No. 3*, *pp. 77–110*).—A number of analyses of waters and soils are reported and discussed with reference to the utilization of the coast sands for agricultural purposes.

Preliminary report on the soils and agricultural conditions of north-central Wisconsin, S. WEIDMAN (*Wisconsin Geol. and Nat. Hist. Survey Bul. 11*, *1903* (*Economic Ser. 7*), *pp. VIII+68*, *pls. 10*).—The area reported on includes Portage, Wood, Clark, Marathon, Taylor, and Lincoln counties, and adjoining portions of Langlade, Price, and Gates, and covers 7,200 square miles. The topics treated are (1) location and general topographic and geologic features, (2) general character and origin of soil and descriptions of the soil formations, and (3) climate and precipitation, history, and agricultural conditions.

"The area is an undulating slope rising gradually from the south and southwest. Its southern border has an elevation of 900 to 1,100 ft. above sea level, and its northern border an elevation of 1,350 to 1,650 ft. The surface is generally plain-like in southern Clark County, in the southern half of Wood, over a large part of southern and central Portage, and throughout a strip of variable width in Marathon along the Wisconsin River as far north as Wausau. A part of central and southwestern Langlade is also a plain. Outside the area of these plains the surface is a rolling country, with gentle slopes along the valleys and broad slopes over the uplands."

The region is well watered. The soils, which are to a large extent the result of glacial action, are classed on the basis of texture in 14 types, which are mapped and described with reference to area, surface features, general character and origin, ground water, forest growth, and crops. They include Wisconsin River sandy soil, Bancroft gravelly sandy loam, Antigo gravelly loam, Amherst sandy loam, Chelsea clay loam, Cary sandy loam, Mentor loamy sand, Kennan clay loam, Harrison sandy gravelly soil, Colby loamy clay, Marathon loam, Mosinee gravelly soil, Ackley gravelly clay, and swamp and marsh soil. "It is believed that the soils of this area contain all the chemical elements necessary for the growth of crops, and that the varying degree of fertility of the different soils is probably due to their texture and the physical conditions surrounding them."

The summary of meteorological observations by the United States Weather Bureau at several places in the area for 1892–1903 shows that the weather conditions are modified appreciably by Lakes Superior and Michigan both as regards temperature and moisture. The temperature is shown to have varied during the period referred

to from −28.2 in January to 99.1° F. in July. The average annual rainfall varied from 27.5 in. at Stevens Point to 33.12 in. at Neillsville. Killing frosts occur occasionally as late as May and June. They do not occur earlier in the fall than in northern Illinois or Iowa.

Note on scale for chemical valuation of soils, V. EDWARDS (*Chem. News, 89 (1904), No. 2317, p. 197*).—The author states that in judging fertility of the soil from a chemical standpoint he "would describe a good soil as containing 0.25 per cent of each of the three essential ingredients, nitrogen, phosphoric acid, and potash; thus, the three added together, 0.75 would equal 100, and from their analysis all soils could be in a manner compared with the 'standard' imaginary one."

Promising methods for the investigation of problems of soil and plant physiology, and some lines of investigation to which they are adapted, F. H. KING (*Proc. Soc. Prom. Agr. Sci., 1904, pp. 171–190*).—The author points out the importance from the standpoint of the relation of soil moisture to crop yield of "a simultaneous study which would reveal quantitatively and qualitatively the character of the solution which the soil moisture represents, both as it exists in the soil under the growing crop and after it has been absorbed and becomes functional in plant growth."

The development of satisfactory rapid methods, mainly volumetric, for this purpose is referred to (see also E. S. R., 15, p. 457) and tests of their reliability in comparison with gravimetric methods in determining the water-soluble salts of type soils and the concentration of plant sap and culture solutions are reported. The results of some preliminary studies by means of the methods on the capillary movement of dissolved salts in mulched and unmulched soils are also reported.

Can plant analysis determine the content of assimilable plant food in soils? M. STAHL-SCHRÖDER (*Jour. Landw., 52 (1904), No. 1–2, pp. 31–92*).—A series of plat experiments made in 1893 and 1894 with oats, on light and heavy soils, with different combinations of fertilizing materials, is reported, with analyses of the grain and roots of the plants from each plat, the object of the experiments being to determine the value of Heinrich's method [a] of root analysis and Atterberg's method of seed analysis as means of determining the assimilable plant food in soils.

The results indicate that the first method is of little or no value and in many cases leads to erroneous conclusions, and that the second method gives results which are not of general application but apply only to the particular climatic and soil conditions of the region in which the experiments are made. The composition of the seed varies considerably with the season and with the character of the soil, but apparently is not appreciably affected by the variety or the time of planting.

The water-soluble plant food of soils, H. SNYDER (*Proc. Soc. Prom. Agr. Sci., 1904, pp. 25–31*).—See E. S. R., 15, p. 543.

Studies on the development and distribution of nitrates and total water-soluble salts in field soils (*Wisconsin Sta. Rpt. 1903, pp. 339–345*).—A summary of investigations during the 10 years ending with 1903. The following articles are included: Soluble Salts in Cultivated Soils, by F. H. King and J. A. Jeffery (E. S. R., 12, p. 28); Soluble Salts in Cultivated Soils, by F. H. King and A. R. Whitson (E. S. R., 13, p. 24); Development and Distribution of Nitrates and Total Soluble Salts in Cultivated Field Soils, by F. H. King and A. R. Whitson (E. S. R., 13, p. 229); Development and Distribution of Nitrates in Cultivated Soils, by F. H. King and A. R. Whitson (E. S. R., 14, p. 231); Influence of the Soil on the Protein Contents of the Crops, by A. R. Whitson, F. J. Wells, and A. Vivian (E. S. R., 14, p. 955).

---

[a] Grundlagen zur Beurteilung der Ackerkrume, Wismar, 1882.

Potash of the soil: Its assimilability and the influence of lime on its circulation, C. SCHREIBER (*La potasse du sol: Son absorbabilité.—Influence de la chaux sur sa mise en circulation. Brussels: Imp. l'Auxiliaire Bibliographique, 1903, pp. 32, figs. 10*).—Pot experiments extending over a number of years (1898–1901) with oats on a variety of soils, with and without potash and other fertilizers, are reported. The comparative results are shown in the following table:

Relative decline in yield of oats with different elements lacking in fertilizers.

Year.	Without nitrogen.	Without phosphoric acid.	Without potash.	Without lime.	Without magnesia.
1898	100	100	100	100	100
1899	71	72	29	87	94
1900	57	52	20	88	103
1901	30	47	11	88	81

This table shows that the assimilable potash of the soil was rapidly exhausted by the oat plants.

The application of potash salts increased the yield of both straw and grain. Other experiments are reported which indicate that lime, or better, gypsum has a marked though limited effect in setting free the potash of the soil.

Studies on the improvement of marsh soils (*Wisconsin Sta. Rpt. 1903, pp. 333–338*).—A summary of investigations during the 10 years ending with 1903. The following articles are included: The Treatment of Swamp or Humus Soil, by F. H. King (E. S. R., 9, p. 536; 10, p. 728); The Treatment of Swamp or Humus Soil, by F. H. King and J. A. Jeffery (E. S. R., 12, pp. 32, 36); The Influence of Potash Salts on Black Marsh Soils, by F. H. King and A. R. Whitson (E. S. R., 13, p. 27); Studies on Black Marsh Soil, by F. H. King and A. R. Whitson (E. S. R., 13, p. 931); Experiments on Black Marsh Soil, by A. R. Whitson (E. S. R., 14, p. 949).

Report on the work of the Swedish Moor Culture Association, 1902 (*Svenska Mosskulturför. Tidskr., 17 (1903), No. 5, pp. 333–347*).—The report describes the activities of the association during the year 1902. These come mainly under two headings, investigations of a chemical or botanical nature and experiments in crop production on moor soils, conducted partly on the experiment farms at Flahult and Jönköping, partly on farms in different parts of the country.—F. W. WOLL.

Soil temperatures for the year 1902, J. E. BONEBRIGHT (*Idaho Sta. Rpt. 1903, pp. 31, 32*).—This is a weekly summary of observations on the temperature of the soil at depths of 1, 3, 6, and 9 in., and 1, 2, 3, 4, 5, and 6 ft.

Observations on soil temperatures during the years 1896-1899 at Mustiala Agricultural and Dairy Institute, T. CANNELIN and L. STENBÄCK (*Landtbr. Styr. Meddel., 1903, No. 44, pp. 99–159*).

Formation of nitrous acid in the air confined in arable soil. Nitrification by chemical processes in the soil, F. SESTINI (*Orosi, 27 (1904), pp. 1–9; abs. in Jour. Chem. Soc. [London], 86 (1904), No. 499, II, p. 363*).—The author finds that the formation of nitrous acid in the soil by the oxidizing action of ferric hydroxid is due to oxidation of ammonia, and not of nitrogen of the air as claimed by Bonnema (E. S. R., 14, p. 850).

The formation of nitric acid and nitrification as a chemical process in cultivated soils, F. SESTINI (*Landw. Vers. Stat., 60 (1904), No. 1–2, pp. 103–112*).—See above.

Recent progress in soil bacteriology, J. BEHRENS (*Mit. Deut. Landw. Gesell., 19 (1904), No. 26, pp. 181–184*).—A brief general summary of investigations.

FERTILIZERS.

Fertilizer trials on Swedish moor soils, 1900–1902, H. VON FEILITZEN (*Svenska Mosskulturför. Tidskr., 17 (1903), No. 6, pp. 396–420, figs. 10; 18 (1904), No. 2, pp. 73–95, figs. 14*).—*Method of applying artificial fertilizers.*—Experiments were conducted during the season of 1902 with Peluschke peas for the purpose of ascertaining the best method of applying artificial fertilizers as to depth of distribution in the ground. The results showed that the phosphoric acid in Thomas phosphate gave a 42 per cent higher yield of green substance when carefully mixed with the soil to a depth of 15 cm. than when the phosphate was simply harrowed in to a depth of 5 cm., which gave the lowest yield. No appreciable difference in yield was obtained with potash salts whether the fertilizers were mixed with a considerable depth of soil or only harrowed in. The artificial fertilizers were in all cases applied in the spring of the experimental season.

On the effect of different nitrogenous fertilizers on moor soils.—The following summary statement shows the average relative effect of different nitrogenous fertilizers on moor soils obtained in experiments which were conducted by the author during the period given. Seven trials were made with oats, 1 with barley, and 2 with spring rye. The amount of nitrogen applied was generally 45 kg. per hectare (40 lbs. per acre), and in some cases 30 kg. (27 lbs. per acre).

Relative effect of nitrogenous fertilizers on moor, sandy, and clayey soils.

Fertilizer.	Moor soil (7 trials).	Sandy soil (2 trials).	Clayey soil (1 trial).
Nitrate of soda	100	100	100
Sulphate of ammonia	93	79	75
Fish guano	71	79	89
Peat-litter poudrette	59	50	57
Barnyard manure	37	22	13

The nitrate produced the highest yields in 8 out of 11 trials, the sulphate produced the highest yields in 3 cases, the poudrette produced least in 1 trial, and the barnyard manure least in 10 trials.

Experiments of the same character with oats and potatoes at Flahult experiment station, 1900–1902, in which the effects of nitrate, sulphate, and fish guano were compared, gave the following average comparative results: Nitrate, 100; sulphate, with oats, 91, with potatoes, 86; fish guano, with oats, 85, with potatoes, 47.

Barnyard manure v. *artificial fertilizers.*—Experiments conducted during 1901–1903 with barnyard manure *v.* artificial fertilizers for oats or pastures on moor soils gave results showing that barnyard manure can not be applied to advantage under these conditions, but should be accompanied with an application of phosphate and potash. On nitrogenous moor soils of the better class the most profitable fertilization was obtained on the plats receiving only phosphate and potash.

On the fertilizer value of ground gabbro and feldspar on moor soils.—The experiments with these materials which are found on the market and sold under the name of "mineral fertilizers" showed that at least for the crops under trial, alsike clover and Peluschke peas, the effect of their application was practically zero.

On the use of different phosphatic fertilizers on moor soils.—Comparisons of superphosphate, Wiborgh phosphate, and Thomas phosphate have been made in experiments conducted under a great variety of conditions and with different crops since 1898. The conclusion was drawn from the results of the earlier series of trials that the citrate-soluble phosphoric acid in Wiborgh and Thomas phosphates has the same fertilizer value when applied on moor soils as the water-soluble and the citrate-soluble acid in superphosphate for the crops on which the fertilizer is applied. The latter experiments gave decided evidence that the action of the soluble phosphoric acid in the 3

phosphatic materials on moor soils may be considered equal, and that the residual effect of the fertilization with Wiborgh and Thomas phosphates was more pronounced than that of superphosphate.

Experiments with different potash salts.—The results of earlier experiments were corroborated, showing that the different potash salts on the market may be considered of equal value for grain crops, legumes, or pastures on moor soils. The potash salt that can be bought at the lowest price per unit of potash is therefore to be preferred, since the cost of freight is of importance in determining the price of the fertilizer in local markets, the 37 per cent potash salt and the muriate being generally preferable. This is especially true in the case of fertilization of potato land. The high-grade salts produced the largest crops of potatoes, and the starch content of the potatoes was 1 to 2 per cent higher in the case of plats to which such salts had been applied than from fertilization with kainit.

On the action of lime and soil amendments on barren moor soils.—Plat experiments were conducted with soil from a piece of moor land which did not normally grow any crops, and which consisted in its upper layer of partially decomposed Eriophorum plants. It is shown that such soils can be made to produce normal crops of oats, peas, etc., through liming, admixture of sand or clay, and proper fertilization with phosphates, potash, and even some nitrogen. Barnyard manure also produced good effects and is of value for the purpose of facilitating the decomposition of the organic matter in the soil. The improvement in the quality and the yields of the crops harvested on plats receiving different treatment was striking.—F. W. WOLL.

Some lessons learned from experiments with fertilizers, W. SAUNDERS (*Proc. Soc. Prom. Agr. Sci., 1904, pp. 105–112*).—A brief general discussion of the fertilizer requirements of plants and a summary account of the experiments with fertilizers made at the experimental farms at Ottawa since 1887.

The so-called statistical method of making field experiments with fertilizers and calculating the results, T. PFEIFFER (*Mitt. Landw. Inst. K. Univ. Breslau, 2 (1904), No. 4, pp. 647–682, fig. 1*).—This is a controversial article replying to one by Dafert (E. S. R., 15, p. 130), which explains the doubtful reliability of field experiments ordinarily conducted by farmers, and the need of greater accuracy in such experiments if they are to yield results of scientific and practical value, reference being made to the author's plan for securing greater interest in this subject by offering a series of premiums (E. S. R., 13, p. 726).

The main portion of the article, however, is devoted to a detailed discussion of the reliability of conclusions based upon averages of the results of a large number of individual experiments—the so-called statistical method advocated by Dafert—the general tenor of this discussion being that more reliable and useful results may be obtained by increasing the accuracy of individual experiments rather than by increasing the number of cooperative experiments as ordinarily made.

Plant food and use of fertilizers, A. L. KNISELY (*Oregon Sta. Bul. 79, pp. 40*).—A popular discussion of this subject, including directions for making fertilizer experiments and preparing mixtures for different crops.

A contribution to the knowledge of metaphosphates, F. WARSCHAUER (*Ztschr. Anorgan. Chem., 36 (1903), pp. 137–200; abs. in Bul. Soc. Chim. Paris, 3. ser., 32 (1904), No. 11, pp. 653–655*).—This article gives a critical historical review of investigations on this subject, and describes the distinctive characteristics of the various modifications of metaphosphoric acid, including monometaphosphates which are uncrystallizable, insoluble salts; trimetaphosphates which are easily crystallizable and soluble, but are not precipitable; tetrametaphosphates which are crystallizable, soluble, and precipitable; and hexametaphosphates which are amorphous compounds, the alkaline salts giving with the salts of the alkaline earths and heavy metals precipitates which are either flocculent or gelatinous. The preparation and chemical behavior of various salts of these acids are discussed.

Investigations on the fertilizing value of dried superphosphates, A. GRÉGOIRE and J. HENDRICK (*Bul. Agr. [Brussels], 20 (1904), No. 2, pp. 185–201, fig. 1*).—Chemical studies and pot experiments with barley to determine the effect of drying superphosphates on their fertilizing value are reported in detail.

The conclusions reached were that the physical changes brought about by the heating were without effect on the fertilizing value of the product; partial dehydration brought about by heating to 165° C. increased the activity of the phosphoric acid to a notable degree; the mixture of soluble calcium salts resulting from heating monocalcium phosphate to 165° C. until it lost 2 molecules of water was as a rule more effective than crystallized monocalcium phosphates; the calcium metaphosphate produced by dehydration of monocalcium phosphate was of no value as a fertilizer; calcium pyrophosphate produced by complete dehydration of bicalcium phosphate is also of no fertilizing value.

A contribution to the study of phosphatic slag, A. GRÉGOIRE and J. HENDRICK (*Bul. Agr. [Brussels], 20 (1904), No. 2, pp. 202–209*).—Ammonium citrate containing per liter 210 gm. citric acid, 43 gm. ammoniacal nitrogen, and 30 gm. of ammonium fluorid dissolved about half as much of the phosphoric acid of Thomas slag as 2 per cent citric acid. Pot experiments with barley indicated that a large part of the phosphoric acid insoluble in the ammonium citrate containing fluorid was readily assimilable by plants.

On the influence of liming on the availability of phosphoric acid in commercial fertilizers, B. SCHULZE (*Fühling's Landw. Ztg., 53 (1904), Nos. 5, pp. 186–188; 6, pp. 216–222; 7, pp. 261–265*).—A series of pot experiments is reported, from which the conclusions are drawn that the phosphoric acid of bone meal produces an effect in soil poor in lime which very closely agrees with that indicated by the solubility in citric acid; liming reduces the effect of water-soluble phosphoric acid least, of citric-acid soluble phosphoric acid more, and of bone phosphoric acid most; the most injurious effect was produced by liming with burnt lime in the spring, the least by applications of calcium carbonate in the fall; the action of the phosphoric acid of bone depends not only upon the form and time of application but also upon the kind of plant, mustard, for example, utilizing it more completely than oats; liming injuriously affects the phosphoric acid of the soil, rendering it less soluble; the acid compounds of the soil are apparently of considerable value in rendering difficultly soluble phosphates available.

On the influence of liming and marling on the yield of vetches, R. ULBRICHT (*Landw. Vers. Stat., 60 (1904), No. 1–2, pp. 135–146, pl. 1*).—Pot experiments during 1897, 1899, and 1903 are reported. The results show that vetches, like serradella and lupines tested in previous experiments, are injuriously affected by large applications of lime or marl, although not as sensitive as the latter and in some cases actually benefited by small applications of lime or marl.

Concerning the function of sodium when used in nitrate of soda, H. J. WHEELER ET AL. (*Rhode Island Sta. Rpt. 1903, pp. 237–267, pl. 1*).—This article reviews the work of other investigators on the function of sodium as a plant nutrient, and summarizes the work of the authors which has been carried on at the Rhode Island Station for a number of years. The objects and results of this work are briefly summarized as follows:

"The experiments were designed to throw light upon the question whether the frequent greater effectiveness of nitrate of soda as compared with sulphate of ammonia, when employed at such rates that each furnishes like amounts of nitrogen, is due to a direct manurial action of the sodium, as claimed by Wagner and Dorsch, or in part to other causes.

"Other experiments at this station with about 200 varieties of plants have shown conclusively that plant growth is very greatly influenced by the chemical reaction of the soil, or by compounds formed as a result of the reaction, a fact which seems

established beyond question. Many tests of soils, where both nitrate of soda and sulphate of ammonia have been used, have shown that they influence greatly the chemical reaction of the soil. The nitric acid of the nitrate of soda is taken up by plants leaving a basic residue, while on the other hand the ammonia of sulphate of ammonia is changed to nitric acid and utilized by plants, and sulphuric acid is left as a residual product.

"Wagner and Dorsch, citing European experiments in support of their contention that nitrate of soda is frequently more efficacious than sulphate of ammonia by virtue of a direct manurial action of sodium, make no mention of a possible influence of the chemical reaction of the soil as affected by these salts. Indeed, they cite the Rothamsted results in support of their conclusions. It was pointed out, however, several years ago by one of us (H. J. W.) that the inefficiency of sulphate of ammonia at Rothamsted as compared with nitrate of soda was probably due to the resultant difference in the reaction of the soil which lime was shown to be capable of overcoming. In fact, recent experiments with lime at Rothamsted have shown that it corrects the condition, thus fully demonstrating the position taken at this station, and furnishing further evidence in support of the conclusion from our own experiments.

"The results secured here are to the effect that the differences in the yields produced by nitrate of soda and sulphate of ammonia are not attributable, at least, more than to a limited extent, and then perhaps only with a few kinds of plants, to a direct manurial action of the sodium, but often chiefly to the difference in the chemical reaction of the soil which is brought about by the two salts.

"The conclusion reached is further supported by the fact that the greater efficiency of nitrate of soda, as compared with sulphate of ammonia in our own experiments, was not apparently by virtue of the capacity of soda to act as a carrier of nitric acid to the plant."

The influence of the depth of application of straw on the yield, C. von Seelhorst and W. Freckmann (*Jour. Landw., 52 (1904), No. 1–2, pp. 163–171, pls. 6*).—Pot experiments with oats grown on loam and sandy soils with and without aeration and different amounts of water to determine the influence on denitrification of applications of straw or strawy manures, aeration, moisture, and the character of the soil are reported. The results show that when nitrate was applied the deeper the application of straw or strawy manure the greater the denitrification. In the case of loam soil without nitrate applications of straw in the upper half of the soil were the more injurious.

Influence of applications of strawy manures on yield when used in connection with lime and sulphuric acid, C. von Seelhorst and W. Freckmann (*Jour. Landw., 52 (1904), No. 1–2, pp. 172–174, pl. 1*).—A brief account is given of pot experiments with mustard, the results of which show that the use of such materials as lime and sulphuric acid, which hasten the decomposition of the strawy manures, lessen their injurious effect on the yield, although they do not entirely overcome it.

The value of straw ash, E. Herrmann, E. Hotter, and J. Stumpf (*Separate from Oesterr. Landw. Wchnbl., 30 (1904), Nos. 6, 8, 12, 13*).—The fertilizing value of this material is discussed.

Nitrifying organisms, E. Boullanger and L. Massol (*Ann. Inst. Pasteur, 18 (1904), pp. 181–196; abs. in Jour. Chem. Soc. [London], 86 (1904), No. 499, II, p. 361*).—Observations on the behavior of nitrifying organisms in the presence of various carbonates, nitrites, and ammonium salts are reported.

The nitrous organism accommodates itself to all ordinary carbonates, but does not attack hydroxylamin hydrochlorid. The nitric organism oxidizes nearly all nitrites in solutions containing 0.5 to 1 gm. per liter. Nitrification took place in a great variety of ammonia salts tested, but in case of ammonium arsenite, iodid, citrate, and

oxalate only in solutions containing 0.5 to 1 gm. per liter. The nitrous organism appeared to have an incubation period of 6 days, the nitric organism of only 2 days.

Ammonium salts hindered the multiplication of nitric organisms, but did not interfere with the action of those already present. The minimum retarding amount of ammonia was found to be about 2 parts per million. It is thought that the amount of ammonia in soils under ordinary conditions is too small to interfere with the multiplication of nitric organisms.

Analyses of fertilizing substances sent on for free examination, C. A. Goessmann (*Massachusetts Sta. Bul. 95, pp. 18*).—Analyses are reported of miscellaneous materials, including wood ashes, cotton-hull ashes, limekiln ashes, sulphate of ammonia, nitrate of soda, cotton-seed meal, muriate of potash, high grade sulphate of potash, acid phosphate, dissolved boneblack, phosphatic slag, Belgian phosphate, tankage, steamed bone, ground bone, dry ground fish, mill refuse, wool dust, cotton-seed droppings, cotton-seed dust, cocoa shells, lime refuse, waste lime, dried dandelion root, compound fertilizers, peat, muck, meadow mud, silt deposit, and soils. Notes are also given on the valuation of fertilizers, and on taking samples for analysis.

Commercial fertilizers, P. Schweitzer (*Missouri Sta. Bul. 63, pp. 22*).—A report on the registration and inspection of fertilizers in Missouri during the year ended December 31, 1903, including the text of the State fertilizer law approved March 14, 1903, the details of analyses, and advice to farmers regarding the purchase and use of fertilizers.

Inspection of fertilizers in 1903, F. W. Morse (*New Hampshire Sta. Bul. 108, pp. 63–71*).—This bulletin contains a brief statement regarding fertilizer inspection during 1903 in cooperation with the State Board of Agriculture, and reports analyses of wood ashes and miscellaneous fertilizing materials. The text of the State fertilizer law and a schedule of trade values of fertilizing constituents for 1903 are given.

Miscellaneous analyses, B. L. Hartwell, A. W. Bosworth, and J. W. Kellogg (*Rhode Island Sta. Rpt. 1903, pp. 233–236*).—Analyses of dried blood, ammonium sulphate, nitrate of soda, tankage, wool waste, horn meal, hoof meal, acid fish, star fish, dissolved bone, dissolved boneblack, double superphosphate, acid phosphate, raw aluminum phosphate, muriate of potash, sulphate of potash, air-slaked lime, dried distillers' grains, timothy hay, Buffalo horse feed, Buffalo poultry feed, Buffalo creamery feed, mixed feed, cotton-seed meal, and precipitate from sewage tanks.

Commercial fertilizers (*Wisconsin Sta. Rpt. 1903, pp. 307–313*).—This is a brief summary of the work of the station on commercial fertilizers during the period from 1896 to 1903. The following articles are included:

Fertilizer experiments, by F. W. Woll (pp. 307–309).—Fertilizer Experiments with Indian Corn on Marsh Soils (E. S. R., 10, p. 729); Fertilizer Experiments with Sugar Beets on Marsh Soils (E. S. R., 12, p. 46).

Analyses and general discussions of fertilizers, by F. W. Woll (pp. 309–313).—The Maintenance of Soil Fertility: Commercial Fertilizers (E. S. R., 8, p. 212; 9, p. 543); Fertilizing Value of Lake Mud (E. S. R., 9, p. 543); Fertilizers for Lawns (E. S. R., 11, p. 528).

A list of articles on fertilizer inspection is also given, with a brief history of fertilizer inspection in the State and analyses of fertilizers inspected during 1903.

Fertilizers licensed for sale in Wisconsin in 1904, F. W. Woll and G. A. Olson (*Wisconsin Sta. Bul. 113, pp. 3–13, 18, 19*).—This is a report of the results of analyses of 18 samples of fertilizers licensed during 1904, with notes on the sources, nature, purchase, valuation, and use of fertilizers, and the text of the State law.

FIELD CROPS.

Cooperative experiments in agriculture, C. A. Zavitz (*Ontario Agr. and Expt. Union Rpt. 1903, pp. 10–29, map 1*).—A discussion of the organization of the work is presented, and the results for 1903 and in some cases the average results for a series

of years are tabulated and noted. The yields of the leading varieties of roots and forage crops are given in the following table:

Results with the leading varieties of root and forage crops in 1902.

Crop.	Number of tests.	Number of varieties tested.	Leading variety.	Yield per acre.
				Tons.
Mangels	12	3	Sutton Mammoth Long Red	43.68
Sugar beets	12	2	New Danish Improved	27.02
Swedish turnips	3	3	Magnum Bonum	26.01
Parsnips and carrots	4	3	Pearce Imp. Half Long White Carrot	27.70
Fodder corn	2	3	Mastodon Dent	18.20
Millet	4	3	Japanese Barnyard	3.51
Sorghum	1	3	Early Amber Sugar Cane	18.25
Grass peas and vetches	4	3	Common Vetches	9.47
Rape	2	2	Dwarf Bonanza	18.69

In 1903 corn planted in hills gave but a slightly larger yield than corn planted in drills. In the average of 4 years the results show a difference of 1 ton of total crop and one-fifth of a ton of husked ears per acre in favor of planting in hills. The results with fertilizers are summarized in the following table:

Fertilizer experiments with oats, mangels, fodder corn, and Swedish turnips.

Kind of fertilizer.	Fertilizer per acre.	Average yield per acre.					
		Oats. 5 yrs.; 74 tests.	Mangels. 5 yrs.; 41 tests.	Fodder corn.		Swedish turnips.	
				Whole crop. 6 yrs.; 43 tests.	Husked ears. 6 yrs.; 38 tests.	2 yrs.; 5 tests.	1903. 3 tests.
	Lbs.	*Bu.*	*Tons.*	*Tons.*	*Tons.*	*Tons.*	*Tons.*
Nothing	....	38.9	20.6	8.2	2.8	24.1	25.5
Nitrate of soda	160	46.3	26.5	9.7	3.2	28.9	32.1
Muriate of potash	160	43.8	24.6	9.8	3.1	28.6	39.9
Superphosphate	320	43.6	24.2	9.4	3.2	30.3	33.6
Complete fertilizer	213	48.7	25.4	9.6	3.3	32.1	34.9
Cow manure	40,000	....	....	....	....	33.5	38.1

The complete fertilizer application was composed of one-third of the quantity of nitrate of soda, muriate of potash, and superphosphate applied alone. The largest increase of Swedish turnips as compared with the unfertilized land was obtained with the complete fertilizer at a cost of 1.7 cts. per bu., of mangels with nitrate of soda at 2.3 cts. per bu., of oats with complete fertilizer application at 47 cts. per bu., and of fodder corn with muriate of potash $2.87 per ton.

The yields of the best varieties of grain crops are given in the following table:

Leading varieties in cooperative tests with grain crops.

Crop.	Number of tests.	Number of varieties tested.	Leading variety.	Yield per acre.	
				Straw.	Grain.
				Tons.	*Bu.*
Oats	104	3	Siberian	1.63	54.54
Six-rowed barley	32	3	Manshury	1.50	44.95
Hulless barley	18	2	Black Hulless	1.46	24.13
Spring wheat	13	3	Emmer	1.55	45.25
Buckwheat	2	2	Silver Hull	2.00	32.92
Field peas	14	2	Early Britain	1.65	32.59
Field beans	8	2	White Wonder	1.68	29.59
Bug-proof peas	20	2	Egyptian	1.03	16.27
Soy beans	3	2	Early Yellow	1.28	15.11
Corn for grain	16	3	King Philip	....	48.31
Winter wheat	25	3	Imperial Amber	1.61	24.93

The varieties of sweet corn tested and the number of days required for their growth for table use were as follows: Mammoth White Cory, 95 days; Crosby, 111 days; Country Gentleman, 125 days. Crosby appeared to lead in quality. Five varieties of potatoes grown in 227 tests gave the following yields: Empire State, 221.9 bu.; Burpee Extra Early, 172.6 bu.; Early Pinkeye, 164.1 bu.; Early Ohio, 125.2 bu.; Stray Beauty, 118.8 bu. Level culture has given slightly better yields than hilling. The average results for 4 years show that sprinkling seed potatoes with land plaster increased the yield about 9 bu. per acre throughout Ontario.

Culture experiments in 1902–3, A. DAMSEAUX (*Bul. Agr. [Brussels], 20 (1904), No. 1, pp. 34–43*).—The yields per are of the leading varieties of cereals under test in 1903 were as follows: Schlanstedt rye, 34 kg. of grain and 97 kg. of straw; Gros bleu spring wheat, 34 kg. of grain and 76 kg. of straw; Albert barley, 48 kg. of grain and 60 kg. of straw; and Kirsche oats, 45 kg. of grain and 80 kg. of straw.

An experiment was made to determine the influence of lime on the action of superphosphate. Sugar beats which in addition to superphosphate had received 4,000 kg. of lime per hectare developed well, indicating that the efficiency of the superphosphate was not diminished. When 8,000 kg. of lime per hectare was employed the quality of beets was reduced through deformity. It was also shown that barley was more sensitive to a heavy application of lime in connection with superphosphate than oats. The author concludes that where the application of lime is increased the quantity of superphosphate should be increased in proportion to avoid an excess of lime which in many cases renders phosphoric acid insoluble.

The study of the substitution of sodium for potash was made with oats and barley grown in pots. The yield of oats with a complete fertilizer was 12 gm. per pot; with the same application without potash, 6 gm.; with the complete application in which the potash was replaced with an equal quantity of sodium, 16 gm.; with potash alone, 2 gm.; and with sodium alone, 2.5 gm. The corresponding yields of barley were 11, 6, 8.6, 4.4, and 2 gm., respectively.

Among 11 varieties of sugar beets, Elite Kleinwanzleben led with a yield of 43,800 kg. of beets per hectare representing a value of 1,059.96 francs. The highest sugar content, 14.8 per cent, was obtained in Kirsche which variety also ranked high in purity.

Sulphocyanid of potash as a fertilizer interfered with the germination of barley and winter wheat, while the growth of oats seemed to be benefited. Sugar beets also proved very sensitive to this substance. Applying 300 kg. of sulphocyanid of potash and ammonia at planting reduced the yield of sugar beets by 1,800 kg. per hectare; the sugar content, 0.6 per cent; and the quotient of purity by 2.4 as compared with results obtained where an equal quantity had been applied a month earlier. Plats receiving barnyard manure together with nitrate of soda at the time of planting yielded 37,000 kg. of sugar beets per hectare with a sugar content of 14.20 per cent, while those receiving the manure in March and the nitrate at planting or the manure and part of the nitrate in March and the rest of the nitrate at planting yielded 37,400 kg. with 13.70 per cent of sugar and 38,400 kg. with 14.40 per cent of sugar, respectively.

The comparative yields of 6 varieties of fodder beets are reported. In the production of beets, Kirsche stood at the head with a yield of 91,200 kg. per hectare, containing 10.42 per cent of dry matter, while Dauerrunkel, the leading variety in dry matter, containing 14.41 per cent, stood third with a yield of 72,800 kg.

Equal quantities of seed were planted of 17 varieties of potatoes. The leading varieties, mentioned in the order of productiveness, were Professor Maercker, Up-to-date, Excelsior, and President Kruger.

A mixture of corn, vetches, peas, and horse beans produced from 20,000 to 28,000 kg. of green forage per hectare.

Experiments with leguminous plants at Danish State plant experiment stations, 1880-1899, N. P. NIELSEN (*Tidsskr. Landbr. Planteavl, 10 (1904), pp. 159-323*).—Final accounts are given of experiments with red, alsike, and white clover grown from seed of different origin, and also of a large number of comparative trials with kidney vetch, trefoil, alfalfa, and *Lotus tenuifolius*. Most of the experiments have been conducted for a period of 20 years under a great variety of soils and seasons, as, for instance, the red clover experiments, which were conducted on 27 different fields with over 1,000 seed samples of different origin, planted on 2,581 plats.

The average yields of red clover hay for 2 seasons on all fields compared as follows: Early varieties—Silesian, 100; Danish and Russian, 98; Bohemian, Moravian, and American, 95; Hungarian, Steiermark, and Galician, Rhine region and Holland, 88; English, 81; French, 79, and Italian, 25. Medium late varieties—American, 102; English, 99. Late varieties—Danish and Swedish, 116; Norwegian, 114; Russian, 109; Silesian and Galician, 107; American and English, 101. The following comparative data were obtained with alsike clover: Swedish, 100; Rhine region, 98; English, 97; Germany, 91; Canada, 83; North America, 80. In the average for 2 years the relative yields of white clover from seed of different origin stood as follows: Danish, 100; Italy (Lodi clover), 94; Holland, 92; America, 89; Pommern, 86; England, 80; Provstiet, 80; Silesia, 76; Germany, 73.

The seed of different origin and the characteristics of the seed market in the various regions are discussed, and it is shown that American red clover seed has undergone a marked improvement in quality during the 20 years under investigation. Placing the yields from Silesian seed at 100, those from American seed during successive 5-year periods were 81, 91, 95, and 96.

The principal results obtained with leguminous plants are summarized in the following table, the yields being given in hundredweight per Töndeland, or 1.36 acres.

Comparative yields of leguminous plants.

Crop.	Number of fields.	Number of seed samples.	Number of trial plats.	Yields of hay per Töndeland. First year. First cutting.	Second cutting.	Total.	Second year.	Total for both years.
				Cwt.	Cwt.	Cwt.	Cwt.	Cwt.
Early Silesian red clover	15	65	100	45.9	31.6	77.5	21.8	99.3
Alsike clover	17	119	170	39.9	13.7	53.6	27.5	81.6
White clover	16	130	173	25.6	8.5	34.1	13.1	47.2
Trefoil	15	36	68	46.5	6.9	53.4	19.1	72.5
Kidney vetch	16	18	22	65.7	4.7	70.4	....	....

Ten fields of alfalfa during 3 years yielded a total of 227.8 cwt. per Töndeland and 9 fields of sand lucern 225.2 cwt. per Töndeland.

Hungarian alfalfa seed produced the largest yields of hay in all trials. French alfalfa seed gave about 80 per cent of the yield obtained from Hungarian seed, while seed of other origin yielded in the following order: German, Italian, American, and Russian. The yields secured from American and Russian seed yielded only one-third to one-half of that obtained from Hungarian seed. Six series of trials were conducted at 2 different stations with red clover or kidney vetch mixed with alfalfa for the purpose of increasing the yields during the first and second year. The results shown in the following table were obtained on 6 different fields for the first 3 comparative trials and on 5 fields for the other tests.

Yields of hay from alfalfa seed sown alone or mixed with red clover or kidney vetch.

Seed sown.	Yields per Töndeland (1.36 acres).				
	First year.	Second year.	Third year.	Total.	Relative yields.
	Cwt.	*Cwt.*	*Cwt.*	*Cwt.*	
25 lbs. alfalfa seed	40.5	82.9	95.9	219.3	100
18 lbs. alfalfa, 6 lbs. red clover	73.5	65.3	58.8	197.6	90
12 lbs. alfalfa, 12 lbs. red clover	73.9	51.3	33.6	158.8	72
25 lbs. alfalfa	33.6	79.8	88.6	202.0	100
25 lbs. sand alfalfa	42.0	77.0	92.0	211.0	104
18 lbs. alfalfa, 6 lbs. red clover	70.5	66.4	50.2	187.1	93
20 lbs. sand alfalfa, 5 lbs. red clover	64.0	53.6	42.5	160.1	79
12 lbs. alfalfa, 12 lbs. red clover	69.9	48.7	29.1	147.7	73
18 lbs. alfalfa, 6 lbs. kidney vetch	43.7	72.1	65.9	181.7	90

The results show conclusively that in the same ratio as the red clover predominated during the first year, the yield is reduced during subsequent years, so that pure alfalfa seed gives about twice as much hay the third year as the mixture with 6 lbs. red clover seed, and about three times as much as the mixture with 12 lbs. of red clover seed.

The importance of well prepared and well kept alfalfa fields is emphasized, and mowing during the first year when the plant is in full bloom and again toward the end of September is recommended.—F. W. WOLL.

Crops grown on moor soils in different parts of Sweden, H. VON FEILITZEN (*Svenska Mosskulturför. Tidskr., 17 (1903), No. 5, pp. 317–320*).—The author collected statistical data from 21 counties of Sweden which show that 77 per cent of the farmers who settled on moorland plantations grow rye, 49 per cent grow barley, 100 per cent oats, 28 per cent potatoes, 43 per cent fodder beets, and 14 per cent ruta-bagas.—F. W. WOLL.

Experimental stations, E. CLIFTON, F. GILLANDERS, ET AL. (*New Zealand Dept. Agr. Rpt. 1903, pp. 337–359, pls. 28*).—A general report on the work of the different experiment stations in New Zealand is given, and brief notes on the results of culture tests with tobacco and potatoes and of fertilizer trials with potatoes, turnips, mangels, and pasture grasses are included. On the Ruakura Farm, top-dressing pastures with 56 lbs. each of kainit and bone dust on fourth-acre plats gave the best results, while the plat receiving 77 lbs. of Thomas superphosphate gave practically the same yield.

Cape barley yielded 53 bu. per acre at the Momohaki Farm. Pioneer and Tartar King oats produced a very heavy crop but were badly affected with rust. The average results for 4 years are in favor of superphosphate as a fertilizer for potatoes. In a potato variety test Findlay Scotia with a yield of 19 tons per acre headed the list. The use of fertilizer shows great increases in the yields of turnips.

List of Philippine agricultural products and fiber plants, F. LAMSON-SCRIBNER (*Philippine Bureau Agr. Bul. 5, pp. 47*).—A list of fruits and vegetables is alphabetically arranged according to the native or local names. Synonyms are recorded and the plants are briefly described. A list of Philippine Island fiber plants is arranged alphabetically by the scientific names. The local or native names, the distribution within the islands, the parts of the plant used, and the different uses are given.

The selection of varieties for special climatic and soil conditions, W. BESELER (*Illus. Landw. Ztg., 24 (1904), No. 14, pp. 145, 146*).—This article discusses the behavior of different varieties of wheat, oats, and rye under varying conditions and presents conclusions based on these data.

It is stated that as plants are products of the soil, varieties are as much influenced by their origin as breeds of animals. Most highly developed varieties of plants from regions having a favorable climate and a rich soil retain their qualities only under

conditions similar to those of their origin. Petkus rye is remarkable in its adaptation to a wide range of conditions, but this is believed to be due to its origin in an unfavorable climate and on a poor soil. The appearance of highly bred varieties of the other grains adaptable to different environments is considered not improbable.

Regions with poor soils and unfavorable climate have relatively few highly developed varieties. Ordinary varieties are not considered profitable, and it is recommended that in each locality the varieties best adapted to the conditions be selected by means of continued tests, and if these varieties are ordinary and undeveloped they should be improved by selection.

Experiments with grain and forage plants, 1899-1903, R. A. Moore (*Wisconsin Sta. Rpt. 1903, pp. 263-283; figs. 2*).—This article summarizes the work with grain and forage plants previously published and noted as follows: Tests of Grains (E. S. R., 12, p. 42; 13, pp. 36, 938); Tests of Forage Plants (E. S. R., 13, pp. 36, 938; 14, p. 957); Tests With Soy Beans (E. S. R., 13, pp. 36, 938); Variety Test With Soy Beans (E. S. R., 14, p. 957); Inoculation Experiment With Soy Beans (E. S. R., 14, p. 957); Tests With Cowpeas (E. S. R., 13, p. 938); Variety Tests With Cowpeas (E. S. R., 14, p. 957); Trials With Russian Vetch (E. S. R., 12, p. 42); Vetch as a Forage Plant (E. S. R., 13, pp. 36, 938; 14, p. 958); Trials With Growing Alfalfa (E. S. R., 13, p. 938); Trials With Growing the Alfalfa for Seed (E. S. R., 14, p. 957); Fall Seeding of Alfalfa (E. S. R., 14, p. 957); Tests With Turkestan Alfalfa (E. S. R., 14, p. 957); Variety Test of Rape, Dwarf Essex *v.* Victoria (E. S. R., 13, p. 36); Rape Sown with Oats (E. S. R., 13, p. 36); Variety Test of Rape, Dwarf Essex *v.* Puget Sound (E. S. R., 13, p. 938); and Rape Sown with Oats (E. S. R., 13, p. 938).

Causes of silage fermentation (*Wisconsin Sta. Rpt. 1903, pp. 243-249*).—This article is a summary of the work on silage fermentation previously published and noted as follows: Causes Operative in the Formation of Silage, by S. M. Babcock and H. L. Russell (E. S. R., 13, p. 37); Causes Operative in the Formation of Silage (2d article), by S. M. Babcock and H. L. Russell (E. S. R., 13, p. 939); Closed Circuit Respiration Apparatus, by S. M. Babcock and H. L. Russell (E. S. R., 13, p. 21); and Influence of Close Packing on Unavoidable Losses in Silage, by F. H. King (E. S. R., 13, p. 940).

Improving the quality of the brewing barley of this country, R. Wahl (*Reprinted from Amer. Brewers' Rev., 18 (1904), Nos. 3, pp. 89-91; 4, pp. 140-148; 5, pp. 190-194*).—These articles discuss at some length the importance of the albumen content of barley to the brewing industry. The author presents his views with reference to American barley, and reviews the opinions of different brewers and investigators at home and abroad.

Analyses of American barleys from different localities are reported. All 6-rowed varieties, excepting those from California, contained over 10 per cent of albumen, ranging from 10.33 per cent in a barley from Wisconsin to 15.16 per cent in one from Minnesota. The average percentage of husk in the 6-rowed varieties examined was about 11.75 per cent, the range being from 10.43 per cent in New York State barley to 14.10 per cent in California barley from the San Joaquin Valley. The measurements of the kernels of the different varieties are also given, and the methods of analyses and of examinations are briefly described. The history of American barley and barley culture is noted.

Chemical composition of beans, R. Bolliger (*Bol. Agr. São Paulo, 5. ser., 1904, No. 3, pp. 125-131*).—The chemical composition of 37 varieties of beans, including soy beans, is reported.

Clover, F. W. Card and A. E. Stene (*Rhode Island Sta. Rpt. 1903, pp. 209-213, figs. 2*).—Preliminary tests with clover were made to determine whether seed produced on acid soil shows increased resistance to soil acidity. Clover seed from different sources were sown in pots on acid soil of different texture and fertility. The results obtained are not considered as carrying much weight, but they seemed to

indicate that a difference in the ability of plants to resist acidity exists, and that in this experiment Mammoth Red Clover grew better on acid soil than medium red clover.

The effect of a lack of potash on clover and timothy, H. VON FEILITZEN (*Svenska Mosskulturför. Tidskr., 17 (1903), No. 5, pp. 365–368; 18 (1904), Nos. 1, pp. 33–44; 2, pp. 96, 97*).—A brief description is given of experiments with a so-called potash fertilizer which was found to consist of ground feldspar. If the increase in yield of green substance on the plat receiving 100 kg. potash in 37 per cent potash salt be placed at 100, the same amount of potash in the fertilizer gave a yield of 7, and twice this amount, a yield of 43. The plants grown on the unfertilized plats or upon those receiving applications of ground feldspar developed very slowly and made a weak growth; a great many yellowish-green specks appeared on the leaves, indicating a partial destruction of the chlorophyll, very likely due to the absence of soluble compounds of potash. Colored and other reproductions of the appearance of the plants at the time of harvesting accompany the report.

The analyses made of the hay harvested on the different plats showed that the potash content of the hay grown on the unfertilized or ground feldspar plats ranged from 0.600 to 0.635 per cent, while that grown on the plats receiving 37 per cent potash salt contained 1.105 per cent. On these same plats the soda content of the hay ranged from 0.140 to 0.245 per cent, as against 0.020 per cent on the potash plats, showing a relation of potash to soda as 100:23 to 39 in one case, and in the other as 100:2. If the amounts of potash applied on the different plats be compared with those contained in the harvested crop, it is shown that only 4.8 to 8.6 per cent of the potash in the feldspar was utilized by the crop, while in the case of the potash fertilizer 92.8 per cent reappeared in the crop harvested.—F. W. WOLL.

Selecting and preparing seed corn, P. G. HOLDEN (*Iowa Sta. Bul. 77, pp. 169–234, figs. 47*).—This bulletin gives directions for the production, storing, and purchase of seed corn; reports results of experiments with corn at the station, and points out at some length, by means of illustrations and discussions, the characteristics to be sought in the selection of kernels, ears, and plants. The following points are considered: Form, size, and type of kernels, shape and size of ears, position and arrangement of kernels on the cob, proportion of corn to cob, barren plants, uniformity in the height of ears upon the stalk, pollination and germination.

The productivity of different ears of corn was compared by planting the most perfect kernels from 102 of the best ears. The records show that there was a variation between the individual ears in yield from 36.06 bu. to 90.56 bu. per acre, in stand from 43 per cent to 96.5 per cent, in broken stalks from 41 to 258 or from 8 per cent to 64 per cent, in barren stalks from 6 to 79 or from 1.5 per cent to 21.5 per cent, and in the number of suckers from 0 to 106 or 21 per cent. These extremes in all cases showed a marked difference in the yield. The 10 best ears averaged 83.71 bu. per acre and the 5 poorest 40.05 bu., while the entire series of 102 ears gave an average yield of 67.09 bu.

Records of corn planter tests presented show that the edge drop planters gave much better results in the number of times 3 kernels were dropped in dropping 500 hills than the planters provided with the common round hole plates.

In a shrinkage experiment begun October 24, the corn under test had lost 12.60 per cent in weight by February 27. Rates of shrinkage were also determined for 7 different varieties. Nashes Early Yellow, which was perfectly matured when the test was begun October 31, showed a shrinkage of 4.93 per cent on January 9, while in immatured Reid, the loss in weight for the same period amounted to 17.49 per cent. The shrinkage in 4 leading varieties of field corn, for 5 months after husking and cribbing, is shown in the following table:

Shrinkage by months in four varieties of corn in the ear.

Date.	Mammoth Red.	Kegley Golden Beauty.	Iowa Silver Mine.	Yellow Farm.
	Per cent.	*Per cent.*	*Per cent.*	*Per cent.*
October 25	0.00	0.00	0.00	0.00
November 25	7.60	6.66	6.54	7.36
December 25	9.12	7.71	8.00	8.52
January 25	11.40	9.82	9.80	10.85
February 25	12.92	11.57	12.09	12.79
March 25	14.82	13.23	13.45	14.72
April 25	20.53	18.24	18.90	19.37
May 25	20.53	18.59	19.27	19.76
June 25	22.05	20.35	20.00	21.31
July 25	22.05	21.40	21.09	21.70

Of 46 varieties of corn from various parts of the State the 10 best gave an average yield of 77.46 bu. per acre and the 10 poorest 27.89 bu. The yields of the entire list ranged from 7.62 bu. to 91.44 bu. per acre. The lower yields were largely due to a poor stand, but some varieties, even with a poor stand, gave comparatively large yields.

The different steps in the selection of seed ears and kernels are described. A score card, with an explanation of points in corn judging, concludes the bulletin.

Sea Island cotton in the United States and the West Indies, D. MORRIS and J. R. BOVELL (*West Indian Bul., 4 (1904), No. 4, pp. 287–374, figs. 7*).—This article is mainly a report on the culture of Sea Island cotton in the United States, and contains largely information obtained and observations made on a visit to the regions where the long staple cotton is grown. The different steps in the culture of the crop are discussed and preparation of the fiber for market and use of the seed are described. Notes on insect pests and plant diseases injurious to cotton are given.

On the influence of manganese salts on flax, Y. FUKUTOME (*Bul. Col. Agr., Tokyo Imp. Univ., 6 (1904), No. 2, pp. 137, 138, pl. 1*).—A joint application of iron and manganese had a marked effect on the growth of flax plants, while each alone, given at the rate of 0.4 gm. per pot of 8 kg. of soil, showed but a small increase in yield over the check test. An application of 0.02 gm. of cobalt nitrate per pot also exerted a stimulating influence.

Maguey in the Philippines, H. T. EDWARDS (*Philippine Bureau Agr., Farmers' Bul. 10, pp. 14*).—A popular bulletin describing the maguey plant, its history and importance, and giving instructions regarding its culture and the treatment of the fiber.

Comparative value of different varieties of mangels, T. REMY (*Illus. Landw. Ztg., 24 (1904), No. 16, pp. 169–172, figs. 12*).—Seventeen varieties were compared and the results obtained in the total yield and in the production of dry matter tabulated. Each variety is briefly described. The Eckendorf variety produced the highest tonnage of beets per acre. Carter half-sugar beet, which stood first in the production of dry matter, ranked thirteenth in the yield of the beets.

Breeding oats resistant to lodging, A. KIRSCHE (*Illus. Landw. Ztg., 24 (904), No. 20, p. 217; Deut. Landw. Presse, 31 (1904), No. 20, p. 171*).—Measurements of the length and strength of internodes of plants from the breeding nursery are given in tables, and methods of obtaining the data are described.

In breeding varieties resistant to lodging, the lower internodes should be strengthened because the greatest strain falls on this part of the stem. The weight of the stem, according to the author, was no indication of its strength, but, in general, strong lower internodes indicated good strength in the rest of the culm. The lower internode should be shortened, but a plant with a short internode should be used for breeding purposes only when the stem shows good strength. In these tests the strength was determined by placing the part of the stem to be tested upon 2 points,

10 cm. apart, and suspending a weight from the middle. The carrying or sustaining capacity of the different internodes is given in grams.

Ten experiments with potatoes, and potato culture in New England, F. W. RANE and H. F. HALL (*New Hampshire Sta. Bul. 111, pp. 109–130, figs. 8*).—The results of a series of fertilizer experiments and of a variety test are reported. Applications of 1,500 lbs. each of Stockbridge potato manure and of home-mixed fertilizer gave practically equal yields but there was a saving of approximately $8.68 per acre in favor of home mixing. Both applications contained 3 per cent of nitrogen, 6 per cent of phosphoric acid, and 10 per cent of potash. The home-mixed application consisted of 150 lbs. of nitrate of soda, 112½ lbs. of sulphate of ammonia, 565½ lbs. of boneblack, and 300 lbs. of muriate of potash. A comparison between the New York and New Jersey home-mixed formula and the New Hampshire formula indicated that the 2 were of about equal value.

A potash test was made to determine how much potash can be used economically. The plat without potash produced a fair crop. The use of 150 lbs. of muriate of potash produced an increase of 30 bu. of marketable potatoes at a cost of about 11 cts. per bu., 300 lbs. increased the yield by 46 bu. at a cost of 14 cts. per bu., and 450 lbs. by 48 bu. at a cost of 20 cts. per bu. The application of 300 lbs. of muriate of potash or 10 per cent of potash in the fertilizer formula is considered best.

Comparative results between applying the commercial fertilizer all in the hill or one-half in the hill and the remainder broadcast showed no material difference. Fifteen cords of barnyard manure per acre increased the yield by 127 bu. of marketable potatoes and where 750 lbs. and 1,500 lbs. of the fertilizer formula were applied with this quantity of manure the yields were increased by 107 bu. and 101 bu. of marketable potatoes respectively. Larger applications of commercial fertilizer did not give as good results. In general, plowing under barnyard manure gave better results than harrowing it in. An experiment in applying the commercial fertilizer above and below the seed resulted in the best yields from applying it above the seed. The results were the same whether the 15 cords of barnyard manure were used in conjunction with the fertilizer or not.

Brief descriptions of 50 varieties of potatoes are given, and notes on modern potato culture are presented. The average comparative yields of a list of varieties are shown in a table.

Variety tests with potatoes, A. RINDELL (*Landtbr. Styr. Meddel., 1903, No. 44, pp. 28, 29*).—The results with 15 varieties showing the yields, starch content, disease-resisting power, and keeping quality are reported.—F. W. WOLL.

On the practical application of manganous chlorid in rice culture, K. ASO (*Bul. Col. Agr., Tokyo Imp. Univ., 6 (1904), No. 2, pp. 131–133*).—Two square plats of 30 square meters each which had not been manured for several years received each 27 kg. of barnyard manure, 15.5 kg. of night soil, 230 gm. of double superphosphate, and 570 gm. of wood ashes. One of the plats received in addition 25 kg. of manganic oxid in the form of manganous chlorid. The use of manganic oxid increased the yield of husked full grains of rice by one-third. A similar result was obtained by Nagaoka, who applied the same amount of manganic oxid in the form of the sulphate.

The stimulating action of manganese upon rice, M. NAGAOKA (*Bul. Col. Agr., Tokyo Imp. Univ., 5 (1903), No. 4, pp. 467–472*).—Preliminary experiments having shown that manganese sulphate in small quantities exerted a favorable influence on the development of various plants, it was determined to carry on an experiment with rice under field conditions.

Equal areas of a rice field were marked off and manganese sulphate applied in such quantities that the amount of manganic oxid was equivalent to from 10 to 55 kg. per hectare. The crop was harvested in November, and the yield in grain and straw is shown in tabular form. There was found to be a progressive and decided increase in the plats receiving manganese sulphate, up to the one receiving 25 kg. per hectare,

beyond which there was a gradual falling off of the yields. The author compares the cost and increased yield, from which it appears that an addition was obtained in the crop that was equal to 4 times the cost of the chemical applied.

On the stimulating action of manganese upon rice, M. NAGAOKA (*Bul. Col. Agr., Tokyo Imp. Univ., 6 (1904), No. 2, pp. 135, 136*).—Manganese compounds applied the previous year had increased the yield of paddy rice (see above), and this season the residual effects of these applications were observed. The best yield was obtained where manganese sulphate had been applied at a rate which furnished 30 kg. of manganic oxid per hectare, while the yield on the soil which had received 25 kg. was nearly as large. The increase over the soil which had been manured but had received no manganese was 16.9 per cent, while the maximum of increase for the first year was 37 per cent.

Progress of the beet-sugar industry in the United States, C. F. SAYLOR (*Washington: Government Printing Office, 1904, pp. 184*).—Earlier annual reports on the beet-sugar industry have been previously noted (E. S. R., 15, p. 356). This report discusses the development of sugar-beet production and of beet-sugar manufacture in the different States, compares the culture of sugar beets with growing other crops, points out the influence and economic effects of the industry, and gives general cultural directions.

The quality and source of our sugar-beet seed supply is considered, and the results obtained with home-grown beet seed and in germination tests with home and foreign grown seed, made in the Seed Laboratory of the Bureau of Plant Industry of this Department, are given in tables. The duration of the germination tests was in all except 2 cases 6 and 14 days. The home-grown seed excelled in every respect with the exception of Hoerning seed of Improved Kleinwanzlebener, which in the 14-day test produced the greatest number of sprouts.

The average sugar content of 185 beets grown in Washington from seed produced in that State was 20.21 per cent. Other results obtained by the Bureau of Plant Industry in cooperation with several experiment stations are given in the tables below:

Summary of analyses of beets grown at Geneva, N. Y., fall of 1903.

Kind of seed used.	Sugar content.	Purity coefficient.	Yield per acre.	Sugar × purity.	Sugar × purity × yield.
	Per cent.	*Per cent.*	*Tons.*		
German No. 1	17.4	88.1	18.61	15.33	28.53
German No. 2	17.3	86.3	17.48	14.93	26.10

German No. 1 and German No. 2 represent selected seed and German No. 3 commercial seed, while the other samples were produced in the States mentioned.

Summary of analyses of beets grown at Holland, Mich.

Kind of seed used.	Area.	Sugar content.	Yield per acre.	Sugar × yield.
	Acres.	*Per cent.*	*Tons.*	
Utah	0.23	16.00	21.70	34.72
Washington	.35	13.40	15.80	21.17
California	.38	15.00	11.00	16.50
Kleinwanzlebener (average for 3 fields)		15.10	11.13	16.82
Michigan	.13	12.50	13.70	17.12
German No. 1	.25	13.10	8.00	10.48
Hoerning (Germany) (average for 2 fields)		13.25	11.50	15.17

The Hoerning and Kleinwanzlebener seed was obtained from commercial lots. The Kleinwanzlebener was compared with the seed from Utah, Washington, and California, and the Hoerning with seed from Michigan and German No. 1.

The factory and farm results reported for 1903 include the climatic conditions prevalent during the season, the tonnage of beets worked in each State, the amount of sugar produced and the features of improvement and general conditions prevalent in each factory district. Statistics of results for the year in a total of 49 factories are tabulated. A series of letters discussing sugar-beet growing are reproduced, and the matter of State bounties is briefly reviewed.

In 1903, 242,576 acres of beets producing an average of 8.418 tons per acre were harvested and the average price per ton was $4.966. The quantity of beets worked was 2,076,494 tons from which 481,209,087 lbs. of sugar were obtained.

Experiments with sugar beets (*Wisconsin Sta. Rpt. 1903, pp. 293–301*).—This article reviews work previously published and noted as follows: Sugar Beet Production: Possibilities for a New Industry in Wisconsin, by W. A. Henry (E. S. R., 9, p. 133); Sugar-Beet Culture in Wisconsin During 1897, by F. W. Woll (E. S. R., 10, p. 39); Sugar-Beet Investigations in Wisconsin During 1898, by F. W. Woll (E. S. R., 11, p. 143); Sugar-Beet Culture in Wisconsin During 1899, by F. W. Woll (E. S. R., 13, p. 44); Experiments in Sugar-Beet Culture During 1900 and 1901, by F. W. Woll and R. H. Shaw (E. S. R., 13, p. 946); and Sugar-Beet Experiments During 1902, by F. W. Woll and R. A. Moore (E. S. R., 14, p. 961).

The results for 1903 show that Kleinwanzleben yielded at the rate of 52,760 lbs. of beets per acre, representing, at an average sugar content of 11.82 per cent, a production of 6,238 lbs. of sugar. A practically perfect stand had been obtained from the use of seed at the rate of 23 lbs. per acre. Subsoiling increased the yield of beets and of sugar only where phosphate and potash or nitrate, phosphate, and potash were applied. It is believed that in these cases the effect of retarding maturity caused by subsoiling was overcome by the use of the fertilizers. As in previous years the fertilizer tests show that on a suitable soil in a good state of fertility, commercial fertilizers are of little benefit and sometimes remain without effect altogether.

On the effect of artificial fertilizers on the quality of sugar beets, M. WEIBULL (*Landtmannen, 14* (*1903*), *No. 38, pp. 601–604*).—A discussion of the results of fertilizer experiments with sugar beets conducted during the season of 1902 (E. S. R., 15, p. 570).—F. W. WOLL.

Sugar-cane experiments in Cuba, E. F. ATKINS (*Agr. News* [*Barbados*], *3* (*1904*), *No. 56, p. 179*).—The tabulated results show that several Barbados seedlings as well as D 95 and Demarara Seedling have given good results. Harvard 208, a Cuban Seedling and a cross between a Crystalline and a Ribbon cane, contained 17.20 per cent sucrose, with a purity of 95.

Sugar-cane experiments in the Leeward Islands, 1902–3, F. WATTS (*Imp. Dept. Agr. West Indies, Rpt. Expts. Antigua, and St. Kitt's, 1902–3, I, pp. 68*).—This report on experiments with varieties of sugar cane has been noted from another source (E. S. R., 15, p. 577).

Sugar-cane experiments in the Leeward Islands, 1902-3, F. WATTS (*Imp. Dept. Agr. West Indies, Rpt. Expts. Antigua and St. Kitt's, 1902-3, II, pp. 115; abs. in Imp. Dept. Agr. West Indies, Pamphlet 30, pp. 78*).—The results of an extensive series of fertilizer experiments are tabulated in detail. The series consisted of 36 tests, and each was repeated 8 times with plant canes and 6 times with ratoon canes. The conclusions and recommendations based on the results are briefly summarized as follows:

"Plant canes, when the field in which they have been planted has been properly tilled and manured with pen manure, require no artificial manure. When the soil is in good condition, but it has been found impossible to give the proper dressing of pen manure, then artificial manures may prove remunerative: Under these circumstances it is suggested that either 1½ to 2 cwt. of sulphate of ammonia, or 2 to 2¾ cwt. of nitrate of soda be given in one application. A small additional profit will probably follow from the use of ¾ to 1 cwt. of sulphate of potash together with phosphate, either 1½ to 2 cwt. of basic phosphate, or a similar amount of superphosphate. All of these manures should be given early.

"For ratoon canes nitrogen is very necessary, and this may take the form of 2 to 3 cwt. of nitrate of soda, or 1½ to 2½ cwt. of sulphate of ammonia. Remunerative results will be obtained without the use of potash or phosphate, but a small additional profit may be expected from their use; ¾ cwt. of sulphate of potash, and 1½ to 2 cwt. of either basic phosphate or superphosphate may be employed. It is quite clear, however, that nitrogen, in a rapidly acting form, must be used if good ratoon crops are to be grown."

Dividing the nitrogen into 2 applications proved detrimental, the effect being more marked where both potash and phosphoric acid were given with the first application of nitrogen, and much more so when potash alone in considerable quantities was applied at that time.

A comparison between the tonnage of canes and the pounds of sucrose in the juice is reported for plant canes and ratoons, and the conclusion is drawn that "the same inferences for the guidance of the planter would be arrived at by argument derived from the tonnage of cane as from the weight of sucrose." The kind of commercial fertilizers used seemed to have affected the quantity of the sugar in the cane but slightly. Nitrogen mixed with potash and phosphoric acid showed a slight increase of sucrose per ton of cane and when used alone a slight decrease. There was no indication that phosphoric acid increased the sucrose per ton of cane. In the ratoon canes the variation was somewhat greater than in the plant canes.

The conclusion is drawn "that manures in such quantities as are likely to be used in ordinary practice in the Leeward Islands exert their influence chiefly in altering the weight of cane per acre without profoundly altering the weight of sucrose to the ton of cane."

Report of the agricultural work for 1901-1903, J. P. D'ALBUQUERQUE and J. R. BOVELL (*Rpt. Agr. Work, Imp. Dept. Agr. West Indies, 1901-3, pp. 121*).—The results of fertilizer experiments with sugar cane on different plantations are tabulated in detail and briefly discussed.

At Dodds the best yields were obtained from a plat fertilized at the rate of 30 tons of barnyard manure, 40 lbs. of nitrogen as dried blood, 36.64 lbs. of phosphoric acid as superphosphate of lime, and 60 lbs. of potash as sulphate of potash per acre. This plat produced 34.7 tons of cane per acre, or 10 tons more than the no-nitrogen plat. Basic slag proved more effective than superphosphate of lime. Sixty pounds of potash in the form of the sulphate, applied one-half in January and one-half in June, gave the highest increase of the potash applications. A plat which had received 50 tons of barnyard manure yielded 33 tons of cane per acre, and this result is believed to indicate that this application will maintain the yield without the use of commercial fertilizers.

At Four Square plantation the plats received 27 tons of barnyard manure in November, 1901, before the crop was planted. In addition, different applications of commercial fertilizers were used. The application of nitrogen alone showed no increase in yield, but where 60 lbs. of nitrogen as sulphate of ammonia were applied with 45.8 lbs. of phosphoric acid as basic slag and 100 lbs. of potash, the increase amounted to 2½ tons. Small quantities of nitrogen were unsatisfactory, but the use of from 80 to 100 lbs. per acre gave good results. Phosphatic manures apparently gave a small increase, and in general superphosphate was more effective than basic slag. Liming increased the yield by from 3 to 4½ tons per acre. The use of 25 lbs. of potash as sulphate also gave an increase in yield.

Experiments at Hopewell plantation were conducted with plant canes, first ratoons, and second ratoons. The plant cane received as a general application 27 tons of barnyard manure per acre; first ratoons, 30 tons; and second ratoons, 40 tons. In the plant-cane experiments a complete commercial fertilizer showed an increase of about 6 tons per acre, and nitrogen was the most important constituent in producing this result. In this case basic slag was more effective than superphosphate. The phosphoric acid and nitrogen furnished in the commercial fertilizers applied to the first ratoons caused an increase in yield of from 8 to 10 tons of cane per acre. The phosphatic manures of this test were equally effective. Where no barnyard manure was used phosphoric acid and potash were without effect in the experiments with second ratoons.

A complete application of commercial fertilizers without manure produced a crop of 20 tons per acre. Basic slag remained without effect and superphosphate produced a small increase. Potash in applications up to 75 lbs. per acre caused a large increase in yield. With the application of manure, nitrogen up to 75 or 100 lbs. per acre produced a larger increase, but when the quantity reached 100 lbs. an addition of the potash and phosphoric acid resulted in no further increase. In a series of tests made on 1-acre plats, it appeared that the use of 18.32 lbs. of phosphoric acid as superphosphate and 50 lbs. of potash as sulphate, in addition to 100 lbs. of nitrogen upon the first ratoons, increased the yield about 1½ tons. The use of nitrogen as nitrate of potash showed no gain.

The results of a tillage experiment showed a difference of 2½ tons of canes per acre. Subsoiling and manuring and cultivating in the usual manner gave the best yield. The smallest yield was obtained where the plats were ridged with a disc plow turning under barnyard manure 8 in. deep, the cane planted in rows at the bottom and cultivated with the Diamond cultivator.

The experiments with seedling and other varieties of canes here reported have been noted from another source (E. S. R., 15, p. 671).

Tobacco work in 1903, E. H. Jenkins (*Connecticut State Sta. Rpt. 1903, pt. 5, pp. 440–444*).—A description is given of work in the selection of tobacco seed for the purpose of obtaining a leaf of desirable quality, and at the same time uniform in size, shape, and weight.

An acre under shade was set with plants from 12 different varieties of tobacco seed, comprising 7 of the Sumatra type, 2 of the Cuban, and 1 each of the Connecticut broadleaf, Connecticut Havana, and Kentucky White Burley. The plants most desirable with reference to number, size, and shape of leaves were retained as seed producers, while all others were topped. At the beginning of flowering 2 or 3 of the best plants were selected from each plat, and all precautions were taken to prevent cross pollination, so that the seed produced is entirely the product of the plant upon which it grew. It is believed that these seeds will produce crops much more uniform in character than the corresponding crops of this season, and that the shape and size of the leaf will show some improvement.

Notes on the culture and handling of tobacco (*Bol. Tec. Coltiv. Tabacchi, Scafati [Salerno], 3 (1904), Nos. 1, pp. 54–85; 2, pp. 47–79*).—A series of brief reports

on experimental work with tobacco in different localities in Italy is given. The results of tests of varieties, starting the seed in seed beds, determining the cost of growing the crop and of curing in different ways are noted.

HORTICULTURE.

A continuation of Bulletin No. 74 on onions, also notes on strawberries and varieties of vegetables, G. Cotte (*Oregon Sta. Bul. 77, pp. 16, pls. 5*).—Bulletin No. 74 of the station (E. S. R., 14, p. 1063) presented the results of some experiments in transplanting onions as compared with seed sown in the open field. That work has been continued and further details are given in the present bulletin. The following table shows the relative yields of different varieties of onions when started in a hotbed from seed and transplanted later as compared with the yields obtained from seed sown in the field.

Yield per acre of transplanted and field-sown onions in 1903.

Variety.	Transplanted.	Field sown.	Increase due to transplanting.
	Bushels.	*Bushels.*	*Bushels.*
Sutton Ailsa Craig	992	393	599
Australian Brown	648	525	123
Red Wethersfield	432	263	169
Silver Skin	432	280	152
Yellow Globe	770	485	285

The onions in the above table have been grown on unmanured land and without irrigation. The transplanted onions were sown in boxes on January 22 and transplanted to the open field, without previous pricking out, between March 21 and 25. The seed for the open-field crop was sown in all cases February 28. The table brings out clearly the increased yields obtained with all varieties with the earlier seeding and transplanting.

Brief descriptions are given of each of the varieties in the table and of 3 other varieties not in the test. Descriptive notes are also given on 5 varieties of garden peas, 1 of cucumbers, 2 each of corn and cabbage, and 16 varieties of strawberries. Some practical suggestions on cultural methods accompany the notes on strawberries.

Variety tests with kohl-rabi and carrots, T. Remy (*Illus. Landw. Ztg., 24 (1904), Nos. 26, pp. 291–293; 27, pp. 303, 304, figs. 12*).—The average yield of kohlrabi was 47,500 kg. per hectare, with 5,200 kg. of dry matter. White Altmark Giant ranked first in yield. Among a number of varieties for table use, Yellow Apple led with a yield of 50,100 kg. per hectare. In the test with carrots, Ottersberg Mousetail stood first with a production of 8,220 kg. of dry matter per hectare. Kuepper Rhenish Giant gave the highest yield of carrots. Bertram Red Sudenberg proved a productive table variety.

Selection of garden carrots, Denaiffe (*Jardin, 18 (1904), No. 410, pp. 89, 90, figs. 2*).—Suggestions are given for improving garden carrots by selection. To prevent crossing, fields of carrots should be 600 to 800 meters (120 to 160 rods) apart.

Culture of cauliflower seed in Denmark, G. Nyeland-Brandt (*Jardin, 18 (1904), No. 410, pp. 85, 86, fig. 1*).—An account of Danish methods of growing cauliflower seed. It is stated that 80 per cent of the seed is exported to America.

Report of the horticultural division, F. W. Card and A. E. Stene (*Rhode Island Sta. Rpt. 1903, pp. 199–229, figs. 9*).—This report contains a detailed record of the blooming period of 82 varieties of apples, 7 of cherries, 35 of pears, and 31 of plums for the years 1899–1903; an account of further work to test the effect of nitrogen, potash, and sugar, respectively, upon the color of flowers (E. S. R., 15, p. 151);

work supplemental to that reported during the years 1898 to 1902 on sweet corn selection (E. S. R., 15, p. 151); experiments on the propagation of huckleberries, or blueberries by stem cuttings, root cuttings, and root grafts; crossing experiments with Ilex and with strawberries; and miscellaneous work like the improvement of clover by selection; the use of gasoline as a remedy against enemies of the squash, cucumber, and pumpkin; spraying peaches with Paris green and Bordeaux mixture and various methods of treating posts to increase their durability, all of which are noted elsewhere in this number.

Further work in fertilizing such flowers as phlox, balsam, branching aster, carmine, peach blossom, and 10 weeks' stock with nitrogen potash, or sugar, respectively, resulted in showing no influence whatever for these different materials in intensifying the color of the flowers produced. Since these results agree with those of the previous year it is believed fair to assume "that under ordinary field conditions any reasonable application of nitrate of soda, of muriate of potash, or of sugar will not materially intensify or reduce red color in flowers."

In the sweet corn experiment selection has proceeded along two lines. "In one line seed has been chosen from the lower ear of stalks bearing the largest number of ears; in the other case from the upper ear of stalks bearing the largest number of ears." The results secured in 1902 were in accord with those of previous years, and show that more progress may be expected by selecting seed from the upper ear than from the lower one. The notion, therefore, that to increase the number of ears, one should choose always from the lower one because that is the last one developed, is shown to be erroneous. Further work along this line will therefore be discarded. Whatever further selection may be made will be from upper ears or from well-developed ears only.

The propagating experiments with blueberries were made with the swamp or high-bush blueberry (*Vaccinium corymbosum*). Seeds of this blueberry germinate readily, but growth is very slow. Attempts were therefore made to see if it could not be propagated in the greenhouse by root or stem cuttings or by root grafts. Such material as moss, sand, garden soil, soil taken from about the roots of wild parent plants, and combinations of these were used as materials in which to start the plants. The cuttings formed shoots readily, but in only a few cases did they form roots. In fact, the main difficulty seemed to lie in inducing the formation of roots.

Very promising results were secured with both root grafts and root cuttings where these were started in moss in which soil taken from about the wild plants was mingled and moderate bottom heat used. In all cases better results were secured when the plants were rooted in moss and soil than when rooted in sand and soil. From the results secured in these experiments the author is hopeful that it may be possible to use miscellaneous New England blueberry roots with selected scions for propagating blueberries, and while such stock can not be sold cheap, it may, nevertheless, be produced at a fair price.

The behavior of plants now growing at the station in cultivated ground indicates that while they may be slow in gaining a foothold they grow more rapidly as time goes on, and there seems to be no reason why they should not give good results in garden culture. Attempts to cross *Gaylussacia resinosa* and *Vaccinium corymbosum* failed. In breeding experiments with Ilex, attempts have been made to cross *Ilex verticillata*, the winter berry, with *Ilex glabra*, the ink berry, the purpose being to combine the red fruit of the winter berry with the evergreen foliage of the ink berry. Thus far the different crosses have resulted in failure.

No results of striking importance have yet been secured in the work with strawberry seedlings.

Miscellaneous horticultural work (*Wisconsin Sta. Rpt. 1903, pp. 368–390, fig. 1*).—This is a summary of the following articles, previously published by the station:

Subwatering Greenhouse Benches, by E. S. Goff and F. Cranefield (E. S. R., 9, p. 557; 13, p. 957); Apple Culture, by E. S. Goff (E. S. R., 8, p. 49); Experiments in Irrigation, by E. S. Goff (E. S. R., 8, pp. 310, 696); Effects of the February Freeze of 1899 upon Nurseries and Fruit Plantations in the Northwest, by E. S. Goff (E. S. R., 11, p. 930); Effects of Continued Use of Immature Seed in the Tomato, by E. S. Goff (E. S. R., 13, p. 47); The Effects of Continued use of Immature Seed in Indian Corn, by E. S. Goff (E. S. R., 13, p. 39); The Influence of Heredity upon Vigor in the Potato, by E. S. Goff (E. S. R., 12, p. 43); An Experiment to Determine the Influence on Yield and Size of Fruit, of Pinching the Tips of Growing Shoots of Raspberries, by E. S. Goff and F. Cranefield (E. S. R., 12, p. 51; 13, pp. 51, 953; 14, p. 966); Injurious Insects, by E. S. Goff; Noxious Weeds, by E. S. Goff (E. S. R., 6, p. 145; 11, p. 749); Experiments in the Curing and Culture of Tobacco, by E. S. Goff (E. S. R., 8, pp. 303, 685); Small Fruits in 1898, by E. S. Goff (E. S. R., 11, p. 150); and Is the Ripening Season of a Pistillate Strawberry Affected by the Blooming Period of Its Pollenizer? by E. S. Goff (E. S. R., 10, p. 755).

In addition, a list is given of numerous other papers on horticultural topics published by the station.

The origin of development of fruit buds (*Wisconsin Sta. Rpt. 1903, pp. 360–362*).—This is a summary of the following article, previously published by the station: The Origin of the Early Development of the Flowers in the Cherry, Plum, Apple, and Pear, by E. S. Goff (E. S. R., 12, p. 22; 13, p. 18).

Fruit growing, with a selected list of varieties for New Hampshire, F. W. Rane (*New Hampshire Sta. Bul. 105, pp. 24, figs. 21*).—Popular directions are given in this bulletin for the growing of a number of orchard and small fruits. It is believed that fruit should and can be much more largely grown throughout New Hampshire than it is at the present time. Special attention is given to recommendations of varieties of each of the different fruits. Lists of suitable varieties for planting in the different parts of the State are given for plums, apples, peaches, pears, grapes, cherries, quinces, blackberries, raspberries, currants, gooseberries, and strawberries.

The fruit garden, G. Bunyard and O. Thomas (*London: Country Life; New York: Charles Scribner's Sons, 1904, pp. XIII+507, pls. 9, figs. 62, dgms. 245*).—Very complete directions are given in this work for the culture of all the usual hardy and house fruits grown in Great Britain. Special attention has been given to the matter of pruning, and this phase of the subject is very fully illustrated.

Besides cultural directions, descriptions are given of a large number of varieties of each of the fruits discussed, and outline drawings made. Tomatoes and melons are considered as well as the nursery propagation and management of trees and the construction of fruit houses. Chapters are also given on fruit culture in America, France, and the Channel Islands. That on America was written by H. E. Van Deman, and is an outline survey of the whole field.

Experiments in orchard management in New England, F. W. Rane (*New Hampshire Sta. Bul. 110, pp. 85–106, figs. 6*).—This bulletin discusses in a popular manner methods of orchard culture and management in New England. One method of renovating an old orchard which has been found successful at the station consists in breaking up the soil in spring and, after thoroughly preparing it, planting to dwarf peas or bush beans. By this method the ground is frequently cultivated, the pods pay for the labor, and the crop is turned under early enough so that a cover crop can be planted.

It is believed that the Hitchings method of mulching the orchard by mowing and letting the crop remain on the ground may possess some advantages for New England. One instance is cited in which an orchard of about 10,000 trees is thus cultivated. Among other topics, methods of manuring, pruning, thinning, spraying, picking, and winter protection of orchards are discussed.

New York apples in storage, S. A. BEACH and V. A. CLARK (*New York State Sta. Bul. 248, pp. 83–152, pls. 2*).—An account is given in this bulletin of the natural season of ripening and of the keeping qualities in (1) natural storage, (2) ice storage, and (3) chemical cold storage of a large number of varieties of apples. The work is based on experiments extending through several years at the station in storing station-grown apples in a storage fruit house without artificial refrigeration, on the extensive experience of practical men who have handled fruit for years both in cold storage and in ordinary fruit warehouses, and on cooperative tests with this Department in the storage of apples in chemical cold storage. A summary of the results secured in the latter case has already appeared in a bulletin of this Department (E. S. R., 15, p. 581).

In the experiments at the station the fruit was picked in each case when it had reached suitable condition, and was placed at once in a frame fruit storage house. This house was built with double walls with a partition between. The space between the partition and outer wall was filled with sawdust, while that between the partition and inner wall was kept a dead air space. The temperature of the storage room was regulated, so far as possible, by opening and closing the windows according to outside conditions. A table is given showing the fluctuations in temperature in the storage room in different months during the years 1896–1898, inclusive.

Under those conditions the average life of the different varieties fell as follows: In October—Gracie, Keswick, Parry, and Strode; first half of November—English Pippin, Alexander, Pound Sweet, Chenango, Pomona, and Stump; last half of November—Boskoop, Elgin, Pumpkin Russet, Jersey Sweet, Krimtartar, Haskell, and Longfield; first half of December—Ohio Pippin, Heidorn, Gravenstein, Longworth, and Tufts; last half of December—Haas, Ostrakoff, St. Lawrence, Tobias, Washington Strawberry, Romna, and Ginnie; first half of January—Admirable, Tobias Pippin, Magog, Aucuba, Gideon, and Disharoon; last half of January—Jefferis, McMahon, Stanard, Twenty Ounce, Blenheim, Mother, Wolf River, Fameuse, Crotts, Henniker, Jewett Red, and McIntosh; first half of February—Pomme Grise, Clarke, Victoria, Hurlbut, Kalkidon, Rhodes, Pumpkin Sweet, Barbel, Wealthy, Peter, Jacobs Sweet, Flory, and Fall Pippin; last half of February—Milligen, Pewaukee, Northern Spy, Falix, Brownlee, Greenville, Maiden Blush, Etowah, Cogswell, Grimes, Fall Wine, Landsberg, Jonathan Buler, Celestia, Dickinson, and Borsdorf; first half of March—Sharp, Peach, Hubbardston, Smith Cider, Milden, Tompkins King, Duke of Devonshire, Reinette Pippin, Marigold, Yellow Bellflower, Tolman Sweet, Buckingham, Northwestern Greening, Swenker, Melon, Domine, Dumelow, Rambo, Canada Baldwin, and Ornament; last half of March—Canada Reinette, Esopus Spitzenburg, Farris, Monmouth, Moon, Scott, Red Russet, Golden Russet, Golden Medal, Peck Pleasant, Sutton, Coon, Rhode Island Greening, Washington Royal, Ronk, and Wallace Howard; first half of April—White Pippin, Kansas Greening, Menagère, Holland, Mann, Jonathan, Olive, Swaar, Caux, White Doctor, Ewalt, Salome, Streaked Pippin, Arkansas, Duncan, Kittageskee, and Wallbridge; last half of April—Moore Sweet, Lankford, Yellow Forest, Newtown Spitzenburg, Occident, Ontario, Fallawater, Roxbury, Rome, Lady Sweet, and Vanhoy; first half of May—Kansas Keeper, Gideon Sweet, Cooper Market, Lawver, Chase, Wagener, York Imperial, Newman, Texas, Large Lady, and Baldwin; last half of May—Jones, Edwards, Stark, Kirtland, Ralls, Winesap, Ben Davis, Zurdel, and Nelson; first half of June—Green Newtown, Pifer, Andrews, and Red Canada. The average life of Schodack extended to July 18.

A summary of the experience of practical men on the keeping qualities of apples, as given by the authors, contains the following suggestions: Overgrown fruit does not keep as well as fruit of medium size. Thick-skinned varieties generally keep better than thin-skinned ones. Colored apples keep best if picked when well colored but still firm. With Rhode Island Greening in cold storage, however, the fruit

appears to keep better if picked while still very green and hard. In common storage the general rule holds. Rough handling of the fruit in the barrels and, of course, at any time previous to barreling, is very injurious. Northern Spy is one of the easiest to bruise, while Tolman Sweet and Yellow Bellflower are both very sensitive to rough handling. Only No. 1 fruit should be stored.

The fruit from trees grown in sod attains a higher color and keeps better than when the trees are given clean cultivation. Baldwins, however, grown on sandy or gravelly soil ripen earlier and have a higher color than when grown on clay soil, yet do not keep so well. Fungi on fruit affects its keeping quality injuriously. Affected fruit keeps best in a cold, dry atmosphere; clean fruit, however, keeps best with considerable moisture in the air. With practically all varieties the fruit keeps best if put into cold storage as soon as picked. Hubbardston may color up better if allowed to lie on straw on the ground 2 or 3 weeks. It is considered that while this practice may be desirable with some varieties which soon go into consumption, it injures the keeping quality.

Generally speaking, apples keep much better if the month of October is cool than if warm; and better after a dry season than a wet one. If the season is such that the fruit does not color up well, the result is the same as when the fruit is picked too green. Fruit which ripens unevenly on the trees should be given 2 or more pickings. Cold storage does not lengthen the life of all varieties over common storage to an equal degree. Thus, the season of Fallawater and Grimes in cellar storage, according to one handler, is January; but the season of Fallawater in chemical cold storage is May, a gain of 4 months, while the season of Grimes in chemical cold storage is February, a gain of but 1 month.

"As to the difference in season of varieties in cellar and in chemical cold storage, Howes makes this uniformly 60 days, i. e., 2 months for all varieties. Newhall makes it 1 month for 5 (early fall) varieties, 2 months for 19 varieties, 3 months for 23 varieties, 4 months for 8 varieties, and 5 months for Northwestern Greening. Graham makes this difference variously from $\frac{5}{6}$ month to 3 months. Hart makes this difference 2 months in a large majority of cases, with extremes of 1 and 4 months. . . .

"As to the relative efficiency of cellar and ice storage as applied to different varieties, Newhall reports that the season of 19 varieties is prolonged by ice storage 1 month beyond their season in cellar storage, 28 varieties, 2 months; 8 varieties, 3 months; and 2 varieties, 4 months. Graham gives the prolongation of season as from $\frac{1}{3}$ month to $2\frac{1}{2}$ months for the different varieties. Hart reports this difference as 1 month for 7 out of 9 varieties.

"As to the relative efficiency of storage under ice and of chemical cold storage, Newhall assigns the same season in either storage to 14 varieties. In the case of 40 varieties Newhall finds that chemical cold storage lengthens the season by 1 month as compared with cold storage under ice, and in the case of 2 varieties the season is lengthened 2 months. Hart reports 7 varieties as keeping 1 month longer in chemical than in ice storage. Graham assigns to one-half of the varieties he reports on a lengthening of the season by $\frac{1}{2}$ month in chemical storage, but in other cases this difference varies from $\frac{1}{3}$ month to $1\frac{1}{2}$ months.

"Shafer estimates the life of fruit in chemical cold storage as 60 days longer than the same varieties under ice, though in very cool seasons, such as that of 1903, there is, he says, hardly any difference in the keeping quality of the fruit in the two storages."

Tables are given showing in detail the seasons of certain varieties of apples in chemical cold storage, ice storage, and cellar storage, as given by the authorities noted in the above paragraphs.

The general principle which appears to hold in the storage of apples is that "varieties that keep long and go down slowly are held at about 31 to 32° F., while early

ripening varieties and those that do not keep so well are held 1 or 2 degrees higher, that is, at 33 to 34°. . . . The early apple, when held at a low temperature, loses in quality and when it comes out of storage it goes down quicker than if held at the higher temperature. Moreover, some fruit as, for instance, that of the ordinary Twenty Ounce freezes at a higher temperature than does other fruit like the ordinary Baldwin, and for this reason aside from others must be held higher."

Very large specimens of a variety which, as before noted, do not keep as well as medium-sized specimens, are held one degree higher in cold storage by some handlers. Others hold all sizes of the same variety at the same temperature. A table is given which shows in detail the temperatures at which different varieties of apples are held in cold storage by 5 different commercial fruit handlers.

Lists are given of the varieties of apples which are comparatively little affected in keeping quality by differences of season, of varieties liable to scald in storage, varieties especially liable to lose in quality in going down in cold storage, varieties liable to lose in color or to lack improvement in color when kept in cold storage, varieties which lose in firmness in going down in cold storage, varieties liable to become bitter in skin in going down in cold storage, varieties liable to shrivel in going down in storage, varieties liable to become mealy in going down in storage, varieties liable to burst in storage before decaying, varieties which go down gradually and varieties which go down quickly in storage, and the heat endurance of varieties after being picked and before being placed in storage.

The bulletin closes with a final summary for each of 205 varieties of apples, in which are included the results of tests of the keeping quality of apples in natural temperature storage at the station for the seasons 1895–6 to 1898–9, the keeping quality in cold storage as determined in cooperative tests with this Department, and the keeping quality as reported by cold-storage men.

Native plums (*Wisconsin Sta. Rpt. 1903, pp. 354–359*).—This is a summary of the following articles, previously published by the station: The Culture of Native Plums in the Northwest, by E. S. Goff (E. S. R., 10, p. 45), and Native Plums, by E. S. Goff (E. S. R., 13, p. 246).

Observations on the fertilization of peach orchards, E. H. JENKINS (*Connecticut State Sta. Rpt. 1903, pt. 5, pp. 428–431*).—The experiment here reported, on the value of different fertilizers for peaches, was begun in 1896 and is still under way. The general plan and results secured in the experiment up to 1902 have been previously recorded in detail and need not again be noted (E. S. R., 15, p. 475). In the present account the yields secured in 1903 on the different plats are added to the earlier records but conclusions are reserved for the future.

Citrus fruits and their culture, H. H. HUME (*Jacksonville, Fla.: The H. & W. B. Drew Co., 1904, pp. XXII+597, pls. 36, figs. 124*).—This is a very complete treatise on citrus fruits and their culture. It covers the various citrus regions of the United States, but deals more especially with the industry in Florida.

The various parts into which the book is divided treat of the botany, history, and varieties of oranges, lemons, pomelos, kumquats, citrons, and limes; the culture of each of these classes of fruits; diseases and insects affecting, etc. A bibliography of about 40 references is included, and in the appendix a list is given of the members in different cities belonging to the National League of Commission Merchants. Each cultural phase, from the selection and budding of the stocks to the packing and shipment of the fruit, is discussed exhaustively and in addition to the usual subjects treated, chapters are given on pot culture, originating new varieties, judging citrus fruits, frost protection, etc.

In the preparation of the book extensive account has been taken of the citrus literature of the experiment stations, more particularly that of the California and Florida stations, and of the experiences of citrus growers in those States. The book

is a valuable addition to the citrus literature of the country, and should prove especially helpful to citrus-fruit growers in the southern States.

Cultivation of citrus groves, H. H. HUME (*Florida Sta. Bul. 69, pp. 29, figs. 2*).—A discussion of the principles to be observed in the cultivation of citrus fruits in Florida, with accounts by 8 successful Florida citrus-fruit growers of their individual methods of culture. The conservation of soil moisture by cultivation was brought out by analyzing soil from cultivated and uncultivated orchards. The uncultivated soil contained 4.17 per cent of moisture, and the cultivated soil 6.97 per cent. In other words, the cultivated soil was 66.5 per cent more moist than the uncultivated.

Cooperative experiments with small fruits, H. L. HUTT (*Ontario Agr. and Expt. Union Rpt. 1903, pp. 29–36*).—The cooperative testing of small fruits has been carried on for 10 years, and at present involves 1,297 experimenters. A copy is given of a circular which contains information regarding the varieties to be tested, the methods to be employed, and the special points to be observed by the experimenters in different parts of Canada.

Varieties of strawberries and raspberries, W. J. GREEN and C. W. WAID (*Ohio Sta. Bul. 146, pp. 29–40, figs. 15*).—Brief notes are given on each of the 74 varieties of strawberries and 10 varieties of raspberries grown at the station. Of the strawberries, the most satisfactory early varieties were August Luther, Cameron Early, Excelsior, Johnson Early, Thompson Early. Of the midseason varieties special mention is made of Kittie Rice, Marie, Miller, Parson Beauty, Sample, Senator Dunlap, Haverland, Warfield, Pocomoke, Greenville. Well tested or promising late varieties are Yant, Brandywine, Gandy, Lester Lovett, Robbie, Nettie.

For the home garden the following are named because of excellent flavor: August Luther, Marshall, Brunette, Kittie Rice, Nettie, Robbie, Corsican, Granville, Yant. The following prolific varieties are especially suited to near market: August Luther, Kittie Rice, Marie, Parson Beauty, Sample, Haverland. For long shipment and for canning the following are suitable: Warfield, Senator Dunlap, Granville, Gandy, Cardinal, Excelsior, Lyon, Marie, Parson Beauty.

Grape growing for home use, J. C. WHITTEN (*Missouri State Bd. Agr. Mo. Bul., 4 (1904), No. 1, pp. 5–12, figs. 2*).—Popular directions for the culture of grapes in Missouri, with some statistics taken from the United States Census relative to the grape and wine industry in Missouri.

On the failing of vineyards at Montagu, C. MAYER (*Agr. Jour. Cape Good Hope, 24 (1904), No. 6, pp. 695, 696*).—The author visited Montagu at the request of the public to investigate the cause of the failure and death of large numbers of vineyards. The main cause of death was found to be due to the decay of the principal roots brought about by excessive irrigation extending over a long period of years which compacted the soil at a depth of about 2½ to 3 ft. to an excessive degree.

Foreign import tariffs on fruits and nuts, 1903, F. H. HITCHCOCK (*U. S. Dept. Agr., Division of Foreign Markets Bul. 36, pp. 69*).—The duties levied by foreign countries on fruits and nuts are herein arranged in tabular form, the different countries being considered alphabetically.

Pecan culture for western Texas, E. E. RISIEN (*San Saba, Texas: Author, 1904, pp. 55, pls. 9*).—Special attention is given in this small treatise on pecan culture to the propagation of improved varieties on old stock by budding. In addition, the growing of seedling trees and the transplanting and management in the orchard of pecans are fully described, and many useful hints given on the peculiarities of pecans and on varieties, crossing, enemies, etc.

The commercial value, etc., of the seeds of the Para rubber tree (*Agr. Bul. Straits and Federated Malay States, 3 (1904), No. 2, pp. 43–48*).—Seeds of the Para rubber tree (*Hevea brasiliensis*) were sent to the Imperial Institute, London, England, for examination as to their constituents and commercial uses.

The report includes the results of the examination of the whole seed, the decorticated seed, and of meal made from the seed. It appears from the analyses given that the kernels constitute about 50 per cent by weight of the whole seed. The sample examined contained 42.3 per cent of oil. The husk and kernel (whole seed) ground together yielded 20 per cent of oil. "The oil obtained from the kernels alone is clear, of a light yellow color, and has an odor somewhat resembling that of linseed oil. It belongs to the class of drying oils, and yields a clear, transparent film when allowed to dry by exposure to air. The husks contain a solid fat, which has a high saponification number and a low iodin value, but since the amount of this solid fat in the husks is very small it makes but little difference to the properties of the oil obtained from kernel and husks ground together."

The oil extracted from the rubber-seed meal was solid instead of liquid, as in the case of the seeds, owing to certain decomposition changes which take place after the seed is crushed and caused by the action of a hydrolytic enzym contained in the seed. The analysis of the meal is as follows: Moisture 9.1, ash 3.53, fiber 3.4, oil 36.1, proteids 18.2, and carbohydrates 29.67 per cent. The meal examined contained a considerable quantity of free fatty acid which would make it unfit for fodder purposes, or for the expression of oil; but it is thought probable that if the oil were expressed from the decorticated seed the residual cake could be used as a feeding material, having a composition very similar to some of the oil-cake feeds now on the market.

Commercial brokers report that the oil could probably be used as a substitute for linseed oil, and would be worth about £20 per ton; while the decorticated seed would be worth £10 to £12 per ton. Para rubber cake would be worth £5.15 to £6.15 per ton if prepared as suggested above.

Preparing "Para rubber" in Ceylon, F. J. HOLLOWAY (*Agr. Bul. Straits and Federated Malay States, 2 (1903), No. 3, pp. 108–110*).—From the author's account it appears that the rubber prepared on the Kepitigalla Estate in Ceylon brings the highest price of any in the world. A full description is given of the methods of tapping, collecting, and coagulating employed.

The latex is strained into shallow tin pans about 7 in. square by 2 in. deep, and left over night. By morning the rubber is coagulated without the use of any chemicals and most of the water separated from the pure rubber. The characteristic features appear to be the straining of the latex so as to remove every particle of dirt, and the rolling of the chunks of rubber obtained into flat, thin sheets about 8 in. square and $\frac{3}{8}$ in. thick. The thinness of the sheets permits the buyer to see at once that they are free from dirt, hence the higher price.

Rubber-tapping experiments in the Botanic Gardens (*Agr. Bul. Straits and Federated Malay States, 2 (1903), Nos. 2, pp. 44–47; 3, pp. 111–113; 8, pp. 264–266*).—Part of the work here reported has been previously noted (E. S. R., 15, p. 479). Continuing the observations it has been found that, in tapping, all sides of the trunk, practically, flow with equal freedom. Dry weather materially decreases the flow of latex, and in periods of drought it is believed that tapping should cease altogether.

The flow of latex has been found more copious and thicker and, therefore, to produce more rubber if tapped from the base of the tree to about 4 ft. high on the trunk than when tapped higher. The assertion, sometimes made, that by reopening old wounds a larger flow of latex may be secured was not found true in these experiments. The greatly diminished yield obtained when trees were tapped when in bloom, amounting to nearly 50 per cent, leads to the conclusion that on no account should rubber trees be tapped when in flower.

Considerable tabular matter is given, which shows the yield of rubber obtained from trees of various sizes and at different dates.

Rubber from Willughbeia edulis and Urceola esculenta in Burma, W. R. DUNSTAN, S. CARR, and J. W. LEATHER (*Agr. Ledger, 1903, No. 10 (Veg. Prod. Ser., No. 76), pp. 233–238*).—Data are given on the flow of latex from these plants, the

chemical composition of the rubber made from them, and the commercial possibilities of rubber making in connection with them.

Latex of *Willughbeia edulis* proved of a very resinous nature, exhibiting the physical properties neither of gutta-percha nor rubber. That portion which was insoluble in acetone but dissolved by chloroform did not resemble ordinary caoutchouc in appearance or properties, being soft, sticky, and inelastic. It is believed to have little or no commercial value from the standpoint of rubber production. The rubber obtained from *Urceola esculenta* was of fair quality, comparing favorably with that known in the trade as "Tonquin." Extensive tapping experiments, however, showed that only a very small amount of latex could be secured from each creeper, and that the cost of tapping and collecting was so great as to prohibit rubber making from this plant as a commercial industry.

The book of town and window gardening, MRS. F. A. BARDSWELL (*London and New York: John Lane, 1903, pp. 105, pls. 23*).—This book is intended to meet the wants of city and town people who may have but little yard space to give to ornamental plants, or who may desire to grow plants in window boxes. Suggestions are given for the culture of plants on balconies, roofs, in back yards, in small suburban gardens, and on walls.

This is the nineteenth volume in the series of Handbooks of Practical Gardening, edited by H. Roberts, and like most of the preceding, treats the subject from the English standpoint. Those engaged in the encouragement of gardening among the city poor may find useful suggestions in it.

Directions for making window gardens, W. W. TRACY (*U. S. Dept. Agr., Bureau of Plant Industry Pamphlet, Mar. 28, 1904, pp. 8, figs. 8*).—Popular directions for the planting and care of window gardens.

The school garden, L. C. CORBETT (*U. S. Dept. Agr., Bureau of Plant Industry Pamphlet, Feb. 25, 1904, pp. 6, dgms. 2*).—Popular directions for laying out and planting small school gardens.

FORESTRY.

Manual of forestry. II, Sylviculture, W. SCHLICH (*London: Bradbury, Agnew, & Co., Ltd., 1904, 3. ed. rev., pp. VIII+393, figs. 87*).—This volume treats of the formation, regeneration, and care of forests or woods in such a manner as to realize for the proprietor the greatest returns for his investments. The subjects considered are: The foundations of sylviculture, the formation and regeneration of woods, care of woods, and notes on some forest trees.

Under the heading, the foundations of sylviculture, the author considers the relation of climate, soil, and other local factors to forest vegetation, the development of forest trees, character and composition of woods, sylvicultural systems, and methods of treatment. Under the second, the preliminary work for the formation and regeneration of woods, care, etc., the preliminary work necessary for establishing forests is discussed, after which, directions are given for the artificial formation and natural regeneration, formation of mixed woods, and suggestions for making a choice of the different methods described.

Under the topic of care of woods, suggestions are given for the protection of woods while the trees are young, the subsequent treatment to prevent crowding, and for the production of large timber. The volume concludes with sylvicultural notes of 21 species of British forest trees, in which descriptions are given of their characteristics, value for timber, etc.

Effects of weather on tree growth, C. E. HALL (*Trans. and Proc. Bot. Soc. Edinburgh, 22 (1901), pt. 1, pp. 71–88*).—In continuation of previous notes (E. S. R., 12, p. 1048) a description is given of the effects of weather on tree growth. In the previous paper the conclusion arrived at was that rainfall was the most essential factor in the growth of trees.

In the present paper attempts are made to analyze the data published previously, and comparisons are drawn between the growth of different species of trees and the rainfall and temperature. In general it appears that a season of heavy rainfall is accompanied by good growth, and where the rainfall is slight relatively little tree growth is made. From the tables given it appears that rainfall, at least under the conditions of the author's observations, is the most important, temperature and sunshine being accessories.

The effects of a hailstorm on growing timber, H. C. SAMPSON (*Trans. and Proc. Bot. Soc. Edinburgh, 22 (1902), pt. 2, pp. 254–257*).—An account is given of the effect of a heavy hailstorm on various timber crops. The storm occurred in June when the trees were in full leaf and through the loss of leaves, destruction of twigs, etc., there must have been a reduction of the year's growth. Wounds caused by the hailstones were observed on the stems of trees where the young bark was still smooth and no damage was observed on the bark of branches more than 2 in. in diameter.

The coniferous trees seemed to have suffered the least, and wounds formed on the stems were soon covered by an exudation of resin. Among the coniferous trees larch appeared to have suffered most. Scotch pine was damaged to a considerable extent, while spruce seemed the least affected of any. The proportion of the amount of injury to broad-leaved trees was in the order of willows and poplars, ash, sycamore, oak, alder, beech, and birch.

The damage done in the injury to the deciduous trees was reported in the following order, those first mentioned healing quickest: Mountain ash, beech, alder, ash, birch, sycamore, oak, poplars, and willows.

On the influence of various fertilizers on pine and spruce plantings, T. CANNELIN and L. STENBÄCK (*Landtbr. Styr. Meddel., 1903, No. 44, pp. 159–161*).

Forestry, F. W. RANE (*New Hampshire Sta. Bul. 106, pp. 27–43, figs. 9*).—This is a popular bulletin giving an account of forests and forest management, and how to convert waste lands into forests adapted to different uses. The suggestions are designed for the reforesting of worn-out fields, natural pastures, burned-over wood lots, sprout or brush lands, sandy barrens, and low, wet lands.

Advancement in American forestry, E. E. FAVILLE (*Proc. Iowa Park and Forestry Assoc., 3 (1903), pp. 37–42*).—A brief review is given of the forestry situation as shown by census reports, and attention called to some of the conditions as shown by the forests of Michigan, Wisconsin, and Minnesota. The more recent legislation regarding forest reserves, and the work of the Bureau of Forestry of this Department are outlined.

The future of Federal forest reservations, E. A. BOWERS (*Forestry and Irrig., 10 (1904), No. 3, pp. 131–135*).—An outline is given indicating future lines of development of the forest reservations, among the most important of which the author believes will be their educational value. These reservations, scattered through a wide range of latitude and longitude and dealing with widely varying conditions, must furnish accumulating experience and knowledge of forestry that will be put to future use.

A forest policy for Massachusetts, B. E. FERNOW (*Forestry Quart., 2 (1904), No. 2, pp. 49–74*).—In a lecture delivered before the State Board of Agriculture of Massachusetts a review was given of the forestry condition of Massachusetts and an attempt was made to outline a forest policy for the improvement of the conditions existing in that State.

Among the points advocated, as given in the summary of the lecture, were the improvement of the forest-fire laws, the appointment of a State forester, encouragement by financial aid of associations and educational agencies concerned in forestry, the acquisition by the State for forest reserves of stump, brush, and waste lands, the encouragement of towns to acquire town forests, and the encouragement of private

owners to improve their wood lots and plant waste places by furnishing expert advice, plant material at cost, and by the passage of a just tax law.

The Michigan State forest reservation (*Forestry Quart., 2 (1904), No. 2, pp. 75, 76*).—A brief description is given of the forest reserve which has been established in Michigan according to plans provided by the State Forestry Commission and the Bureau of Forestry. This territory covers 17 sections of land, the nature of which is described and the species representing the present tree growth are enumerated.

The south part of Pike's Peak Forest Reserve, J. C. BLUMER (*Forestry and Irrig., 10 (1904), No. 4, pp. 169–174, figs. 3*).—A description is given of a portion of the Pike's Peak Forest Reserve situated in the southern part of Colorado, in which an account is given of the fire conditions, water conservation, and mountain timber. The principal species of trees are the Engelmann spruce, several species of pine, fir, etc. The distribution, rate of growth, and relative value of the different species are indicated.

Natural forest extension, C. W. YODER (*Forestry and Irrig., 10 (1904), No. 4, pp. 184–186*).—An account is given of the tendency of forest trees to encroach upon the prairie of northeastern Kansas. The author traces the steady encroachment of timber belts along various creeks, particular attention being paid to Pony Creek in the western part of Brown County, Kansas.

The forest conditions along this creek are not unlike those found along a number of other streams in the same region and personal observations have extended them along the Missouri River westward. In passing westward there is a gradual restriction in the forest areas and a decrease in the number of species, but the prevalence of young trees along ravines and smaller streams indicates a recent extension of forest area.

The planting of white pine in New England, H. B. KEMPTON (*U. S. Dept. Agr., Bureau of Forestry Bul. 45, pp. 40, pls. 13, figs. 2*).—According to the author, white pine may be advantageously used for planting on watersheds, sand barrens, and seaside dunes, on bare lands and worn-out pastures, on cut-over lands, and on wood lots throughout the United States from Maine to Dakota and south to the Missouri and Ohio rivers, and along the mountains to Alabama and Georgia. A study of the white pine in New England showed the practicability of its planting, not only by States and corporations but by the private landowner as well.

The bulletin reports the results of investigations of 12 artificial plantations, amounting to about 2,500 acres. These embrace pure plantings of white pine and white pine with various mixtures. Measurements were made of 98,995 trees, varying in age from 11 to 48 years. These were made to determine the rate of annual growth for each year from the starting stage. The different plantations are described in detail. The different mixtures used are discussed and the relative value of European larch, oaks, chestnut, Scotch pine, red pine, Norway spruce, and sugar maple for planting with white pine is shown. Directions are given for starting a white pine plantation, including notes on the collecting and storing of the seed, preparation of the seed bed, sowing, and shading, the preparation of the plantation, transplanting, and treatment after planting.

From the figures presented it appears that the first profitable lumbering may be practiced between 35 and 45 years after planting. An estimate is given of the cost and profit of an average 60-acre plantation of white pine on waste pasture land in New England, valuing the land at $4 per acre, the crop to be cut at the end of 40 years from the formation of the seed bed. Based upon present prices and deducting all expenses, it is calculated that the return would be equivalent to $1.15 per acre annually in addition to 4 per cent compound interest on the money invested.

Tree planting on our northern prairies, W. A. BURNAP (*Proc. Iowa Park and Forestry Assoc., 3 (1903), pp. 42–46*).—In a brief account the author gives the results of about 50 years' observations on the prairie region of Iowa during which time the

treeless plain, through the agencies of planting and protection, has been transformed into an apparently wooded region.

Why is tree planting a failure? T. H. DOUGLAS (*Proc. Iowa Park and Forestry Assoc., 3 (1903), pp. 27–31*).—According to the author the reasons for failure in tree planting are unsuitable selection of trees, careless planting, and neglect after planting. In order to avoid failure attention is called to some of the necessary procedures to be followed in the selection, planting, and care of trees.

Present condition of Iowa forests, L. H. PAMMEL (*Proc. Iowa Park and Forestry Assoc., 3 (1903), pp. 53–75*).—A review is given of the previous forest condition of Iowa, contrasting it with the conditions as they exist at the present time.

On account of the importance of tree planting in the State the author suggests a number of species which have proved of value for planting in parts if not all of the State. This list includes white, Austrian, and Black Hills pine, white and Colorado spruce, Douglas fir, hemlock, larch, Eastern red cedar and Western cedar, cottonwood, soft and black maple, box elder, green ash, black walnut, butternut, American elm, bur oak, and honey locust.

Extended notes are given on the value, from the tree planter's standpoint, of the cottonwood, soft maple, walnut, green ash, white and Austrian pine, and the red cedar.

The phenology of our trees, CHARLOTTE M. KING (*Proc. Iowa Park and Forestry Assoc., 3 (1903), pp. 47–53, dgm. 1*).—The writer has brought together scattered records pertaining to the trees of Iowa, the data being a consolidation of records of Iowa trees and shrubs so far as kept to the present time, together with temperature averages which are believed necessary to the proper understanding of the variations shown in the different tables.

Cooperative experiments in forestry, R. D. CRAIG (*Ontario Agr. and Expt. Union Rpt. 1903, pp. 36–40*).—An account is given of efforts that have been made by the author and others to secure cooperative experiments between the Canadian government and various individuals and societies for reforesting portions of that country.

The management and planting of British woodlands, C. E. CURTIS (*Jour. Roy. Agr. Soc. England, 64 (1903), pp. 16–49, figs. 6*).—A review is given of the condition of British woodlands, which are said to be in a very unsatisfactory state, and suggestions made as to how their present condition might be profitably improved.

Exotic conifers in Britain, W. SOMERVILLE (*Jour. Bd. Agr. [London], 10 (1903), No. 3, pp. 319–346*).—A translation is given of a paper contributed to the Congress of Forestry Experimental Stations, held at Vienna September, 1903, in which the distribution, forestry characteristics, and growth of a considerable number of exotic species of conifers, most of which are of American origin, are described.

The conversion of home-grown timber, R. ANDERSON (*Jour. Roy. Agr. Soc. England, 64 (1903), pp. 50–75, figs. 4*).—According to the author the competition of foreign-sawn timber of standard size at low prices has almost destroyed the demand for home grown. For other uses the demand has been well maintained. The value of timber from different species of trees for special uses is pointed out and suggestions given for the conversion of timber and for the utilization of waste and by-products.

The Philippine forestry service, W. KLEMME (*Forestry and Irrig., 10 (1904), No. 4, pp. 158–162, figs. 4*).—Notes are given on the life and work of the American foresters in the Philippines, describing the climatic conditions under which the work is carried on, the methods of estimating the output, and determining the trees for cutting. According to the author the increased importance of this work is shown by the revenues derived through the Forestry Bureau, which in 1900–1901 amounted to $199,373; in 1901–2, $348,073; and 1902–3, $527,414.

Report on the forest administration of the Central Provinces, 1902–3, B. ROBERTSON, H. A. HOGHTON, E. G. CHESTER, and E. E. FERNANDEZ (*Forest Dept., Cen-*

tral Provinces, India, Rpt. 1902–3, pp. 184).—A report is given of the forest administration of the Northern, Southern, and Berar circles of forest administration of the Central Provinces of India. This includes a classification of forest areas, a report on survey and demarcation of the forests, a progress report on the scientific working of the forests, the operations carried on during the year with special reference to forest products, the financial results, etc.

The total area of forests under government control in these regions amounts to 22,869 sq. miles, of which nearly one-third is systematically protected against fire, grazing, etc. Investigations are being conducted in which certain areas which have small value as forests are to be systematically burned over each year in order to obtain information on the subject of the relative yield of fodder and grazing on burned and unburned areas. Other portions of the forests which are of little value for forest purposes are to be transferred to grazing areas, and grazing in the more valuable forests is to be restricted in order to permit natural reproduction and growth of seedlings.

Progress report of forest administration in the Madras Presidency (*Forest Dept., Madras Presidency, India, Rpt. 1902–3, pp. 163*).—A progress report is given of the forestry administration in the Madras Presidency for the year ending June 30, 1903. During this period a slight reduction in the forest area is noted, the reserved forests and the reserved lands now amounting to 19,455 sq. miles. The results of preliminary investigations in the different districts in which the boundaries of the various forests and reservations were examined are reported upon, together with forest surveys, management of State forests, etc.

Progress report of the forest administration in the lower provinces of Bengal, A. L. McIntire (*Forest Dept., Bengal, India, Rpt. 1902–3, pp. 60*).—This report, which covers the year 1902–3, gives statements regarding the operations in the reserved forest area in which it appears that at present 8.92 per cent of the area of the provinces is now entered on the books of the forest department. Statements are given regarding the areas in the forest settlement, boundary inspections, surveys, management of State forests, including working plans, and the protection of forests from fire, grazing, etc.

Annual report of the conservator of forests, 1902, T. R. Sim (*Natal Agr. Dept. Rpt. 1902, pp. 69–92*).—A description is given of the forests of Natal as observed by the author in the short period that intervened between his appointment as forester and the time for preparation of his report, and a plan for the conservation of the forests is outlined.

The chemistry of the forest, J. B. Weems (*Proc. Iowa Park and Forestry Assoc., 3 (1903), pp. 31–36*).—The author describes the various chemical processes connected with forest growth, beginning with the planting of the seed in the soil. The results of analyses of various commercial parts of trees are given, and attention called to some of the principal products derived from trees aside from lumber, timber, etc.

Treatment designed to add to the durability of posts, F. W. Card and A. E. Stene (*Rhode Island Sta. Rpt. 1903, pp. 226–229, pls. 2*).—A description is given of the preliminary treatment given posts to test the relative efficiency of the different methods for prolonging their durability.

The posts used were green chestnut, and when planted half of the posts were set top end down and the other half bottom end down. In addition one row was set without any treatment. The second row had the ends set in the ground charred by placing them over fire until thoroughly blackened and somewhat burned. The posts of the third row were painted with coal tar. Those of the fourth row were painted in the same manner with hot pine tar. The posts of the fifth row were treated with lime by being set in pits, the bottoms of which were filled with fresh lime on which the posts were set, the spaces being filled with the lime and water

added to cause it to slack. The posts in the sixth row were soaked over night in a solution of iron sulphate and then dipped in limewater, while those of the seventh row were treated with carbolineum, a proprietary wood preservative.

The results of the treatment will be reported from time to time.

SEEDS—WEEDS.

Tests of the vitality of vegetable seeds, E. H. JENKINS (*Connecticut State Sta. Rpt. 1903, pt. 5, pp. 432–439*).—A report is given of the tests of 201 samples of field and garden seeds, which were made during the year covered by this report, and are in continuation of those previously reported (E. S. R., 15, p. 482). The average maximum and minimum vitality of all the different lots of seed are reported in tabular form, after which notes are given on the vitality of onion seed as affected by age. A comparison is given of the vitality of crops of Connecticut grown onion seeds in the years 1894 to 1903, and the sprouting capacity of different varieties of onion seed.

Long distance transportation of seeds, J. C. HARVEY (*Agr. Bul. Straits and Federated Malay States, 2 (1903), No. 1, pp. 5, 6*).—An account is given of a method of packing seeds of *Castilloa elastica* in which their vitality was retained for more than 100 days.

Fresh seeds were dried and cured for 5 days in the shade, after which they were packed in 6 and 8 oz. tins in powdered charcoal. To every pint of pulverized charcoal was added 1 tablespoonful of water, the charcoal being thoroughly mixed by shaking it through a sieve. The seeds were then packed in tins, adding charcoal so that all the interstices were thoroughly filled, after which the charcoal was heaped up and the top of the can pressed down so as to prevent any shaking. The seed were shipped from Vera Cruz, Mexico, to California, and at the expiration of 115 days were returned and sown, with the result that 60 per cent of the young seedlings developed.

In a similar way seeds of the jack or breadfruit nut (*Artocarpus integrifolia*) were shipped from Burma, 80 per cent of the seeds producing plants.

The Macdonald-Robertson Seed Growers' Association, G. H. CLARK (*Ontario Agr. and Expt. Union Rpt. 1903, pp. 55–58*).—A description is given of the aims and methods of the above seed growers' association, which was organized largely for the improvement of seeds of agricultural plants.

Seed control in Cape Colony, E. A. NOBBS (*Agr. Jour. Cape Good Hope, 24 (1904), No. 5, pp. 617–621*).—A description is given of the facilities provided by the Department of Agriculture of Cape Colony for the systematic analyses of seed. Forms are given of application blanks for testing seed samples, a form of report, and directions for taking samples, charges for making the analyses, etc.

The methods of seed analysis, E. A. NOBBS (*Agr. Jour. Cape Good Hope, 24 (1904), No. 3, pp. 354–361, figs. 4*).—A brief account is given of the methods of seed analysis and a description given of seed testing as carried on in a number of European and American laboratories. Direction is given for the drawing of samples, botanical examination, germination, tests, etc.

Annual report of the central seed-testing laboratory of Aynsome, J. S. REMINGTON (*Aynsome Agr. Sta., Grange-over-Sands, Cent. Seed-Testing Lab. Rpt. 1903, pp. 42*).—A report is given of the seed testing carried on at the central seed-testing laboratory for the period from September 1, 1902, to June 30, 1903, during which time 697 samples of seed were examined.

The rules followed at this station are modeled on those adopted by the German seed control stations and in the main have proved very satisfactory. A synopsis is given of the requirements for seed inspection and the principal investigations are briefly outlined.

The analysis of feeding cakes and meals has been begun by the station and will be reported upon in a separate publication. Detailed reports are given of the results of the different analyses of seeds, the most of which were grasses and leguminous forage plants.

The new seed control station at Vienna, T. VON WEINZIERL (*Ztschr. Landw. Versuchsw. Oesterr., 7 (1904), No. 5, pp. 391–403, pls. 14*).—An illustrated description is given of the new buildings of the seed control station of Vienna. Notes are also given on the establishment, personnel, and work of the station.

Weeds and their suppression, J. PERCIVAL (*Jour. Bd. Agr. [London], 10 (1904), No. 4, pp. 461–467*).—In a popular article the author calls attention to various methods by which weeds may become distributed, the effect they produce upon agricultural crops, and suggests a number of means for their eradication. These methods include the use of clean seed in sowing, deep plowing, and thorough cultivation where once established, the use of special fertilizers for curing the acidity of soils, etc., and for certain weeds special treatment with herbicides.

Equisetum palustre and its eradication, H. JUHLIN-DANNFELT (*K. Landt. Akad. Handl. och Tidskr., 42 (1903), No. 4, pp. 335–339*).

Weeds on Swedish moor plantations, R. TOLF (*Svenska Mosskulturför. Tidskr., 17 (1903), No. 6, pp. 428–440*).

DISEASES OF PLANTS.

Report of the vegetable pathologist, D. McALPINE (*Jour. Dept. Agr. Victoria, 2 (1903), No. 3, pp. 250–260*).—The material of this report is grouped under the following headings: Experiments, principal diseases of the year, publications, and miscellaneous notes.

Among the experiments reported upon was a test of various materials added to Bordeaux mixture and used for the prevention of diseases of apple and pear. Among those added to the mixture were sulphate of ammonia, sal-ammoniac, saltpeter, and common salt, with a slight difference in favor of common salt at the rate of 1 lb. to 40 gal. of water. There was practically no advantage noticed that could be attributed to the addition of the other chemicals. The copper-soda mixture in which washing soda is substituted for lime of Bordeaux mixture was tested and was found to not give the same adhesiveness as when Bordeaux mixture of the usual formula was used.

Notes are given on the bitter pit of apple, rust in wheat, variety tests of wheat, oats, etc., stinking smut experiments in which seed wheat was treated with a number of substances of which copper sulphate, formalin, and corrosive sublimate gave uniformly good results, etc.

Among the principal diseases reported upon are the early blight of potato, a disease of tubers to which the name "blister" is given, and a sclerotium disease of potatoes. The blister disease seemed to be due to the presence of immense numbers of nematodes. The early blight of potatoes is attributed to *Alternaria solani*, and the sclerotium disease to an imperfectly known fungus.

Brief notes are also given on a disease of cauliflower which arises in the seed bed, root rot of fruit trees, mold of wheat, and tobacco mold. The latter attacks the plants in the seed beds, and the best results so far obtained for the prevention of this disease have followed the treatment of the beds before sowing with a rather strong Bordeaux mixture.

Among the miscellaneous notes reported upon are the destruction of charlock or wild mustard by spraying with copper sulphate solution, the reputed poisonous nature of the black nightshade (*Solanum nigrum*), and notes on the destruction of mistletoe.

Annual report of the consulting botanist, W. CARRUTHERS (*Jour. Roy. Agr. Soc. England, 64 (1903), pp. 296–309, figs. 5*).—A report is given of the investigations

carried on by the consulting botanist for the year ending 1903. During this time 154 samples of seed were examined for their purity and germination and a considerable number of diseases of plants, weeds, and poisonous plants reported upon.

Among the plant diseases reported a description is given of a disease of turnips which has proven rather serious in parts of England. This disease was of fungus origin and it is believed to be due to *Phoma napo-brassicæ*, which was first described in 1893 (E. S. R., 6, p. 737). For the prevention of this disease the author suggests the removal and destruction of all affected roots, and on the assumption that the fungus reaches the root through the leaves the foliage should be sprayed with either a solution of copper sulphate or, what is probably better, a rather strong Bordeaux mixture. Miscellaneous notes are given on a number of other diseases.

Diseases of plants cultivated in Connecticut, G. P. CLINTON (*Connecticut State Sta. Rpt. 1903, pt. 4, pp. 279–370, pls. 21*).—The author describes the causes of plant diseases and discusses parasitic fungi of different kinds. Notes on the prevention of diseases, directions for the preparation of fungicides, and descriptions of various kinds of spraying apparatus are given. Following these, notes are given on some of the more specific diseases that have been noticed within the past 2 seasons, the arrangement being by an alphabetical list of the hosts.

Plant diseases in 1901–2, WEISS (*Vrtljschr. Bayer. Landw. Rat., 8 (1903), No. 4, pp. 640–668; Sup., pp. 733–763*).—The occurrence of various plant diseases and injuries due to parasitic organisms, physiological disturbances, and insect attacks are noted, and suggestions are offered for the protection of plants from injury. The notes are arranged according to the host plants.

Plant diseases in Denmark, 1902, E. ROSTRUP (*Tidsskr. Landbr. Planteavl, 10 (1904), pp. 361–379*).—A review is given of the more important diseases of plants observed during the period.

Letters on the diseases of plants, N. A. COBB (*Agr. Gaz. New South Wales, 15 (1904), No. 1, pp. 1–19, pls. 6, figs. 10*).—Notes are given on a number of diseases of plants, among them the brown rot of fruits due to *Monilia fructigena*, a cherry blight due to a Dematium-like fungus, various rusts and smuts of cereals, some diseases of citrus fruits, black spot of apple and pear, etc.

Some unusual fungus diseases in Iowa during the summer of 1903, L. H. PAMMEL (*Proc. Soc. Prom. Agr. Sci., 1904, pp. 144–156, pls. 2*).—Notes are given on a number of fungus diseases of economic plants which are either of quite recent occurrence within the State or which possess some unusual features.

A discussion is given of the relation between climatic conditions and fungus development in which it is shown that many fungus diseases are favored by a combination of climatic conditions while others do not seem to be affected. The downy mildew of the grape is said to be favored by moist, damp weather, while the powdery mildew is favored by drier weather with frequent dews. The mean temperature and precipitation at the Iowa Station are given for a number of years, and accompanying them are brief statements regarding the occurrence of a number of diseases.

Chlorosis of plants: Cause and prevention, A. DEMENTYEV (*Zhur. Opuitn. Agron. [Jour. Expt. Landw.], 4 (1903), No. 6, pp. 714–733*).—The author critically examined the various hypotheses regarding the cause of chlorosis, and from his observations concludes that in the majority of cases chlorosis is caused by parasites upon the roots of the plants. Beginning usually with the more minute divisions of the roots the parasites lay bare the ends of the vessels, interfering with the normal course of the absorption of the soil solutions.

The author believes that chlorosis develops as follows: Owing to the evaporation of water through the leaves and to the negative pressure thereby produced in the stem of tree-like plants, the salt solutions enter directly from the soil into the vessels of the roots which have been laid open by the parasites. These rise into the leaves where, through evaporation, they attain a high concentration. Under the influence

of the high concentration of these salts the stomata of the leaves close and the gas exchange stops. In consequence of the deficiency of oxygen and carbohydrates no new formation of chlorophyll takes place, while the chlorophyll previously formed is destroyed by the light.

A process thus takes place which is analogous to the turning yellow of the leaves in the fall. If the absorption of the salts by the plant takes place in the normal way no chlorosis is observed, because this absorption proceeds slowly, the plant being provided with appliances which enable it to prevent an excessive concentration of the salts in the leaves. When, on the contrary, the salts directly enter into the plant through the exposed vessels of the roots these appliances prove insufficient and do not function normally.

Experiments by the author showed that solutions moving in the direction of the least resistance first reach that part of the crown which corresponds to the respective root branch. Herein is the explanation of the fact that usually chlorosis appears not on the entire plant, but on certain of its parts corresponding to the injured branches of the roots. The circumstance of the rapid absorption of solutions through exposed vessels of the roots suggests to the author the proposition to utilize this phenomenon for artificial nutrition and watering of fruit trees as well as for combating the enemies of the latter.

Whenever plant parasites or insects are the causes of injuries it is rational, in the opinion of the author, to have recourse to the use of carbon disulphid, as is commonly used for phylloxera.—P. FIREMAN.

Heterœcious rust fungi, H. KLEBAHN (*Die Wirtswechselnden Rostpilze. Berlin: Borntræger Bros., 1904, pp. XXXVII+474; rev. in Nature* [*London*], *69* (*1904*), *No. 1800, pp. 601, 602*).—The author treats of the general aspect and discusses the subject of heterœcism in rust fungi, after which special descriptions are given of the various species in which this phenomenon has been recorded, the biology of each being treated in detail. The various headings of the chapters indicate the scope of the work.

After defining heterœcism and giving a history of the subject, a summary is given of the types of rust fungi involved. The means of distribution, germination, and infection of the various kinds of spores are described and various controverted points in the life history of the fungi are discussed. The author rejects Ericksson's mycoplasma theory (E. S. R., 10, p. 316) as accounting for the wintering and subsequent infection of the various host plants.

The specialization of different rusts to certain host plants is described and attention called to some of the curious methods of infection between the related species. A second part of the work is devoted to species of rusts and their biology. Extended bibliographies are given and the work is completely indexed by species of fungi and by the host plants.

The grain smuts, L. A. MERRILL and B. F. ELIASON (*Utah Sta. Bul. 84, pp. 35–44*).—Compiled notes regarding grain smuts, the information being largely drawn from the publications of this Department and the various experiment stations, and the results of the authors' observations and the occurrence and distribution of smuts throughout the State are given. The efficiency of various fungicides for the treatment of seed is compared and directions given for their use. Based upon the efficiency, ease with which the treatment may be followed, cost of treatment, etc., the use of formalin is recommended.

Treatment of seed grain for the prevention of smut (*Wisconsin Sta. Rpt. 1903, pp. 284–292, figs. 2*).—This consists of abstracts of previous publicatons by R. A. Moore, entitled Treating Seed Oats for the Prevention of Smut (E. S. R., 13, pp. 36, 962; 14, p. 957), Oat Smut Investigations for 1902 (E. S. R., 14, p. 958), Oat Smut in Wisconsin (E. S. R., 13, p. 962), and Prevention of Oat Smut and Potato Scab (E. S. R., 14, p. 978).

The treatment of seed oats for the prevention of smut (*Wisconsin Sta. Rpt. 1903, pp. 363-367*).—Abstracts are given of the following previous publications: The Hot-Water Treatment for the Prevention of Smut in Oats, Wheat, and Barley, by E. S. Goff (E. S. R., 8, p. 240); A Trial of "Ceres Pulver" for the Prevention of Smut in Oats, by E. S. Goff (E. S. R., 10, p. 762); The Prevention of Oat Smut, by E. S. Goff (E. S. R., 13, p. 255); The Influence of Formaldehyde on the Germination of Oats, by F. Cranefield (E. S. R., 13, p. 918); The Influence of Formaldehyde on the Germination of Oats, by F. Cranefield (E. S. R., 14, p. 975), and The Influence on the Growth of Oat Plants and the Yield of Grain Resultant from Treating the Seed with Formaldehyde, by F. Cranefield.

In the last paper enumerated are given the results of experiments in 1903, in which the author studied the influence of treatment on the growth of oat plants and on the yield of straw and grain. Different lots of oats were soaked for 20 minutes in solutions of formaldehyde, as follows: One pint to 10 gal. of water, 1 pt. to 25 gal., 1 pt. to 36 gal., and 1 pt. to 50 gal., the growth of the plants being compared with one lot untreated. As far as the growth was concerned but little difference was noted in the plants of the different lots, except where seed was treated with 1 pt. to 10 gal. of water. In this case considerable injury was done, and as the germination was poor the plants had considerably more room for growth than in the other lots. In testing the effect on yield fortieth-acre plats were used, the seed being treated as above. The only positive injury noted was in the case where the strongest solution was used.

From the experiments reported it appears that while a portion of the seed may be destroyed even when treated with formaldehyde solution as dilute as 1 pt. to 50 gal. of water, under practical field conditions the yield is not appreciably affected by treating seed with a solution as strong as 1 pt. to 36 gal.

The relation between Pleospora and Helminthosporium, H. Diedicke (*Centbl. Bakt. u. Par., 2. Abt., 11 (1903), No. 2, pp. 52-59*).—In continuation of the author's experiments (E. S. R., 14, p. 877), a report is given on the relation between certain species of Pleospora and Helminthosporium. It appears from his investigations that *P. trichostoma* occurring on rye is probably not to be associated with any species of Helminthosporium but rather with some species of Alternaria. The conidial stages of *H. teres*, *H. avenæ*, *H. bromi*, *H. gramineum*, and *H. tritici repentis* are associated with the perithecial stages of Pleospora, and they should be properly designated as belonging to that genus.

Clover sickness and its cause, H. T. Güssow (*Jour. Roy. Agr. Soc. England, 64 (1903), pp. 376-391, figs. 2*).—The author reviews the various causes which from time to time have been suggested for the condition known as clover sickness. Whether this condition is always due to a parasitic fungi is said to be a matter for further inquiry, but the cause of a disease reported in 1901 in the Rothamsted experiments is said to have undoubtedly been the fungus *Sclerotinia ciborioides*.

Not only is red clover subject to attacks of this fungus but alfalfa, white clover, and other species are affected by it. The author says that in the earlier stages of the disease when the dark spots first appear on the leaf spraying with Bordeaux mixture would modify if not check the progress of the disease.

Potato diseases of India, E. J. Butler (*Agr. Ledger, 1903, No. 4 (Crop Disease and Pest Ser., No. 7), pp. 87-124, figs. 9*).—A description is given of the fungus diseases to which the potato is subject in India, particular attention being given to the potato blight due to *Phytophthora infestans* and a disease to which the name "bangle" blight is given. This latter disease is characterized by the sudden wilting of the green tops, and is first noted by the occurrence of wilted plants here and there throughout the field. The tubers are checked in their growth and the yield is lessened and in many cases the tubers are rotten when dug.

A characteristic of the disease is shown in the blackened ring of fibrovascular

bundles in the tubers and where such potatoes were used for seed a diseased crop usually followed. The cause of this disease is thought to be possibly the same as that described in the United States and elsewhere under the name of *Bacillus solanacearum*. A number of other diseases of less frequent occurrence are briefly described.

The relation of date of digging potatoes to the development of the rot, L. R. Jones and W. J. Morse (*Proc. Soc. Prom. Agr. Sci., 1904, pp. 90–95*).—An account is given of the authors' investigations on the relation between the late blight (*Phytophthora infestans*) and the rotting of potatoes after harvest. This account is based on the investigations which have been hitherto reported (E. S. R., 14, p. 1084; 15, p. 1088).

The brown rot of the Swedish turnip, M. C. Potter (*Jour. Bd. Agr.* [*London*], *10* (*1903*), *No. 3, pp. 314–318, pl. 1*).—A short account is given of the brown rot of Swedish turnips which has been under observation since 1898.

The disease was noticed as beginning in October on roots still growing in the fields and was frequently met with in storage. The disease is unquestionably due to the action of bacteria and is attributed to the same organism as that causing the black rot of turnips and cabbage, *Pseudomonas campestris*. The author has succeeded in producing all stages of the disease on perfectly sound roots by inoculation with pure cultures of the bacteria isolated from naturally decaying roots. This organism of decay appears confined to the Cruciferæ. The author suggests prolonged rotation of crops as a means of preventing serious injury by disease.

The occurrence of this disease in the United States is commented upon and the author believes that the greater immunity observed in England may be due to the system of rotation of crops adopted there, as well as the fact that the summer temperature in England is not so high as it is in this country. It has been shown that a temperature of 80 to 90° F. accompanied by a damp atmosphere particularly favors the development of the bacteria.

Two plant diseases in Hawaii, J. G. Smith (*Hawaii Sta. Press Bul. 9, pp. 6*).—A description is given of the pineapple disease of sugar cane and a disease of coffee called the brown-eyed disease.

The pineapple disease of sugar cane, which is due to *Thielaviopsis ethaceticus*, made its appearance in Hawaii in 1903. The disease exists in a number of forms according to the different parts of the cane plant affected, and when occurring on the young seed cane it frequently injures it to such an extent that there is no germination. It is said that serious outbreaks almost invariably follow the work of some insect pest, either the cane borer or leaf hopper. Although the fungus is truly parasitic, its entrance is much facilitated by the injury caused by the insects.

The disease derives its name, pineapple disease, from the odor of the freshly cut stalks, somewhat resembling that of pineapples. This is said to be due to the formation of acetic ether by the fungus from the saccharin substances within the cane. For the protection of the cane seedlings against this fungus it is recommended that the ends be coated with tar before planting, that care be exercised in selecting seed cane, that they be perfectly sound and healthy, and that all infected stalks left after the cane has been harvested should be gathered and burned.

The coffee disease is due to the fungus *Cercospora coffeicola*. This fungus seems to be rather widely distributed and attacks both the leaves and the fruit. On the leaves it produces round or oval spots of a clear brown on the lower surface and dark brown on the upper, the center of the spots being lighter in color. On the fruit small dark spots appear. These by spreading involve about half of the fruit which soon becomes brown and dried. Considering the nature of this fungus, the author believes that the use of Bordeaux mixture or similar fungicide will hold it in check, and he gives directions for the preparation and application of this and other fungicides.

A bacterial disease of sesame, K. Malkoff (*Centbl. Bakt. u. Par., 2. Abt., 11*

(*1903*), *No. 10–11, pp. 333–336, fig. 1*).—A preliminary note is given of a disease of *Sesamum orientale* which has been recently observed in Bulgaria. From diseased specimens the author has isolated an organism and by means of inoculations has been able to produce the disease within a few days. The occurrence on the host plant is characterized by the wilting of the plants followed by their destruction. The biology of the bacteria is to be studied further.

Report on asparagus rust investigation, R. E. SMITH (*California Sta. Circ. 9, pp. 20, figs. 10*).—A preliminary account is given of investigations on the asparagus rust, the investigations being carried on in cooperation between the station and a number of the leading growers, canners, and handlers of asparagus in the vicinity of San Francisco.

After describing the nature of the disease and its injury the author calls attention to the natural conditions affecting its spread, the susceptibility of varieties to the disease, relation of time of cutting to the disease, effect of spraying, fertilizing the soil, parasites, etc. The marketable asparagus is said not to be directly affected by the rust, and the red spots often seen upon the white surface giving the stalks a rusty appearance have been recently determined as due to an entirely different cause which will be investigated during the coming season. The whole subject of the effect of the rust upon the roots and the winter condition of the rust is receiving attention.

Among the conditions affecting the spread of the disease the author has found that the amount of rust varies directly with the amount of dew, and so long as there is little or no dew there will be no rust. The relation of this fact to asparagus cultivation in California is discussed at considerable length and the effect of winds in drying the fields or spreading the disease is shown. It is recommended that all willows and other heavy-growth plants forming a shelter to the fields should be cut away, and in planting the rows should be laid out and the distance between the plants increased so as to secure as much dryness as possible. Decided differences are noted in the susceptibility of varieties, the Palmetto proving in California, as in the East, one of the most resistant.

In discussing the time of cutting asparagus the author recommends that for the present cutting should be stopped early in June, in order that the plants may obtain as much growth as possible before the appearance of the fungus. Spraying has been found to produce a decided reduction in the amount of rust, but when the expense and difficulty of the treatment are considered it is hardly to be recommended. Keeping the plants in vigorous condition by good cultivation and fertilization seems to give good results and to be practical under local conditions. Clean cultivation is particularly recommended.

The author reports the occurrence of parasitic fungi on the rust, but they appear to have had but little effect in reducing the disease. There has been noticed, however, a mold-like fungus which gives great promise of checking the rust and this will be given further investigation.

Bordeaux spraying for melon blight, E. R. BENNETT (*Connecticut Storrs Sta. Bul. 30, pp. 17–23, figs. 3*).—The results of experiments for the prevention of melon blight by the use of Bordeaux mixture are given. The fungicide was prepared by the 4–4–40 formula and tested to make sure that it was not acid. Seven sprayings were given a plat of cucumbers, comparisons being made with untreated plats. The blight appeared quite severe on the unsprayed plants, while those having been sprayed continued to grow until cold weather.

An account was kept of the cucumbers gathered. From the unsprayed portion 550 were secured, while from the sprayed plat 1,298 pickles from 2 to 2.5 in. in length were gathered. The results from spraying melons were practically the same as from cucumbers. Notes are given on the proper method of making Bordeaux mixture and the time and manner of application.

Muskmelon blight, W. M. MORGAN (*West Virginia Sta. Circ. of Information 2,*

pp. 4).—The muskmelon blight, it is said, has become a serious pest, and the station is planning a series of experiments for controlling the blight not only on muskmelons but also on watermelons. As preliminary to a statement of the results of the experiments, directions are given for checking the spread of the disease by the use of Bordeaux mixture.

Studies of the scab disease of carrots (Rhizoctonia violacea), J. ERIKSSON (*K. Landt. Akad. Handl. och Tidskr., 42 (1903), No. 4, pp. 309–334*).—The author finds that the different varieties of carrots differ to some extent in their susceptibility to Rhizoctonia. The form of the disease experimented with appeared to have the faculty of infecting other plants, both wild and cultivated. This paper is essentially the same as that noted in E. S. R., 15, p. 484.—F. W. WOLL.

Black rot of cabbage (*Wisconsin Sta. Rpt. 1903, pp. 259–262, figs. 2*).—An abstract is given of a previous publication entitled, A Bacterial Rot of Cabbage and Allied Plants, by H. L. Russell (E. S. R., 10, p. 155).

Fungus diseases of fruits in Michigan, B. O. LONGYEAR (*Michigan Sta. Spec. Bul. 25, pp. 68, figs. 42*).—This bulletin is designed as a handbook of the most common and destructive diseases of fruits in Michigan. It is based upon the publications of this Department and bulletins of various experiment stations, with notes on the author's observations.

After briefly describing the causes of the diseases, descriptions are given of a number of the more common forms of parasitic and nonparasitic diseases. Directions are given for the preparation of a number of the better known fungicides, and the bulletin concludes with general recommendations regarding spraying.

Pear blight, W. N. HUTT (*Utah Sta. Bul. 85, pp. 45–52*).—This bulletin gives a résumé of the history and nature of pear blight, together with the treatment of the disease which has been found most successful during the past 2 years at the Utah station. The distribution and history of the pear blight, which is due to *Bacillus amylovorus*, are traced and notes given on the kinds of trees attacked, difference in resistance, and the effect of soils, manures, cultivation, irrigation, and pruning on the development of the blight.

Injury to peach foliage from spraying with Bordeaux mixture and Paris green, F. W. CARD and A. E. STENE (*Rhode Island Sta. Rpt. 1903, pp. 223, 224*).—The results of an accidental application of Bordeaux mixture of ordinary strength to a peach tree are given. The tree lost its leaves, becoming nearly defoliated, but as the application was made early in the season the tree put out new leaves and by midsummer was in an apparently healthy condition.

The other injury reported was through spraying tests made in cooperation with this Department. For this purpose samples of Paris green were furnished containing free arsenious oxid, varying from 2.84 to 8 per cent. The peach trees were sprayed with a mixture of 1 lb. to 250 gal. of water. For a few days no injury could be noted, but after 10 days the trees sprayed with the stronger mixtures lost nearly all their leaves and by midsummer many of the branches were dead. Under general conditions it seems unwise to spray peach trees in leaf with either Paris green containing free arsenious oxid or with Bordeaux mixture of ordinary strength.

A root disease in tea, J. B. CARRUTHERS (*Circs. and Agr. Jour. Roy. Bot. Gard., Ceylon, 2 (1903), No. 6, pp. 111–122*).—A description is given of the root disease of tea due to the fungus *Rosellinia radiciperda*. The external effects of the fungus are described, as well as the results of culture experiments, the structure and life history of the fungus, and its distribution in Ceylon. The author notes the conditions favorable to the spread of the disease and suggests various means for its prevention. The disease seems to be widely spread and to be increasing throughout the island. Its presence is favored by decaying wood in the soil, and it finds its most successful starting point from the roots of dead trees as well as in buried prunings.

For the prevention of the disease the author recommends the isolation of all

suspected areas by digging trenches about them, the destruction of all dead roots containing the mycelium of the fungus, the opening of the soil in the holes left by the removal of the trees, the thorough draining of all plats where the disease is suspected, and the use of such fertilizers as kainit, iron sulphate, basic slag, lime, etc. It is further suggested that the practice of burying the prunings from the tea trees be discontinued.

Experiments on the treatment of downy mildew, L. Ravaz and A. Bonnet (*Ann. École Nat. Agr. Montpellier, n. ser., 3 (1903), No. 2, pp. 157–168*).—Experiments are reported in which the authors tested the relative efficiency of copper and cadmium as fungicides, the adhesiveness of various fungicides, and the action of copper on the growth of grapes. Bordeaux mixture, cadmium sulphate and lime, a simple solution of cadmium sulphate, and a solution of copper sulphate were compared, and so far as their relative efficiency in checking the downy mildew was concerned there was found but little choice.

In the experiments on adhesiveness, Bordeaux mixture, Burgundy mixture, verdigris solutions, and Bordeaux mixture, to which was added turpentine and resin, were tested. Different lots of grapevines received 1, 2, and 3 sprayings, and the adhesiveness of the different fungicides was determined by the amount of mildew observed on the vines. Where 3 sprayings were given the vines practical immunity was secured with all the fungicides.

Where 2 applications were made, the fungicides, to which resin was added, gave the best results, closely followed by ordinary Bordeaux mixture, Burgundy mixture, and verdigris solutions. Where only a single spraying was given the vines no difference in adhesiveness was noted and but slightly less disease was observed on the treated vines than on those which received no applications of fungicides.

In studying the action of chemicals on the growth of the vines cadmium and copper seemed to have about the same stimulating effect on the foliage of the crop, prolonging their attachment and increasing the intensity of coloration, although copper was found much more active in the latter respect than cadmium.

The wintering of Oidium tuckeri, O. Appel (*Centbl. Bakt. u. Par., 2. Abt., 11 (1903), No. 4–5, pp. 143–145, fig. 1*).—It is said that the powdery mildew can vegetate during the winter as isolated fragments of mycelium on the newly formed wood into which it sends its numerous irregular haustoria. In the spring of the year these anomalous strands of mycelium develop into normal growths which bear conidia, thus setting up a new infection of the mildew.

Powdery mildew and grape hybrids, E. Goutay (*Prog. Agr. et Vit. (Ed. L'Est), 24 (1903), No. 47, pp. 608, 609*).—Notes are given on the relative susceptibility of varieties of grapes to injury by the powdery mildew. Some of the newer hybrids are reported as being very susceptible to injury by the fungus, while others are nearly or quite resistant to its attack.

The treatment of the gray rot of grapes and the composition of wines, L. Degrully (*Prog. Agr. et Vit. (Ed. L'Est), 24 (1903), No. 49, pp. 464, 465*).—The results of the application of fungicides for the prevention of gray rot, as shown by the quality of the wine, are given. The vines had been covered with a powdered fungicide, made according to the formula of Sokolnicki, which consists of "alum plaster" 25 kg., cement 10 kg., gypsum 25 kg., and sulpho-steatite 40 kg. This was applied to the vines twice during the season, and under the conditions of the experiment a maximum quantity of plaster, alum, and sulphate of copper was administered to the plants.

The wine made from these plants was subjected to analysis which showed no presence of copper nor was there an excess of potassium sulphate, but the alumina present corresponded to 0.409 gm. per liter, an amount which is about 13 times as great as that tolerated.

On the treatment of the gray rot of grapes, E. Combemale (*Prog. Agr. et Vit. (Ed. L'Est), 24 (1903), No. 50, pp. 697, 698*).—A fungicide consisting of triturated

sulphur 50 kg., mineral superphosphate 25 kg., and copper steatite 25 kg. is recommended as a preventive measure against gray rot of grapes. This has been used for 2 seasons with success and according to the author did not produce any injurious or deleterious effect on the quality of the wine.

The action of silver chlorid on the gray rot of grapes, G. BOUCHARDAT (*Rev. Vit., 20 (1903), No. 521, pp. 669, 670*).—Based upon the investigations of Raulin, which showed that ammoniacal solutions of silver chlorid had a strong fungicidal action, the author reports upon this substance when used for attacks of *Botrytis cinerea*.

To prepare this solution the author dissolved 25 gm. of silver nitrate in 200 gm. of water to which was added sufficient sea salt to precipitate the silver nitrate in the form of chlorid. After precipitation strong ammonia was added sufficient to completely dissolve the precipitate, and 1 liter of the solution was made by the addition of water. When used 10 cc. of this solution was added to 12 to 15 liters of water and sprayed upon the vines.

The vines sprayed with this solution were protected against the attack of the fungus until after the second invasion, which was very light on both sprayed and check vines.

The canker fungus in rubber, J. B. CARRUTHERS (*Agr. Bul. Straits and Federated Malay States, 2 (1903), No. 12, pp. 389–392*).—An account is given of the canker fungus of rubber, which is said to have been first noticed in 1901 by the Conservator of Forests, but was not called to the author's attention until early in 1903.

The disease is due to a species of Nectria and an investigation showed that in some districts from 0.5 to 2 per cent of the trees were affected, while in others as high as 40 per cent of the rubber trees were diseased. The presence of the fungus may be generally recognized by the roughened and swollen appearance of the stems and branches. If the outer bark is removed there is seen a discolored tissue which subsequently becomes brownish in color. The canker is spread by the agency of the wind, insects, such as red ants, etc.

As preventive measures the author recommends inspection and cutting out of the diseased portions and the burning of all bark and dead branches. When trees are badly affected they should be destroyed, as the presence of the fungus tends to prevent the production of latex by the trees. There is thought to be little danger of the fungus attacking nursery stock, as the smooth bark of the young trees would, in a measure, prevent the fungus gaining a lodging place.

Investigations in Helicomycelium fuliginosum, E. DUBOURG (*Mem. Soc. Sci. Phys. et Nat. Bordeaux, 6. ser., 3 (1903), pp. 263–272*).—A study is given of a fungus observed in some worm-eaten railway timbers. The timbers prior to use had been treated with creosote for their preservation, but the liquid had not penetrated to their center and it was in this zone only that the fungus was found.

Some of the morphological and biological characteristics of the fungus, which was artificially grown on a number of media, are described. The fungus was found to secrete oxydase abundantly, especially in unaerated media. An attempt was made to determine the effect of various antiseptic solutions on the development of the organism. It was found to grow in solutions that are usually strongly antiseptic. Copper sulphate, bismuth subnitrate, and potassium fluorid even when used as strong as 1 part to 100 did not check growth. Corrosive sublimate, thymol, and salicylic acid 1 to 10,000 were insufficient, but when used in strengths of 1 to 5,000 checked all growth. Phenol, naphthalin, creosote, and carbolineum 1 to 2,000 destroyed the fungus, and potassium arsenite 1 to 200 had a similar effect.

To test the practical application of different treatments of wood for preservation when placed in the ground, experiments are to be conducted in which railway sleepers are to be injected with a number of fungicides and their relative efficiency noted.

Notes on recent experiences with dry rot, J. HUNTER (*Trans. and Proc. Bot. Soc. Edinburgh, 22 (1902), pt. 2, pp. 106–109*).—Notes are given on observations regarding the dry-rot fungus *Merulius lacrymans* and the effect of copper sulphate upon the mycelium of the fungus. A warning is given against the use of imperfectly seasoned timber and the inclosing of timber where good ventilation is impossible.

ENTOMOLOGY.

Proceedings of the sixteenth annual meeting of the Association of Economic Entomologists (*U. S. Dept. Agr., Division of Entomology Bul. 46, pp. 113, pls. 2, fig. 1*).—At this meeting, which was held at St. Louis, Mo., December 29–31, 1903, a number of papers were presented, the majority of which have already been noted (E. S. R., 15, pp. 545–548). The following notes refer to papers which have not been previously abstracted:

J. S. Hine presented some observations on the Tabanidæ (pp. 23–25). Different species of Tabanidæ are found to have different egg-laying habits, some of which suggest an easy means of extermination. The egg masses of *Tabanus trimaculatus* and *T. stygius* were so large and conspicuous that it was found possible to collect 60,000 eggs in one hour. This is suggested as a possible method of controlling these pests. The last named species was found to deposit its eggs almost exclusively on the leaves of sagittaria.

Ravages of grasshoppers on the ranches of Montana were discussed by R. A. Cooley (pp. 41–43). The grasshoppers did most damage along the Yellowstone River between Miles City and Big Timber. In some places the grass was so completely destroyed that ranchers were forced to sell their stock. Not a single specimen of the Rocky Mountain locust could be found. The most common species were *Aulocara elliotti*, *Melanoplus atlanis*, and *Camnula pellucida*. The use of contagious diseases in controlling grasshoppers was tried without satisfactory results.

H. Osborn strongly urged the desirability of greater stability in nomenclature (pp. 56–59). The speaker suggested the appointment of a committee to correspond with entomologists and prepare a list of preferred names for 300 of the most common species of injurious insects.

C. V. Piper gave an account of the injuries to the range from *Peranabrus scabricollis* (pp. 60, 61). This insect was stated to be injurious to range grasses and wheat in Douglas County. The pest can apparently be successfully controlled by ditching and fencing. Attempts to inoculate with the South African mucor were fruitless.

W. Newell presented notes on the insects of Georgia for 1903 (pp. 103–105). Particular mention was made of peach borer, fruit-tree bark-beetle, cotton caterpillar, chinch bug, Hessian fly, Mexican boll weevil, and *Chilocorus similis*. The last-named species was obtained from the Division of Entomology of this Department and was said to have increased rapidly.

W. C. Britton (pp. 105–107) gave economic and biological notes on green-pea louse, apple plant-louse, pear psylla, onion thrips, asparagus bettles, tent caterpillar, and European mantis.

C. M. Weed presented an account of the brown-tail moth in New Hampshire (pp. 107, 108). The region about Newburyport was said to be quite generally infested. Notes are also given on the food plants of this insect. The same author described some experiments carried out by A. F. Conradi in exterminating black flies (pp. 108, 109). It was found that the larvæ of these insects could readily be destroyed by pouring phinotas oil into the water in which they were living. This oil is heavy and comes in contact with the larvæ on the rocks. It was also found possible to brush the larvæ from the rocks by stiff brooms and catch them in fine wire screening.

Some miscellaneous results of the work of the Division of Entomology, VII (*U. S. Dept. Agr., Division of Entomology Bul. 44, pp. 99, pl. 1, figs. 19*).—Some of the aphides affecting grains and grasses of the United States are discussed by T. Pergande (pp. 5–23). The author is of the opinion that the American apple plant-louse and the grain louse are identical and that *Aphis mali* is a distinct species belonging to a different genus from the grain louse of Europe. Notes are given on the habits, food plants, and life history of this species and detailed descriptions are presented of *Macrosiphum granaria*, *M. cerealis*, and *M. trifolii*. The proper name of the European grain louse is supposed to be *Siphocoryne avenæ*.

F. H. Chittenden discusses the chestnut weevils and other nut-feeding species (pp. 24–39). The weevil injuries to chestnuts are due to the attacks of *Balaninus proboscideus* and *B. rectus*. Notes are given on the habits of these species as well as on *B. caryæ* which is injurious to hickory nuts and also on various other species of weevils. The use of arsenical or contact poisons in controlling these pests is not satisfactory. Better results are obtained from bisulphid of carbon, by heating the nuts, or by keeping them in cold storage. The same author presents an account of the cowpea-pod weevil (pp. 39–43). This species is *Chalcodermus æneus*. The best remedies in controlling it in cowpeas appear to be fumigation of the seed with bisulphid of carbon and spraying with arsenate of lead combined with Bordeaux mixture.

Additional observations on the tobacco stalk-weevil are presented by J. C. Bridwell (pp. 44–46). This insect attacks potato, tobacco, and various related wild species of plants. The weevil hibernates in the stems of tobacco or Jamestown weed. In controlling the pest, best results are obtained from burning the stalks of these plants.

F. Maskew reports results of experiments with Fuller's rose beetle in California (pp. 46–50). Where this pest attacks strawberry plants it is recommended that infested plants be pulled up and destroyed as soon as they begin to wilt. Carbon bisulphid is also recommended as well as drowning by irrigation wherever the latter method can be practiced.

C. L. Marlatt gives an account of importations of beneficial insects into California (pp. 50–56). *Scutellista cyanea* is reported as being wonderfully effective in destroying the black scale in California. The larva of this parasite feeds upon the eggs of the black scale. The parasite is easily distributed from place to place and maintains itself vigorously. It is active throughout nearly the whole year. It is said that *Rhizobius ventralis* has shown itself to be very efficient in destroying the cottony maple scale which is injurious to apples in California.

J. S. Hine presents a report on insects injurious to stock in Louisiana (pp. 57–60). During the author's study 5 species of horse flies were observed, viz, *Chrysops flavidus*, *Tabanus atratus*, *T. lineola*, *T. costalis*, and *T. quinquemaculatus*. A number of natural enemies of these pests were observed. It is suggested that large numbers of adult horse flies could be captured by the use of trap window screens.

C. L. Marlatt presents a brief account of the distillate spray in California (pp. 60, 61). It has been found that 2 per cent strength of this spray does not injure foliage but is not always completely effective.

F. V. Theobald gives an account of three British fruit pests which may be introduced on nursery stock (pp. 62–70). These pests are *Laverna atra*, *Psylla mali*, and *Eriophyes ribis*.

The cherry fruit fly is discussed by F. H. Chittenden (pp. 70–75). This pest is reported as prevalent in the District of Columbia, but as being susceptible to inclement weather. Brief notes are given on methods of controlling the pest.

Notes are also given on the natural coloration of silks of lepidoptera by G. Leverat and A. Conte (pp. 75–77).

Some preliminary notes on the clover-seed chalcis fly (*Bruchophagus funebris*) (pp. 77–80).

Salt-marsh caterpillar on cotton, by W. E. Hinds (pp. 80–84), and numerous miscellaneous topics.

Report of the government entomologist for the year 1902, C. P. Lounsbury (*Cape Good Hope Dept. Agr., Rpt. Govt. Ent. 1902, pp. 41*).—An account is given of the success which has thus far attended the introduction into Cape Colony of predaceous and parasitic insects from this and other countries for the purpose of keeping injurious insects in check.

The lime-sulphur-salt wash was found effective in controlling *Diaspis pentagona* and kerosene emulsion produced good results in combating the Bryobia mite of prune trees. Lime-salt-sulphur is more efficient, however, both as a summer and winter wash. African coast fever is believed to be carried by *Rhipicephalus decoloratus*. Several experiments were carried on for the purpose of obtaining evidence regarding the etiology and means of distribution of heartwater, malignant jaundice, and African coast fever.

Report of the government entomologist for the year 1903, C. P. Lounsbury (*Cape Good Hope Dept. Agr., Rpt. Govt. Ent. 1903, pp. 46, pls. 7*).—Brief notes are given on regulations regarding plant importations and nurseries. The desirability of an agricultural experiment station near Cape Town is urged. Experiments with ticks as related to African coast fever showed that *Rhipicephalus appendiculatus* may transmit the disease. Negative results were obtained with *R. sanguineus*.

Further investigations on heartwater indicated that sheep and cattle are subject to the disease and that it is transmitted through the agency of *Amblyomma hebræum*. Persian sheep are susceptible. The disease is not carried by the brown tick. Malignant jaundice in dogs is caused by infection with *Piroplasma canis*, which is carried by *Hæmaphysalis leachi*. Detailed notes are given on the biology of the tick and on the developmental forms of the blood parasite.

Insect record for 1902, C. M. Weed (*New Hampshire Sta. Bul. 102, pp. 70–78, figs. 4*).—Notes are given on the San José scale, brown-tail moth, gypsy moth, cankerworms, codling moth, squash bug, tent caterpillars, oyster-shell bark-louse, white fly, pear-tree psylla, tussock moth, etc. The habits and life histories of these insects are discussed and brief directions are given for combating the pests.

[Monthly bulletin of the division of zoology,] H. A. Surface (*Pennsylvania State Dept. Agr., Mo. Bul. Div. Zool., 2 (1904), No. 2, pp. 35–64, pls. 2, figs. 6*).—Notes are given on the preparation and application of insecticides and fungicides. Lines of treatment are suggested for potato diseases. Methods of exterminating wild mustard and other weeds are described, together with notes on rose insects and remedies for plant lice and scale insects.

[Monthly bulletin of the division of zoology,] H. A. Surface (*Pennsylvania State Dept. Agr., Mo. Bul. Div. Zool., 2 (1904), No. 3, pp. 67–96*).—Brief notes on the repression of insects and fungus diseases and also on San José scale, diseased fruit, fire blight, melon insects, mosquitoes, insects injurious to domesticated animals, etc.

Some fern and orchard pests, W. W. Froggatt (*Agr. Gaz. New South Wales, 15 (1904), No. 6, pp. 514–518, pl. 1*).—*Neosyagrius cordipennis* is described as a new genus and species of weevil injurious to maiden-hair fern. The best means of ridding ferns of these pests is to submerge the pots and plants in a tub of lukewarm water. The beetles soon come to the surface of the water and may easily be captured. Notes are also given on the habits, life history, and means of combating *Syagrius fulvitarsis*, a fern pest, and *Baris orchivora*, a weevil injurious to greenhouse orchids.

Report of nursery inspection for the State of Wisconsin, E. P. Sandsten (*Wisconsin Sta. Rpt. 1903, pp. 391, 392*).—Notes are given on the purpose of the

nursery inspection law, and also a list of nurseries which have been inspected in Wisconsin.

Catalogue of the exhibit of economic entomology at the Louisiana Purchase Exposition, St. Louis, Mo., 1904, E. S. G. Titus and F. C. Pratt (*U. S. Dept. Agr., Division of Entomology Bul. 47, pp. 155*).—In the exhibit of the Division of Entomology at the Louisiana Purchase Exposition an effort has been made to illustrate the principal injurious insects of North America in all of their stages. Particular attention has been given to the economic relations of insects and special cases have been prepared containing the models of the chief injurious insects. The bulletin contains in detail a list of all species in the exhibit.

Reading course in economic entomology, C. W. Woodworth (*California Sta. Circ. 10, pp. 18*).—On account of the number of applications for information and instruction in economic entomology, an arrangement has been made to conduct a reading or correspondence course in this subject as a part of the extension work of the California State University.

The readers who enroll for this course will be furnished with station bulletins which will serve as text-books. The work accomplished in this way will be put to the credit of the individuals who take the course and will be accepted as a part of a residence course upon subsequent matriculation at the university. Detailed directions are given on the guidance of students in the study of insects and in the use of the literature to which they are referred.

The attraction of colors and odors for insects, J. Pérez (*Mém. Soc. Sci. Phys. et Nat. Bordeaux, 6. ser., 3 (1903), pp. 1–36*).—Based upon extensive experiments and observations the author has reaffirmed his opinion expressed in 1894 that insects are not attracted to flowers by their color alone.

After reviewing some recent literature regarding the attraction of insects by flowers, an account is given of observations on the attraction of various species of Bombus, Apis, Sphinx, etc., by plants growing under natural conditions, and of experiments carried on with flowers grown under conditions capable of control. As a result it is concluded that insects are guided from a distance to masses of flowers by their perfume alone. Where flowers are grown singly insects are attracted generally by color, and where the distance is small the odor also assists in attracting and directing the movements of the flying insects. In the case of apetalous flowers the perfume alone is a directive agent.

Monograph of the genus Saperda, E. P. Felt and L. H. Joutel (*New York State Mus. Bul. 74, pp. 86, pls. 14, figs. 7*).—A systematic account is presented of the genus Saperda with notes on the subgeneric grouping, bibliography, distribution, and specific relations. A list is given of the American species of the genus with a key for their identification and a detailed description of each species. The American species were compared with European and Asiatic forms. The habits, life history, natural enemies, and means of combating the more important species are discussed in detail, with references to the literature of the subject.

The Mexican cotton-boll weevil, W. D. Hunter and W. E. Hinds (*U. S. Dept. Agr., Division of Entomology Bul. 45, pp. 116, pls. 16, figs. 6*).—This bulletin contains a detailed summary of all available information regarding the habits, life history, depredations, and means of control of the cotton-boll weevil. The authors give an account of the destructiveness of the beetle and history of its introduction into Texas.

The insect is described in all of its stages and notes are given on the habits of the larva and adults upon various parts of the cotton plant. Experiments carried out for the purpose of determining whether other plants than cotton might serve as food for this insect gave negative results. In these experiments various species of Hibiscus were used as well as sunflower, bindweed, pigweed, ragweed, etc. It is con-

cluded that cotton is the only food plant of the boll weevil. Notes are given on a number of insects which have been mistaken for the boll weevil.

During the investigation of this insect it was found that cotton-seed meal could not be made to serve as food for the weevils and that it showed no power of attracting them. Negative results were also obtained in testing the value of sweets as an attraction for the weevil. A detailed account is presented of the field work of the Division of Entomology in the study of this pest and notes are given on the length of time required by the insect to pass through its various stages.

The average length of the generation of the cotton-boll weevils is believed to be about 42 days. This makes it possible for 5 generations to develop between May 1 and December 1. In one test it was found that about 16 per cent of the beetles were able to hibernate successfully. The influence of severe weather upon the weevil is not so great as was at first supposed, but is nevertheless unfavorable to the insect.

In controlling this pest, the authors believe "that the destruction of the stalks in the early fall is the most effective method known of actually reducing the numbers of the weevil." This method is, therefore, recommended as the most important one for insuring success in cotton growing for the coming year. Some difference was noted in the susceptibility of various cottons to weevil injury. The Egyptian cotton was most severely injured, followed by Sea Island, Cuban tree cotton, and Kings Improved. The relative amount of injury appears to depend somewhat upon the hairiness of the stems. The hairs on the stems hinder the movements of the beetles.

There appears to be no method of preventing the spread of the weevil to any latitude where cotton can be grown, but the insect can probably be controlled more successfully in the northern than in the southern portion of the cotton belt. Notes are given on the fungus diseases and parasitic and predatory insect enemies of the weevil. Recommendations already made by the Division of Entomology regarding the cultural means of control are repeated. Spraying is considered futile.

San José scale, E. R. Bennett (*Connecticut Storrs Sta. Bul. 30, pp. 1–16, figs. 5*).—The author made use of an opportunity to take part in the spraying of 11,000 peach and plum trees on a large fruit farm. The work was begun on March 10. The lime-sulphur-salt wash is used in the proportion of 25 lbs. lime, 20 lbs. sulphur, and 15 lbs. salt to 50 gal. water. The author believes that whatever formula is adopted the amount of lime should exceed that of sulphur.

During the season's tests it was found sufficient to boil the materials for from 30 to 45 minutes. The lime-sulphur spray did not have any injurious effect upon the skin of the workmen. A test was made of the Oregon formula, during which it appeared that the copper sulphate did not increase the effect of the solution. In order to make a thorough application of the lime-sulphur wash it is recommended that the trees be previously pruned. The wash remained on the trees in a good coating for at least 3 months.

The cost of application was about 6 cents per tree. The results were very effective in the destruction of San José scale. Leaf curl was also largely prevented.

The pernicious or San José scale insect in New Hampshire, C. M. Weed (*New Hampshire Sta. Bul. 109, pp. 73–83, figs. 3*).—Brief notes are given on the distribution of the San José scale in New Hampshire. Spraying experiments with undiluted kerosene and lime-sulphur-salt wash gave unsatisfactory results. The insect was apparently eradicated by treatment with calcothion. A copy is given of the nursery-inspection law together with brief notes on the preparation of insecticides.

Treatment of San José scale, J. H. Stewart (*West Virginia Sta. Circ. of Information 1, pp. 4*).—Brief notes on the use of mixtures and kerosene and crude oil with water and also on the application of a lime-sulphur spray in controlling the San José scale.

The codling moth, E. D. Ball (*Utah Sta. Bul. 87, pp. 104–145, pls. 7, fig. 1*).—The codling moth is considered to be the worst pest with which the fruit growers

have to contend in Utah. From 60 to 90 per cent of untreated apples are infested with this pest.

Detailed notes are given on the appearance and habits of the insect in its different stages. The first brood of moths in Utah appears shortly after the apples bloom. In warm weather the moths lay their eggs within a day or two after emerging. At Logan the eggs were laid from June 1 to 25. About 90 per cent of the eggs for the first brood were deposited upon the fruit. The moths of the second brood appear from July 20 to August 20, and the eggs of the second brood were deposited between July 22 and September 10.

Evidence is presented to show that there are 2 definite broods and no more. The codling moth attacks chiefly the apple but also infests pears and occasionally stone fruits. The damage done by the 2 broods is in proportion to their numbers, and the second brood is about 5 times as numerous as the first.

Of the many methods which have been proposed for destroying this insect only two are effective, viz, spraying and banding the trees. Notes are given on the materials and apparatus suitable for spraying. The first application should be made from above downward so as to fill the calyx cups. This application should be made as soon as possible after the blossoms fall. A second spraying should be applied within from 10 days to 2 weeks.

The author believes that if the first two applications are thoroughly and carefully made later sprayings will be unnecessary. Paris green was used for this purpose at the rate of 1 lb. to 50 gal. of water. An examination of Paris green as observed in Utah indicated that this product is rarely adulterated. It is believed not to be necessary to add lime to Paris green to prevent its burning the foliage.

Bands should be placed on the trees a few days before the first worms crawl out and should be kept on until fall. The bands should be examined every 9 days during the existence of the first brood and once at the end of the season. The total cost of spraying was found to be about 1 per cent of the value of the crop. It was found possible to harvest from 90 to 95 per cent of sound apples by proper spraying and banding. Among remedies of little or no value mention is made of trap lanterns, winter spraying, hogs in orchards, picking up windfalls, and air-pressure sprays.

The brown-tail moth in New Hampshire, C. M. Weed (*New Hampshire Sta. Bul. 107, pp. 47–60, figs. 10*).—The brown-tail moth was first noticed in New Hampshire in 1899 and has since been introduced in several towns, so that the southeastern portion of the State is quite badly infested. Notes are given on the habits and life history of this insect.

A brief account is given of the damage to trees from the depredations of the brown-tail moth, and also of a skin disease in man caused by the nettling hairs of the caterpillars. A list is given of the towns infested by the pest. As treatment for this insect the following remedies are suggested: Cutting off and burning the winter nests, and spraying with arsenate of lead in the spring after the leaves have developed.

Some recent investigations on the black-currant gall mite, W. E. Collinge (*Birmingham, England: J. G. Hammond & Co., Ltd., 1904, pp. 12, pl. 1, fig. 1*).—An elaborate account is presented of the habits and life history of *Eriophyes ribis*, together with notes on related species. Methods of distribution, food plants, and remedial measures are discussed. Neither fumigation nor the use of spraying fluids has been attended with satisfactory results. Cutting and burning infested bushes will help in exterminating the pest in any given locality.

Black-currant mite (*Jour. Dept. Agr. and Tech. Instr. Ireland, 4 (1904), No. 4, p. 702, pl. 1*).—The only way of eradicating this pest is to dig up and burn all infested bushes.

The striped cucumber beetle, W. M. Morgan (*West Virginia Sta. Circ. of Information 3, pp. 4*).—In combating this pest the author recommends the destruction of

all rubbish, planting squashes as trap crops, and spraying melon seedlings with Bordeaux mixture.

Leather-jacket grubs (*Jour. Dept. Agr. and Tech. Instr. Ireland, 4 (1904), No. 4, pp. 719–721, figs. 2*).—The larvæ of crane flies are said to be serious pests in grain fields and meadows in Ireland. Careful plowing and the use of fertilizers are recommended in controlling these pests.

Grasshopper and cricket outbreaks, J. M. Aldrich (*Idaho Sta. Bul. 41, pp. 289–304, pl. 1, figs. 3*).—The Rocky Mountain locust was not concerned in any of the recent outbreaks in Idaho. The most important species was *Camnula pellucida*. The most serious outbreaks occurred on Big Camas prairie and near Market Lake. The duration of a locust plague appears to be about 5 years, and is apparently brought to an end by the combined action of the natural enemies of the locust.

Experiments with the South African grasshopper fungus were quite unsatisfactory. An experiment with crude petroleum showed that the locusts could be destroyed by the use of this remedy but that the method was too expensive. Burning under straw was recommended and also the use of hopperdozers. The author also mentions such remedies as plowing under the eggs, the use of irrigation ditches, and poisoning with the Criddle mixture.

An account is presented of the depredations of *Anabrus simplex*. This cricket hatches most extensively in arid foothills and feeds on sagebrush. The pest has been kept off from cultivated fields by the use of irrigation ditches and by driving in swarms.

Control of the brown ant (Solenopsis geminata) in orange orchards, O. W. Barrett (*Porto Rico Sta. Circ. 4, pp. 3*).—This ant normally feeds on the honey wax secreted by scale insects. Under certain conditions, however, it attacks citrus trees, causing an excretion of gum upon which it feeds. The ants also attack the flowers, young fruit, terminal buds, and small twigs. In order to prevent the ants from ascending the trees it is recommended that the trunks of trees be painted with a mixture containing a yellow resin, linseed oil, and tobacco decoction. For destroying the ants in their nests the use of a mixture of resin 2 parts, sal soda 1 part, and tobacco decoction 1 part is recommended. This mixture may be applied directly in the galleries of the nests. This circular is issued in both English and Spanish editions.

The chemical composition of some insecticides for the potato beetle, R. Harcourt (*Ontario Agr. and Expt. Union Rpt. 1903, pp. 59–62*).—An account is given of the proper composition of Paris green with notes on its use as an insecticide, especially in the control of potato beetles. The author discusses the use of London purple, lead arsenate, slug shot, Bug Death, and certain other proprietary insecticides.

Paris green spraying experiments, J. K. Haywood (*U. S. Dept. Agr., Bureau of Chemistry Bul. 82, pp. 32, pls. 2*).—The experiments reported in this bulletin were undertaken for the purpose of determining how much soluble arsenious oxid may be present in Paris green without injuring the foliage. It was found that the soluble arsenious oxid in a sample of Paris green may be of two kinds, viz, that which is readily soluble in water and that which becomes soluble by decomposition of poorly made Paris green.

Samples of Paris green were obtained and the amount of soluble arsenious oxid carefully determined. The amounts of soluble arsenic were then artificially increased if necessary so that samples were obtained which contained amounts varying from 2.24 to 8 per cent. As a result of numerous spraying experiments it is concluded that the following amounts of soluble arsenious oxid are safe when sprayed without the use of lime, viz, for apple trees, 6 per cent; for pear trees, 6 per cent; for plum trees, 4 per cent, while with the use of lime the following amounts are regarded as safe, viz, for apple trees, 7 per cent; for pear trees, 7 per cent; for plum trees, 5 to 6 per cent; and for peach trees, 4 to 5 per cent.

It is not considered safe to use any Paris green on the peach trees without the addition of lime. The difference in the effect produced by Paris green when sprayed with and without the addition of lime is so great that the use of lime is recommended in all cases.

Tobacco extract and its application in combating injurious insects, A. SMIRNOFF (*Svenska Trädgårdsför. Tidskr., 1903, No. 4, pp. 60–62*).

Fumigation practice, C. W. WOODWORTH (*California Sta. Circ. 11, pp. 27, figs. 24*).—This circular contains in a slightly revised and condensed form the material presented in Bulletin 122 of the California Station (E. S. R., 11, pp. 64, 65).

Gasolene as a remedy against enemies of the squash, cucumber, and pumpkin, F. W. CARD and A. E. STENE (*Rhode Island Sta. Rpt. 1903, p. 216*).—Gasolene was tested as a remedy for the squash borer and the larvæ of the striped beetle. Holes were made in the ground about 7 in. deep, and from 2 to 4 teaspoonfuls of gasolene were poured in each hole. The method proved wholly ineffective against these insects.

Seed and soil treatment and spray calendar, W. J. GREEN and A. D. SELBY (*Ohio Sta. Bul. 147, pp. 41–53*).—This is a revised edition of Bulletin No. 102 of the same station (E. S. R., 11, p. 274). The information contained in the bulletin is also published in a folio form.

Foul brood (*Jour. Dept. Agr. and Tech. Instr. Ireland, 4 (1904), No. 4, pp. 723–729, pls. 3*).—The sources of infection, symptoms, and treatment of this disease are described in detail. In preventing foul brood it is recommended that hives be placed on dry stands, that the hives be kept clean and tight, that old combs be rejected and old colonies strengthened by combination, and that pieces of naphthalin be kept in each hive.

FOODS—NUTRITION.

Breakfast foods, F. W. ROBISON (*Michigan Sta. Bul. 211, pp. 25, charts 2*).—The principles of nutrition are discussed and the results of analyses of 48 samples of breakfast foods and similar goods are reported. In addition to the usual constituents the insoluble starch and the materials soluble in water (ash, protein, sucrose, dextrin, and soluble starch) were determined. The insoluble starch varied from 17.59 to 77.13 per cent, being over 40 per cent in all but 8 cases. The total soluble material ranged from 2.75 to 55.15 per cent, and the dextrin from 1.02 to 25.50 per cent. The author's conclusions follow:

"The breakfast foods are legitimate and valuable foods.

"Predigestion [i. e., rendering insoluble material soluble by malting or other treatment] has been carried on in the majority of them to a limited degree only. The price for which they are sold is as a rule excessive and not in keeping with their nutritive values.

"They contain as a rule considerable fiber, which while probably rendering them less digestible at the same time may render them more wholesome to the average person.

"The claims made for many of them are not warranted by the facts. The claim that they are far more nutritious than the wheat and grains from which they are made is not substantiated. They are palatable as a rule and pleasing to the eye.

"The digestibility of these products as compared with highly milled foods, while probably favorable to the latter, does not give due credit to the former, because of the healthful influence of the fiber and mineral matter in the breakfast foods.

"Rolled oats or oatmeal as a source of protein and of fuel is ahead of the wheat preparations, excepting of course the special gluten foods, which are manifestly in a different class."

West Indian starches, W. R. BUTTENSHAW (*West Indian Bul., 5 (1904), No. 1, pp. 1–40, figs. 15*).—West Indian starch-bearing plants and the methods followed by

the author in separating starches are described, and the results of investigations of the microscopical character of the starch grains of a large number of plants are reported, including the following: Sour sop, green mango, mango kernel, crab's eye (*Abrus precatorius*), pigeon pea (*Cajanus indicus*), red pea, yam bean, cho-cho (*Sechium edule*) nightshade, 3 varieties of Ipomœa, four o'clock, pink coralita (*Antigonon insigne*), cassava, breadfruit, 2 varieties of canna, arrowroot, ginger, banana, plantain, yampie (*Dioscorea trifida*), 5 varieties of yam, tannia (*Colocasia esculenta*) wild and cultivated, maize, and guinea corn.

The large number of starches studied emphasizes the fact that the principal sources of starch in the West Indies are the roots of the plants rather than in the seeds. All the starches obtained from roots and tubers, the author states, showed a play of colors with polarized light and may be readily grouped in 2 divisions. "In the first are those bounded by rounded surfaces (i. e., either oval or ovate); hilum and concentric rings clearly visible. The examples are the yams, the cannas, arrowroot, and ginger. It will at once be noticed that these plants belong to natural orders which are not far removed from one another, and emphasis is added to this when it is observed that among the remaining starches in this group are to be found those of the tribe Museæ (banana and plantain).

"With regard to the remaining 'root' starches, they all agree in several characters. They all show some coloration with polarized light, and among the many-angled there are some rounded forms, sugar-loaf forms being often present. There is so much similarity among these starches that it will not be found an easy matter to distinguish them until details as to appearance of hilum, measurements, etc., are taken into account. The only starch in this group that is not a 'root' starch is that obtained from the green mango, just as the only 'seed' starch in Class I was mango starch. . . . The further study of fruit starches would, perhaps, be a profitable one. So far as can be seen at present there is very little uniformity. . . . As a general rule it is stated that seed starches (at any rate, those of the cereals) show no iridescence with polarized light; mango-seed starch, however, gives quite a brilliant play of colors."

In general the leguminous starches showed little or no iridescence when examined with polarized light and considerable uniformity was observed. "An exception has, however, to be noted in the case of groundnut starch (*Arachis hypogæa*), as also in the case of the starch from the root of the yam bean (*Pachyrhizus tuberosus*). In the case of the latter we have what may be called the usual dicotyledonous 'root' form of starch instead of the typical leguminous seed form. Evidently the striking uniformity in the case of leguminous starches is confined to the seeds. The only cereal starches on this list will be found classed with the leguminous starches; the only points of resemblance, however, are the invisibility of concentric rings, the absence of iridescence with polarized light, and the presence of a more or less stellate hilum. The starches of breadfruit and jack fruit are placed by themselves in the class which contains wheat, barley, rye, etc."

In his investigations the author has followed the classification of starches suggested by Blyth, but believes that the systems for the classification of starches now in use are unsatisfactory and should be revised.

"Another interesting point is brought out by this investigation, which appears to be worthy of mention here. While in most cases there is a more or less distinct resemblance between the starch grains of plants in any particular family, several instances have been recorded where there is a decided variation. . . . [Among the starches examined] there are some that might be utilized as producers of starch for laundry purposes, while in other cases easily digested food, suitable for infants and invalids, might be obtained, as for example, from the cho-cho root and the yam bean."

Roots and tubers as food (*Iowa Agr., 4 (1904), No. 6, pp. 242–244*).—The composition and food value of a number of sorts of roots and tubers are briefly discussed.

The composition of different sorts of artichoke tubers harvested in spring and fall, P. Behrend (*Jour. Landw., 52 (1904), No. 1–2, pp. 127–143*).—Analyses by H. Wolfs and H. Grotowsky are reported and discussed. In addition to the usual constituents, pentosans and other members of the carbohydrate group were determined. On an average there was little difference between the dry-matter content of the artichokes harvested in the spring and fall.

The artichokes kept well and did not change much when stored for 3 or 4 months in a cellar though, generally speaking, there was a loss of water and a corresponding gain of dry material. The value of artichokes for the production of alcohol and this phase of the subject of artichoke raising are spoken of.

Consumption of fat in the Tropics, O. Effertz (*Wiener Klin. Wchnschr., 17 (1904), No. 2, p. 37; abs. in Zentbl. Physiol., 18 (1904), No. 3, p. 84*).—The author noted that large amounts of fat were eaten in tropical Central America and suggests reasons for this.

The natural oil foods, A. S. Atkinson (*What-to-Eat, 16 (1904), No. 6, p. 185*).—The author believes that vegetable oils are worthy of an important place in the diet.

The calcium and iron content of foods, G. von Bunge (*Ztschr. Biol., 45 (1904), No. 4, pp. 532–539*).—According to the author the only mineral constituents which might be deficient in the diet are calcium and iron. Ash analyses of foods are reported and others quoted for purposes of comparison, and the principal foods arranged according to their ash and calcium content, the largest amount of calcium oxid, 1,510 mg. per 100 gm. dry matter, being found in cow's milk, and the largest amount of iron, 340 mg. per 100 gm. dry matter, in hemoglobin.

The form in which mineral constituents, especially calcium, are assimilated is discussed. In the author's opinion it is doubtful if inorganic calcium salts as they occur in potable waters are absorbed and assimilated under all conditions.

The chemical composition of the inner part of the shell of the coffee bean, B. von Bittó (*Jour. Landw., 52 (1904), No. 1–2, pp. 93–95*).—Proximate and ash analyses are reported.

The work of the Elberfeld analytical laboratory for 1903, J. Heckmann and A. Lauffs (*Ber. Tät. Chem. Untersuchungs. Elberfeld, 1903; abs. in Hyg. Rundschau, 14 (1904), No. 10, pp. 475, 476*).—Among the data reported are analyses of a large number of samples of meat, butter, and other food products.

A swelling of canned peas accompanied by a malodorous decomposition, H. A. Harding and J. F. Nicholson (*New York State Sta. Bul. 249, pp. 153–168*).—Studies were undertaken of bacteria causing serious losses of canned peas at a cannery. In general the spoiled cans presented a bulged appearance, and in some cases they were blown open. The peas had a disagreeable odor suggesting hydrogen sulphid. They were mushy, the skins were inflated, and the liquor was darkened and of a greenish tinge, due to particles of the ruptured peas. A few of the spoiled cans (about 1 per cent) were but slightly swelled. In these the contents had an acid but not especially disagreeable odor and the appearance of the peas was normal, though the liquor was distinctly milky and possessed a sharp acid taste.

A microscopical examination of the juice showed that the cans in which the disagreeable odor was noticed all contained a rod form of bacteria, the spores of which survived the heat employed in processing the cans. This bacterium, which was studied in pure culture and described, was found to be the cause of the fermentation. Experiments show that the spores were destroyed on heating 2-lb. cans of peas at 240° F. (115 5/9° C.) for 30 minutes. When this method of processing was tested on a large scale at a factory the micro-organisms were destroyed without injuring the commercial quality of the goods.

A coccus form of bacteria was separated from the sour cans not characterized by a disagreeable odor and this was studied "sufficiently to show that it would not only sour cans of peas when artificially introduced but that when kept at blood heat these cans would commonly bulge."

A pea canners' problem solved, F. H. Hall, H. A. Harding, and J. F. Nicholson (*New York State Sta. Bul. 249, popular ed., pp. 7, fig. 1*).—A popular summary of the above bulletin.

Miscellaneous bacteriological investigations (*Wisconsin Sta. Rpt. 1903, pp. 241, 242*).—Two investigations which have been carried on at the station are summarized, namely, Gaseous Fermentations in the Canning Industry, by H. L. Russell (E. S. R., 8, p. 699) and "Sticky" or "Slimy" Bread and Its Causes, by H. L. Russell (E. S. R., 11, p. 565).

Food requirements and hunger, Meisl (*Klin. Ther. Wchnschr., 1903, No. 1–2; abs. in Ztschr. Diätet. u. Phys. Ther., 8 (1904), No. 2, p. 117*).—The reasons for the sensation of hunger and related topics are discussed.

Concerning diet in hot seasons and warm climates, Hirschfeld (*Deut. Med. Wchnschr., 1902, No. 38; abs. in Ztschr. Diätet. u. Phys. Ther., 7 (1904), No. 12, p. 694*).—According to the author meat is desired in smaller amounts than usual, and the diet should contain foods furnishing an abundance of fat and carbohydrates. In addition to vegetables, milk (especially canned cream) is recommended.

Experiments on the food of man, L. Grandeau (*Jour. Agr. Prat., n. ser., 7 (1904), No. 20, pp. 641, 642*).—Experiments with the respiration apparatus are discussed, particularly the classic experiments by J. Ranke.

Dietary studies in the James Millikin University, 1904 (*Decatur, Ill., 1904, pp. 36*).—In connection with class work in domestic science dietaries covering a period of one week were planned, the object being to supply a minimum of 4 oz. of protein and 3,000 calories of energy per man per day, the cost of the raw food not to exceed 25 cts. Of the 11 studies planned 10 were tested with families of professors, groups of students, or other persons doing light or moderate muscular work.

"While there was scrupulous care in the week's test to avoid waste, and 'left-overs' usually appeared again in some appetizing form or were used in the soup pot, no account was taken of the ordinary waste of a thrifty family—through desire to make as little trouble for the housekeeper as possible, and as little divergence from the ordinary routine, in the hope that a dietary study may be regarded as a simple affair, and one to be easily undertaken . . . The meals were enjoyed, and surprise was expressed that such acceptable food could be furnished for the money. In one case the family experimented on was unaware of the fact, and in every instance much less money was expended than usual."

The food question in health and in disease (*British Med. Jour., 1904, No. 2264, p. 1208*).—The importance of a knowledge of food requirements is briefly discussed and the need of a thorough knowledge of dietetics by medical practitioners is pointed out.

Concerning the red and white meat in the diet of patients with acute nephritis, A. Kuschnir (*Prakt. Wratsch., 1902, Nos. 44, 45, 47, 48, and 49; abs. in Ztschr. Diätet. u. Phys. Ther., 8 (1904), No. 1, p. 57*).—When red and white meat were compared no differences were observed in the quantity of urine excreted per day, or in the renal excretion of nitrogen, urea, uric acid and extractives.

Concerning the use of artificial meat extract as a food and condiment, A. Castiglioni, Jr. (*Wien. Med. Presse, 1903, Nos. 45, 46; abs. in Ztschr. Diätet. u. Phys. Ther., 8 (1904), No. 1, p. 54*).—The value of a commercial meat extract is discussed.

Practical cookbook, Henriette Davidis (*Milwaukee: C. N. Caspar Co. [1904], 2. ed.; rev. in Boston Cooking-School Mag., 9 (1904), No. 1, p. XIV*).—This volume is published with German and English text and is the second American edition.

The cookery of corn, Virgilia Purmort (*Iowa Agr., 4 (1904), No. 6, pp. 223–225*).—The food value of corn is discussed and the importance of soaking corn meal before it is used for bread making, etc., is spoken of.

Institution recipes, Emma Smedley (*Philadelphia: William F. Fell Co. [1904], pp. 124; rev. in Boston Cooking-School Mag., 9 (1904), No. 1, p. XIV*).—On the basis of laboratory experiments and practical experience the author has prepared a collection of recipes for use in schools, hospitals, and other institutions. The quantities given in the recipes will serve, with a few exceptions, 150 persons.

When is a banana ripe? (*British Med. Jour., 1904, No. 2265, pp. 1271, 1272*).—It is said that bananas are in the best condition for eating when they are so ripe that the skins show dark spots.

Boric acid in foods, J. Prescher (*Arch. Pharm., 242 (1904), No. 3, pp. 194–210*).—Different methods of estimating boric acid are compared and a method proposed in which it is determined as bor-phosphate, which is regarded as too complicated for the convenient use of food chemists, though it gives very accurate results. Joergensen's method is regarded as the most practicable.

Fish preserved with the natural taste retained, M. Henseval (*Trav. Sta. Recherches Pêche Maritime Ostende, 1903, pp. 33–37; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 7 (1904), No. 9, p. 555*).—According to the author, fish pickled for a short time and then processed in tins for one-half hour at one-half the usual atmospheric pressure retain their normal taste and aroma.

Foreign import tariffs on meat and meat products, 1903, F. H. Hitchcock (*U. S. Dept. Agr., Division of Foreign Markets Bul. 35, pp. 64*).—Data are presented in tabular form which show the tariff rates and regulations enforced by various foreign countries with respect to the importation of meat and meat products.

Concerning the calculation of the heat of combustion of nitrogenous organic compounds, P. Lemoult (*Compt. Rend. Acad. Sci. Paris, 138 (1904), No. 15, pp. 900–902*).—Formulas for use in calculating heat of combustion of nitrogenous materials are proposed and discussed.

New experiments on the physiological action of the proteoses, F. P. Underhill (*Amer. Jour. Physiol., 9 (1903), No. 6, pp. 345–373, dgms. 2; reprinted in Studies Rockefeller Inst. Med. Research, 1 (1904), Art. 24*).—Previously noted (E. S. R., 15, p. 704).

Urea and urein, W. O. Moor (*Ztschr. Biol., 45 (1904), No. 4, pp. 420–463, 540, 541*).—The investigations, which are reported and discussed at length, led the author to conclude that the principal nitrogenous body in human urine is not urea but a compound which closely resembles it in its behavior toward reagents, for which he proposes the name urein. Like urea it forms compounds with oxalic acid, mercuric nitrate, and mercuric chlorid; is soluble in water, absolute alcohol, alcohol and ether, and glycerin. It differs, however, from urea in that it reduces permanganate of potash; is oily in form, yellow in color; has a marked odor; and is only slightly soluble in amyl alcohol.

ANIMAL PRODUCTION.

Feeding stuffs (*Wisconsin Sta. Rpt. 1903, pp. 302–306*).—The work of the station regarding the composition and inspection of feeding stuffs is summarized. The articles included are as follows: Examination of Oil Meals, by F. W. Woll (E. S. R., 8, p. 712); Examination of Miscellaneous Fodders, by F. W. Woll (E. S. R., 8, p. 719); Analyses of Wild Prairie Hay, by F. W. Woll (E. S. R., 9, p. 577); Composition of Feeding Stuffs, by F. W. Woll (E. S. R., 9, p. 581); Analyses of Feeding Stuffs, by F. W. Woll (E. S. R., 12, p. 71); The Law Regulating the Sale and Analysis of Concentrated Feeding Stuffs in Wisconsin, by W. A. Henry (E. S. R., 13, p. 676); Concentrated Feeding Stuffs Licensed for Sale in Wisconsin, 1902, by F. W. Woll

(E. S. R., 13, p. 977); Licensed Commercial Fertilizers and Concentrated Feeding Stuffs, 1902, by F. W. Woll and A. Vivian (E. S. R., 14, pp. 235, 279); Licensed Commercial Feeding Stuffs, 1902, by F. W. Woll and G. A. Olson (E. S. R., 14, p. 790); Analyses of Licensed Commercial Feeding Stuffs, 1902, by F. W. Woll and G. A. Olson (E. S. R., 14, p. 1001); Concentrated Feeding Stuffs and Fertilizers Licensed for Sale in Wisconsin, 1903, by F. W. Woll (E. S. R., 10, pp. 954, 1002); Licensed Commercial Fertilizers and Feeding Stuffs, by F. W. Woll and G. A. Olson (E. S. R., 15, pp. 463, 498); Licensed Commercial Feeding Stuffs, 1903, by F. W. Woll and G. A. Olson (E. S. R., 15, p. 801); and Concentrated Feeding Stuffs and Fertilizers Licensed for Sale in Wisconsin, 1904, by F. W. Woll (E. S. R., 15, p. 993).

The fact is noted that in addition to the above a number of the station reports have contained miscellaneous analyses of feeding stuffs, and that a general discussion of the subject has also been published (E. S. R., 9, p. 581).

Licensed concentrated feeding stuffs, F. W. Woll and G. A. Olson (*Wisconsin Sta. Bul. 113, pp 13–17, 20–22*).—A list is given of the feeding stuffs licensed for sale in 1904 together with their guaranteed protein and fat content. The State feeding-stuff law is quoted and suggestions are made regarding the purchase of concentrated feeds.

Commercial feeding stuffs (*Connecticut State Sta. Rpt. 1903, pt. 5, pp. 371–427*).—The data reported have been noted from another publication (E. S. R., 15, p. 889).

The feeding value of rape and other succulent foods (*Wisconsin Sta. Rpt. 1903, pp. 46–55*).—The growth and uses of the rape crop are discussed and the station investigations which have to do with its feeding value are summarized and discussed, the articles included being Growth and Uses of the Rape Crop, by J. A. Craig (E. S. R., 10, pp. 741, 773, 781); Rape for Feeding Sheep, by J. A. Craig (E. S. R., 8, p. 327); Succulent and Dry Rations for Fattening Lambs, by J. A. Craig (E. S. R., 8, p. 715); Rape Versus Clover for Growing Pigs, by W. L. Carlyle (E. S. R., 11, p. 570; Rape Versus Clover for Pigs, by W. L. Carlyle (E. S. R., 12, p. 76); Feeding Value of Rape for Growing Pigs, by W. L. Carlyle (E. S. R., 13, p. 80); and The Feeding Value of Rape for Swine, by W. L. Carlyle (E. S. R., 13, p. 981).

Report on the relative effects of superphosphate and basic slag upon the feeding quality of swedes, J. W. Paterson (*West of Scotland Agr. Col. Rpt. 1901, pp. 45–51*).—It was found that 40 sheep fed Swedish turnips manured with basic slag gained 15 per cent more than an equal number similarly treated in every way except that they were fed Swedish turnips manured with superphosphates. The turnips were analyzed and "taking weight of dry turnip matter into consideration, the respective positions per acre were as 97 to 100." Considering both yield and feeding value, basic slag "produced the smaller but the more valuable crop."

The principal feeds and fodders available to Ontario farmers, G. E. Day (*Ontario Agr. and Expt. Union Rpt. 1903, pp. 42–50, dgm. 1*).—A paper with discussion dealing with the composition and feeding value of concentrated and coarse feeding stuffs.

Indian food grains and fodders; their chemical composition, II, J. W. Leather (*Agr. Ledger, 1903, No. 7 (Med. and Chem. Ser., No. 16), pp. 147–192 + III*).—Analyses are reported of a large number of samples of rice and other cereal grains, leguminous seeds, oil-bearing seeds, oil cakes, milling products, chaff, straw, and cereal and leguminous forage crops, fresh and cured.

Sarco-phosphoric acid as a constituent of the central nervous system, A. Panella (*Gior. R. Accad. Med. Torino, 1903; abs. in Zentbl. Physiol., 18 (1904), No. 4, p. 114*).—As shown by quantitative determinations, sarco-phosphoric acid is a constant constituent of the large and small brain of lambs, pigs, calves, rabbits, guinea pigs, chickens, cats, and dogs.

Some of the effects of excessive nutrition, J. H. Shepperd (*Proc. Soc. Prom. Agr. Sci., 1904, pp. 98–101*).—A consideration of data which is briefly summarized,

in the author's opinion, warrants the conclusion that "overnutrition stimulates development, induces a shorter growth period, reduces the degree of prolificacy, causes a finishing of the flesh in live stock, brings about earlier changes in the dentition of stock, and causes a delicacy of constitution and premature decay."

The effect of condiments upon digestibility, G. FINGERLING (*Jour. Landw., 52 (1904), No. 1–2, pp. 145, 146*).—Continuing earlier work (E. S. R., 15, p. 605), the author studied with sheep the effect of aromatic substances or condiments upon the digestibility of a basal ration. It is stated that the test covered 8 or 10 days, but experimental data are not reported. It appeared that fennel, fenugreek, and anise had no effect upon the digestibility of the basal ration, and from the work as a whole the general conclusion was drawn that condimental feeds do not induce rapid fattening of animals.

Report on experiments on the winter fattening of cattle, 1899–1900, J. W. PATERSON (*West of Scotland Agr. Col. Rpt. 1900, pp. 1–22*).—In this article, which was previously published as Bulletin No. 6 of the college, a full report is given of experiments noted from another publication (E. S. R., 12, p. 478).

Experiments on the fattening of cattle on pasture, 1901, J. W. PATERSON (*West of Scotland Agr. Col. Rpt. 1901, pp. 9–12*).—The relative feeding value of decorticated cotton-seed cake, alone and mixed with an equal quantity of corn meal, was studied with steers fattened on pasture. The greatest gains and the most profit were noted with the lots receiving the mixed-grain ration.

Report on experiments on the winter fattening of sheep, 1899–1900, J. W. PATERSON (*West of Scotland Agr. Col. Rpt. 1900, pp. 23–44*).—In a test of different concentrated feeds for sheep decorticated cotton-seed cake and maize 1:1 gave better results than linseed cake alone, or with oats or a mixture of linseed cake, oats, decorticated cotton-seed cake, and maize.

In the author's opinion the maize could be exchanged for oats in many cases with advantage. "Linseed cake alone, to supply concentrated food, is too laxative to succeed in a root diet. . . . Linseed cake is specially unsuited for animals requiring short keep. . . . A limited quantity of roots has a high value in sheep feeding. Hay or other fibrous food must be given along with them to regulate digestion."

In this test the comparative advantages of feeding under cover or out of doors were taken into account. According to the author, "house feeding is not to be recommended for periods less than 6 weeks. In longer periods the advantages depend upon the state of the weather and the kinds of food used. With a serious fall of temperature, or with excessive rainfall in the later periods, housing is an advantage with every food. It is of the greatest advantage with those foods which are of the most laxative character."

This article was previously published as Bulletin No. 7 of the college.

Experiments in lamb feeding (*Wisconsin Sta. Rpt. 1903, pp. 56–68*).—The station experiments on lamb feeding are summarized, the articles included being as follows: Grain Feeding Lambs for Market, by J. A. Craig (E. S. R., 8, pp. 332, 720); Farm Grains for Fattening Lambs, by J. A. Craig (E. S. R., 8, p. 714; 9, p. 578); Fall-Shearing Lambs Before Fattening, by J. A. Craig (E. S. R., 8, p. 329); Corn Meal, Bran and Oats for Lambs Before and After Weaning, by J. A. Craig (E. S. R., 8, p. 714); Grain for Lambs Before Weaning, by J. A. Craig (E. S. R., 10, p. 774); Farm Grains for Lambs Before and After Weaning, by W. L. Carlyle (E. S. R., 11, p. 567); Grain Mixture for Lambs Before and After Weaning, by J. A. Craig (E. S. R., 10, p. 775); and Feeding Ground Corn Versus Ground Peas to Lambs Before and After Weaning, by W. L. Carlyle (E. S. R., 12, p. 74).

Breeding lambs for market (*Wisconsin Sta. Rpt. 1903, pp. 69–73*).—The following investigations are summarized: Breeding Early Lambs, by J. A. Craig (E. S. R., 9, p. 328); Lambs for Early Spring Market, by J. A. Craig (E. S. R., 10, p. 775); and Influence of Breeding on the Feeding Qualities of Lambs, by J. A. Craig (E. S. R., 9, p. 577).

The flock and its management (*Wisconsin Sta. Rpt. 1903, pp. 74–81*).—The station experiments in sheep feeding, management, and related topics are summarized, the following articles being included: Establishing a Flock of Mutton Sheep, by J. A. Craig (E. S. R., 10, p. 776); Three Types of Market Sheep, by W. L. Carlyle (E. S. R., 14, p. 996); The Comparative Feeding Value of Corn Fodder, Corn Silage, Roots and Hay for Feeding Breeding Ewes in Winter, by W. L. Carlyle (E. S. R., 13, p. 77); The Comparative Value and the Effect Upon the Lamb Crop of Feeding Various Rations to Ewes in Winter, by W. L. Carlyle (E. S. R., 13, p. 978); The Comparative Value and Effect Upon the Lambs of Feeding Various Grain Rations to Pregnant Ewes, by W. L. Carlyle (E. S. R., 14, p. 996); Some Observations on Sheep Breeding from the Experiment Station Flock Records, by W. L. Carlyle and T. F. McConnell (E. S. R., 14, p. 996); and A Dipping Vat for Sheep, by J. A. Craig (E. S. R., 8, p. 720).

Fertility in sheep, F. H. A. MARSHALL (*Trans. Highland and Agr. Soc. Scotland, 5. ser., 16 (1904), pp. 34–43*).—From a consideration of the data regarding the fertility of ewes, the author believes that "the question of flushing and, what is closely related to it, the question of the causes producing follicular degeneration, require further investigation, must be generally admitted, and should, in fact, be emphasized. In the meantime, perhaps, the general practical conclusion to be drawn . . . is that it is better to keep breeding ewes in good thriving condition as continuously as possible than to submit them to a forced and rapid process of artificial stimulation at the tupping period, while maintaining them at other times of the year on mere sustenance diet. The consideration of the age of the ewe, as an important factor in determining the effects of flushing, should also not be neglected." Other topics relating to fertility are discussed.

Angora goats on an Iowa farm, B. W. CROSSLEY (*Iowa Agr., 4 (1904), No. 6, pp. 227–229*).—A brief account of experience with a flock of grade Angora goats, which the author considers successful. The goats were allowed the run of an open shed and were fed some corn in addition to the feed which they gathered.

The 100 does in the flock dropped 93 kids during April. In October the kids were weaned; the young does, 52 in number, were turned back with the flock, and the wethers were fattened, being given alfalfa hay with 1.5 bu. of corn for 84 days. They weighed 80 lbs. per head on an average and were sold for $4.85 per 100 lbs. At the end of 2 years the flock was sold and, according to the author, returned a satisfactory profit in addition to clearing up a considerable tract of land.

Some results in swine feeding, J. WITHYCOMBE (*Oregon Sta. Bul. 80, pp. 19, figs. 4*).—A number of experiments in which various feeding stuffs are compared are reported and discussed with special reference to the local pig-feeding industry.

In a study of the value of apples, 3 pigs about 8 months old were fed all the apples they would consume for 29 days. The total gain made was 41.5 lbs., 38.5 lbs. of which was made during the first 14 days of the test, and is attributed by the author to the filling up of the intestinal tract with succulent food or to the influence of previous feed. During this time the total amount of apples consumed was 2,016 lbs. The pigs remained in good health, "although during the last week they began to manifest symptoms of restlessness which were evidently expressions of hunger for a more nitrogenous diet.

"Hogs can not be expected to make a satisfactory growth upon apples alone, as they contain but a small percentage of muscle-forming material. However, if some nitrogenous supplementary feed were fed, doubtless the apples would have given better results."

Apples, whole and cut clover silage, and pea silage were compared as a maintenance ration with brood sows, the clover silage being supplemented during one period by wheat chop and skim-milk. According to the author the test showed that the clover silage for mature hogs is slightly better than a maintenance ration and that

"64.3 lbs. of apples will not only maintain a matured hog in good condition, but enable it to add 1 lb. to its live weight. The experiment also indicates that a ration of 1 lb. of crushed wheat, 2 lbs. of skim milk, and 6.66 lbs. of clover silage fed to a brood sow weighing 300 lbs. or over will keep her in good condition when not suckling pigs."

The value of clover pasture for growing pigs was tested with 12 animals about 3 months old, hurdled on 26 sq. rods of good clover pasturage. In 3 months there was a total gain of 253 lbs. According to the author, "one acre of good clover for growing hogs represents a value of $44.36."

As regards the value of rape, 10 young pigs gained 154 lbs. when turned on an acre of June sown rape for 42 days and kept in a thriving healthy condition, although they received no other feed.

A thrifty barrow fed, in a pen, rape, vetch, skim milk, and a little grain gained 184 lbs. in 70 days, requiring 3.19 lbs. of crushed wheat and 1.52 lbs. of skim milk in addition to the green feed for a pound of gain.

The value of soiling matured pigs was studied with a lot of 4. In 1 month they made a total gain of 25 lbs., requiring 85.48 lbs. of green feed and 1.36 lbs. of mixed grain per pound of gain. The soiling crops fed were rape, crimson clover, and alfalfa. During the next month they were fed green alfalfa only and made a total gain of 5 lbs., requiring 328.4 lbs. of the green feed to produce a pound of gain. In the author's opinion better results would have been obtained had the pigs been pastured on alfalfa.

In a second test 16 young pigs were fed from May 1 to June 2 crimson clover and alfalfa, with skim milk and crushed wheat. The total gain made was 221 lbs. and the feed required per pound of gain 15.85 lbs. skim milk, 7.66 lbs. of the soiling crop, and 0.34 lb. grain.

Supplementing a ration of green feed and skim milk with grain was studied with 2 lots of 8 pigs each. On alfalfa and skim milk the total gain made in 30 days was 130 lbs. On skim milk and alfalfa supplemented by crushed wheat the total gain was 125 lbs. The lot fed the grain was somewhat superior to the other lot as regards appearance and this, in the author's opinion, constituted the only advantage of the grain ration.

The feeding value of a mixture of peas and barley was tested with 3 pigs for a period covering 92 days, "which is about 30 days longer than is usually advisable to feed for economical results." The total gain made was 475 lbs., 7.1 lbs. of grain being required per pound of gain.

Six tests with an aggregate of 28 pigs of mixed breeding and various ages are reported in which wheat, whole and ground, alone and as part of a mixed ration, was studied, as well as the comparative value of wheat, peas, corn, barley, and barley and potatoes. Skim milk was also fed in some cases.

According to the author the best results were obtained with wheat, 4.48 lbs. being required on an average to produce a pound of gain. In the first half of the fattening period 3.81 lbs. was required per pound of gain, as compared with 5.12 lbs. in the last half. In other words, "the heavily larded hog resultant from a long period of feeding is much more costly to produce than the block hog, or the bacon type. . . . Results also indicate that a bushel of wheat properly fed to reasonably well-bred hogs should produce approximately 13.5 lbs. of live pork."

Tests on the comparative value of boiled clover hay and clover silage and cooked and uncooked grain have been noted from another publication (E. S. R., 13, p. 680).

Feeding trials with pigs (*Wisconsin Sta. Rpt. 1903, pp. 82–91*).—The following experiments on the feeding and management of pigs are summarized and discussed: Feeding Pigs for the Production of Lean and Fat Meat, by W. L. Carlyle (E. S. R., 13, p. 78); Effect of Feeding Various Grain Rations to Growing and Fattening Hogs,

by W. L. Carlyle and T. F. McConnell (E. S. R., 13, p. 979); The Result of a Feeding Trial to Determine the Comparative Effect of Feeding Pigs Rations of Corn Meal and of Ground Peas, by W. L. Carlyle (E. S. R., 13, p. 980); Results of an Experiment to Determine the Comparative Effect upon the Growth, Development, and Character of the Carcass of Pigs Fed upon Rations of Ground Peas and Corn Meal, by W. L. Carlyle and T. F. McConnell (E. S. R., 14, p. 999); The Result of a Feeding Trial Comparing Razorback with Cross-Bred Razorback and Improved Breeds of Hogs, by W. L. Carlyle (E. S. R., 14, p. 1000); and Canker Sore Mouth in Young Pigs, by W. L. Carlyle.

It is stated that the most important feature of these investigations was the experiments undertaken to determine the relative value of different rations for the production of fat and lean, since the market demands pork with a large percentage of lean meat. Rations with a high protein content, it is stated, were more conducive to the development of the internal organs of the pigs than the rations low in protein, and also to a distribution of a greater amount of lean with the fat in the carcasses.

Whole corn compared with corn meal for fattening pigs, W. A. Henry (*Wisconsin Sta. Rpt. 1903, pp. 43–45*).—Experiments previously reported (E. S. R., 14, p. 999) on the comparative value of whole and ground corn for fattening pigs are summarized. On an average 105 pigs required 5.16 lbs. of feed per pound of gain on a ration of dry shelled corn and middlings, as compared with 4.8 lbs. required by an equal number on a ration of corn meal and middlings.

In other words, there was "a saving of 36 lbs. of feed for each 100 lbs. of gain made by the hogs. This shows a gain by grinding the corn to meal of 6.9 per cent, or, say, 7 per cent in round numbers. While the direct advantage from grinding corn to meal was about 7 per cent, in these experiments there was a second advantage secured in that the hogs getting corn meal made more rapid gains than those fed shelled corn."

Feeding draft horses for the market, J. W. Coverdale (*Iowa Agr., 4 (1904), No. 6, pp. 238–240*).—On the basis of experience the author considers that the essential points in feeding draft horses for the market are "the selection for type and constitutional vigor, the careful starting on grains, the ration at full feed, toning up of his system, the place in which he is fed, the care of the stable, the grooming, exercise and training before selling." A corn ration is recommended at first, with a little oats once a day with a sprinkling of bran, and later these feeds in increasing amounts.

"Corn had best be given in the ear by itself. It may be fed morning and evening. A handful of flax meal should be fed just after watering in the morning. Oats and bran mixed make a good feed for dinner. The amount of each feed should be according to the appetite of the horse. Some horses eat more than others. However, a heavy horse on full feed will eat about 18 ears of corn twice a day; 15 qt. of oats and bran mixed, and about 10 lbs. of hay." The hay, it is said, should be given in small amounts 5 times per day.

Poultry experiments, C. Curtice (*Rhode Island Sta. Rpt. 1903, pp. 269–273*).—During the year the poultry work of the station has been principally with the incubation and brooding of chickens. In the incubation experiments 8,677 eggs have been set in incubators. Of these, 83 per cent were fertile, and 46 per cent of the fertile eggs, or 38.6 per cent of the total number of eggs, hatched, the efficiency of hatching under various conditions ranging from 0 to 84 per cent.

Owing to unfavorable circumstances the brooding experiments were not considered satisfactory. "The results have varied from 100 per cent downward." The other poultry work at the station and plans for future studies are very briefly spoken of.

Cooperative experiments in poultry raising, W. R. Graham (*Ontario Agr. and Expt. Union Rpt. 1903, pp. 40–42*).—A brief account with discussion of cooperative experiments on hatching chickens with incubators.

Poultry keeping for farmers, A. M. PRAIN (*Trans. Highland and Agr. Soc. Scotland, 5. ser., 16 (1904), pp. 62–74, figs. 12*).—Breeds of poultry, feeding, marketing, testing eggs, housing, and other topics are discussed.

DAIRY FARMING—DAIRYING.

Distillery and brewery by-products, J. B. LINDSEY (*Massachusetts Sta. Bul. 94, pp. 28, fig. 1*).—Distillers' grains, brewers' grains, and malt sprouts are described, and digestion and feeding experiments with these products are reported.

The dried distillers' grains used in the experiments showed the following composition: Water 9.75, ash 1.54, protein 35.36, fiber 12.97, extract matter 29.74, and fat 10.64 per cent. The coefficients of digestibility, as determined in experiments with sheep, were as follows: Dry matter 73, protein 71, fiber 77, extract matter 70, and fat 95 per cent. The average composition and digestibility of a number of samples are also given.

In an experiment with 6 cows, lasting 12 weeks, the distillers' grains were compared with Buffalo gluten feed. The gain in live weight of the cows and the yield of milk and butter were slightly in favor of the distillers' grains, though the differences were not large. The cost of food was also in favor of the distillers' grains. When the cows were fed the gluten meal, from 4 to 6 per cent more dry matter and from 7 to 9 per cent more digestible matter were required to produce milk, solids, and fat than when distillers' grains were fed. Distillers' grains are, therefore, believed to be fully equal, if not superior, to gluten feed in nutritive value, and without injurious effect on the health of the animals.

No objectionable flavor or odor was detected in the milk of cows fed distillers' grains, and neither was the keeping quality of the milk apparently affected in any way. The chief use of distillers' grains is for dairy cows, and for this purpose 2 to 4 lbs. mixed with other grains may be fed daily. Several combinations are suggested.

The dried brewers' grains used showed the following composition: Water 14.06, ash 3.22, protein 23.26, fiber 14.58, extract matter 38.82, and fat 6.06 per cent; and the following coefficients of digestibility: Dry matter 61, protein 82, fiber 47, extract matter 56, and fat 88 per cent. Average analyses and digestibility are also reported.

This material was compared with wheat bran in a feeding experiment with 8 cows. The gain in live weight and yield of milk was slightly in favor of the brewers' grains. The ration containing brewers' grains was slightly more economical. Very little difference was observed in the dry matter and digestible matter required to produce solids and fat. As before, the brewers' grains exerted no unfavorable influence on the flavor and keeping quality of the milk. In feeding brewers' grains to dairy cows it is believed to be preferable to mix them with other grains, and to feed from 2 to 5 lbs. daily. Several rations are suggested. Notes are also given on feeding wet brewers' grains. It is believed 25 lbs. is a fair daily allowance for average sized cows.

The malt sprouts tested showed the following composition: Water 10.68, ash 4.40, protein 25.33, fiber 14.57, extract matter 43.96, and fat 1.06 per cent; and the following coefficients of digestibility, as determined in experiments with sheep: Dry matter 78, protein 76, fiber 102, extract matter 78, and fat 60 per cent.

This material was compared with gluten feed in an experiment with 4 cows, lasting 6 weeks. The gain in live weight and the yield of milk were slightly in favor of the gluten feed. It is believed that malt sprouts may constitute one-third of the daily grain ration, and at the price usually asked may be regarded as an economical feeding stuff. Several rations are suggested.

The following general statements are made concerning the relative value of the several feeding stuffs:

"Distillers' dried grains with 32 per cent or more protein are fully equal if not rather superior to gluten feed in feeding value. Distillers' grains and gluten feed

are worth fully one-half as much again as wheat bran. Brewers' dried grains and malt sprouts do not vary greatly in feeding value; the former will generally be given the preference. Brewers' grains and malt sprouts are rather superior in feeding value to wheat bran, probably 10 per cent."

Records of a dairy herd for five years, C. L. BEACH (*Connecticut Storrs Sta. Bul. 29, pp. 32, figs. 18*).—Individual records are given of 17 to 25 cows each year for 5 years. In all, records were obtained of 50 different cows, the total number of lactation periods being 103. The average annual production of milk for the 5 years was 5,498 lbs., and the average production of butter 326 lbs. The kind and amount of food was much the same during the entire period. The increase in the net profits from a loss of $1.23 in 1899 to a profit of $21.69 per cow in 1903 is attributed to the selection of animals better suited to dairy purposes.

The cows were classified as regards type into the dairy group, cows lacking digestive capacity, and the fleshy group, the average profits of the 3 types being, respectively, $28.09, $5.81, and $6.09. As regards the profits from butter fat, the Jerseys made the best showing; but as regards the profits from milk, a much better record was made by the Holstein breed. On an average the maximum yield of milk was obtained during the third week of lactation. The fat content of the milk increased about 0.1 per cent each month during the first 10 months of lactation.

Experiments in feeding and management of dairy cows (*Wisconsin Sta. Rpt. 1903, pp. 92–105*).—This is a summary of the following articles previously published by the station: One Hundred American Rations for Dairy Cows, by F. W. Woll (E. S. R., 5, p. 884); On the Comparative Value of Linseed Meal, Corn Meal, and Wheat Bran for Milch Cows, by F. W. Woll (E. S. R., 8, p. 335); On the Economy of Heavy Grain Feeding of Dairy Cows, I, by F. W. Woll and W. L. Carlyle (E. S. R., 12, p. 81); On the Economy of Heavy Grain Feeding of Dairy Cows, II, by F. W. Woll and W. L. Carlyle (E. S. R., 13, p. 80); Dairy Herd Record, by W. L. Carlyle (E. S. R., 12, p. 83); Record of the University Dairy Herd, by W. L. Carlyle (E. S. R., 13, p. 81); Studies in Milk Production, by W. L. Carlyle (E. S. R., 15, p. 502); The Effect on Dairy Cows of Changing Milkers, by W. L. Carlyle (E. S. R., 12, p. 83), and Protecting Cows from Flies, by W. L. Carlyle (E. S. R., 12, p. 82).

Tests of dairy cows (*Wisconsin Sta. Rpt. 1903, pp. 114–117*).—This is a summary of the following articles, previously published by the station: Tests of the Guernsey Cow Suke of Rosendale (6520 G. H. B.), by F. W. Woll (E. S. R., 10, p. 782); Tests of Dairy Cows, by J. W. Decker (E. S. R., 8, p. 336; 11, p. 587); Tests of Dairy Cows, 1898–99, by J. W. Decker (E. S. R., 12, p. 90); Official Tests of Dairy Cows, 1899–1900, by F. W. Woll (E. S. R., 13, p. 81); Official Tests of Dairy Cows, 1900–1901, by F. W. Woll and R. H. Shaw (E. S. R., 13, p. 986); Official Tests of Dairy Cows, 1901–2, by F. W. Woll (E. S. R., 14, p. 1007), and Official Tests of Dairy Cows, 1902–3, by F. W. Woll (E. S. R., 15, p. 1000).

Testing cows at the farm (*Wisconsin Sta. Rpt. 1903, pp. 106–113*).—This is a summary of two articles by E. H. Farrington entitled: Annual Milk and Butter Production of Cows Owned by Patrons of the University Creamery (E. S. R., 13, p. 985), and Testing Cows at the Farm (E. S. R., 11, p. 673).

Dairy observations, C. L. BEACH (*Connecticut Storrs Sta. Bul. 28, pp. 20, figs. 7*).—This consists of reprints of 3 articles from the last annual report, namely, Dehorning Cattle (E. S. R., 15, p. 905), Milking Records (E. S. R., 15, p. 905), and the Food Cost of Raising Calves (E. S. R., 15, p. 893).

Standard milk, F. W. MORSE (*New Hampshire Sta. Bul. 103, pp. 79–82*).—This is a brief discussion of the composition of milk with special reference to the requirements of the New Hampshire law, which is quoted. As a means of meeting the requirements of the law the careful selection and testing of cows is urged. To aid farmers in this respect the station offers to make determinations of fat for 10 cts. per sample, and total solids for 25 cts. per sample. Brief directions are given for sampling.

Determinations of the fat content of milk produced by cows of different breeds, R. GRIPENBERG (*Landtbr. Styr. Meddel. [Helsingfors], 1903, No. 44, pp. 36–52, 57–63, 81–94*).—These investigations were conducted with pure-bred cows of the Ayrshire, Holstein, and Finnish breeds, together with some cross-bred cows, for a period of 5 years, 1896–1900. Tabular statements of the fat determinations are given, and the results are briefly discussed.—F. W. WOLL.

Milk, G. TIMEUS (*Abs. in Chem. Centbl., 1904, I, No. 3, p. 202*).—Milk hygiene is discussed with special reference to the feeding of infants. It is reported that in Trieste analyses of market milk made during a period of 3 years showed that more or less cream had been removed from 78 per cent of the samples examined, and that some samples contained only 0.5 per cent of fat.

The animal odor and the aromatic substances in milk, J. E. HAUGAN (*Landmandsblade, 37 (1904), No. 5, pp. 66–69*).

On the principal micro-organisms in milk and their importance in dairying, E. PETERSSON (*Nord. Mejeri Tidn., 19 (1904), No. 20, pp. 267–269*).

On "Buddeizing" of milk (*Nord. Mejeri Tidn., 19 (1904), No. 10, pp. 123–128*).—Refers to the method of preserving milk by means of hydrogen peroxid, proposed by Budde (E. S. R., 14, p. 1005). Hygienic and therapeutic properties are claimed for the milk preserved by this method.—F. W. WOLL.

Investigations of the relation between the specific gravity and fat content of the cream and the yield of butter obtained from the same, R. GRIPENBERG (*Landtbr. Styr. Meddel. [Helsingfors], 1903, No. 44, pp. 63–81*).—The method of payment of cream delivered to creameries according to volume or weight is not found sufficiently correct on account of the large variations in the fat content of the cream.

The author discusses the various factors that influence the concentration of the cream, and gives the results of trials showing that even in creameries where the separator is run by a well-regulated steam engine furnishing ample power, the fat content of the cream will vary between 16 and 26 per cent. In 78 per cent of the observations made the fat content varied between 19 and 24 per cent. The author recommends weighing the cream in making Babcock tests, and by means of a simple formula calculates the yield of butter from certain quantities of cream of different richness, and the price to be paid for the same, with the price of butter ranging between ordinary limits.

The following table shows the relation between the specific gravity of the cream at 15 and 60° C., the percentage of fat in the cream, and the yield of butter per 100 kilograms of cream:

Yield of butter in relation to specific gravity and fat content of cream.

Specific gravity of cream.		Per cent fat in cream.	Kg. butter from 100 kilos cream.
15° C.	60° C.		
1.0160	0.9955	17.5	21.1
1.0154	.9948	18.0	21.3
1.0146	.9940	18.5	21.9
1.0143	.9934	19.0	22.6
1.0140	.9928	19.5	23.4
1.0135	.9923	20.0	23.9
1.0131	.9915	20.5	24.4
1.0127	.9912	21.0	24.8
1.0123	.9906	21.5	25.2
1.0120	.9903	22.0	25.7
1.0116	.9901	22.5	26.2
1.0112	.9890	23.0	26.9
1.0107	.9881	23.5	27.5
1.0104	.9878	24.0	27.8
1.0100	.9875	24.5	27.9

—F. W. WOLL.

Experiments with the "Radiator," R. GRIPENBERG (*Landtbr. Styr. Meddel.* [*Helsingfors*], *1903*, *No. 44*, *pp. 52-57*).—The construction of this combined cream separator and churn is described, and the results of comparative trials with the radiator and with separators and churns are given, showing that the yield of butter is nearly the same in both cases.—F. W. WOLL.

Preservation of milk for direct use by pasteurization (*Wisconsin Sta. Rpt. 1903*, *pp. 177-182*).—This is a summary of the following articles previously published by the station: Pasteurization of Milk and Cream for Direct Consumption, by H. L. Russell (E. S. R., 7, p. 987); Bacteriological Investigations on Pasteurized Milk and Cream, H. L. Russell (E. S. R., 8, p. 722); Pasteurization of Milk and Cream at 140° F., by E. H. Farrington and H. L. Russell (E. S. R., 12, p. 84); Thermal Death Point of Tubercle Bacilli under Commercial Conditions, by H. L. Russell and E. G. Hastings (E. S. R., 13, p. 83), and Increased Resistance of Bacteria in Milk Pasteurized in Contact with Air, by H. L. Russell and E. G. Hastings (E. S. R., 13, p. 986).

Conditions affecting the consistency of milk; means of restoring consistency of pasteurized cream (*Wisconsin Sta. Rpt. 1903*, *pp. 183-187*, *figs. 2*).—This is a summary of the following articles previously published by the station: Effect of Pasteurization and Sterilization on the Viscosity and Fat Globules of Milk and Cream, by F. W. Woll (E. S. R., 8, p. 723); Conditions Affecting the Consistency of Milk, by S. M. Babcock and H. L. Russell (E. S. R., 9, p. 582); Restoration of the Consistency of Pasteurized Milk and Cream, by S. M. Babcock and H. L. Russell (E. S. R., 9, p. 583), and Restoration of the Consistency of Pasteurized Cream, by S. M. Babcock and H. L. Russell (E. S. R., 9, p. 181).

Dairy bacteriological problems (*Wisconsin Sta. Rpt. 1903*, *pp. 231-240*, *figs. 2*).—This is a summary of the following articles previously published by the station: Sources of Bacterial Contamination of Milk, by H. L. Russell (E. S. R., 8, p. 340); Relative Absorption of Odors in Warm and Cold Milk, by H. L. Russell (E. S. R., 11, p. 581); Tainted or Defective Milks; Their Causes and Methods of Prevention, by H. L. Russell (E. S. R., 9, p. 990), and Influence of Sugar on Nature of Fermentations in Milk and Cheese, by S. M. Babcock, H. L. Russell, A. Vivian, and E. G. Hastings (E. S. R., 13, p. 989).

Galactase, the inherent digestive enzym of milk (*Wisconsin Sta. Rpt. 1903*, *pp. 201-205*).—This is essentially a summary of the following articles previously published by the station: Unorganized Ferments of Milk; a New Factor in Cheese Ripening, by S. M. Babcock and H. L. Russell (E. S. R., 10, p. 785); Properties of Galactase, a Digestive Ferment of Milk, by S. M. Babcock, H. L. Russell, and A. Vivian (E. S. R., 11, p. 578); Distribution of Galactase in Cow's Milk, by S. M. Babcock, H. L. Russell, and A. Vivian (E. S. R., 11, p. 579); Distribution of Galactase in Milk of Different Species of Mammalia, by S. M. Babcock, H. L. Russell, and A. Vivian (E. S. R., 11, p. 579), and Action of Proteolytic Ferments on Milk with Special Reference to Galactase, the Cheese-Ripening Enzym, by S. M. Babcock, H. L. Russell, and A. Vivian (E. S. R., 12, p. 87).

Methods and apparatus for testing milk and milk products (*Wisconsin Sta. Rpt. 1903*, *pp. 118-182*, *pls. 3*, *figs. 8*).—Numerous articles previously published by the station are summarized under the following subheadings:

The Babcock milk test (pp. 118-131).—A Comparison of the Babcock Test and the Gravimetric Method of Estimating Fat in Skim Milk, by E. H. Farrington (E. S. R., 9, p. 589); A Source of Error in Some Turbine Testers, by F. W. Woll (E. S. R., 13, p. 83); Influence of Temperature on Test of Skim Milk by Babcock Test, by E. H. Farrington (E. S. R., 13, p. 83); Estimation of Fat in Sweetened Condensed Milk by Babcock Test, by E. H. Farrington (E. S. R., 13, p. 83); Calculating Dividends for Milk and for Cream at the Same Factory, by E. H. Farrington (E. S. R., 13, p. 84); The Trowbridge Method of Calibrating Babcock Test Bottles, by E. H.

Farrington (E. S. R., 13, p. 986), and A Modified Cream Test Bottle, by E. H. Farrington (E. S. R., 14, p. 1010).

Wisconsin curd test (pp. 132–134).—Factory Tests for Milk, by S. M. Babcock, H. L. Russell, and J. W. Decker (E. S. R., 10, p. 385), and Improved Curd Test for Detection of Tainted Milks, by S. M. Babcock, H. L. Russell, and J. W. Decker (E. S. R., 11, p. 599).

Alkaline tablet test (pp. 134–142).—Alkaline Tablet Test of Acidity in Milk and Cream, by E. H. Farrington (E. S. R., 8, p. 933; 9, p. 589).

Investigation of creamery problems (pp. 143–156).—Effect of Salt on the Water Contents of Buttĕr, by E. H. Farrington (E. S. R., 12, p. 86); White Spots on Butter, by E. H. Farrington (E. S. R., 12, p. 87); Pasteurization of Skim Milk, by E. H. Farrington (E. S. R., 12, p. 85); Columbia Air Churn, by E. H. Farrington and F. Dewhirst (E. S. R., 13, p. 84); Composition of Frozen Milk, by E. H. Farrington (E. S. R., 14, p. 1010); Score of Butter as Affected by Size of Package, by E. H. Farrington (E. S. R., 11, p. 599); Difficulties in the Way of Drawing Conclusions from Scores of Butter When Based on One Judge's Scores, by E. H. Farrington (E. S. R., 14, p. 1011), and Power Tests of Cream Separators, by A. W. Richter (E. S. R., 8, pp. 170, 732).

Miscellaneous dairy investigations (pp. 156–165).—The Fat Globules in Cows' Milk, by F. W. Woll (E. S. R., 8, p. 337); On the Average Composition of Milk of Pure-Bred Cows of Different Breeds, by F. W. Woll (E. S. R., 13, p. 985); Investigations of Methods of Milking, by F. W. Woll (E. S. R., 14, pp. 694, 1007); Examination of Dairy Salt, by F. W. Woll (E. S. R., 11, p. 585; 12, p. 91); A Composite Milk Sampling Pipette, by J. W. Decker (E. S. R., 12, p. 91); A Comparison of Reagents for Milk Proteids, with some Notes on the Kjeldahl Method of N Determinations, by A. Vivian (E. S. R., 12, p. 19), and A Rapid Method of Estimating Salt in Butter, by A. Vivian (E. S. R., 13, p. 16).

Statistical investigations relating to the dairy industry (pp. 165, 166).—Statistics from 52 Wisconsin Separator Creameries, by E. H. Farrington (E. S. R., 9, p. 286; 10, p. 792); Statistical Data Relative to the Cheese Industry of Wisconsin, by J. W. Decker (E. S. R., 10, p. 790); Distribution of Cheese Factories in Wisconsin, by S. M. Babcock, H. L. Russell, and J. W. Decker (E. S. R., 10, p. 792); The Cheese Industry: Its Development and Possibilities in Wisconsin, by S. M. Babcock and H. L. Russell (E. S. R., 9, p. 387), and The Dairy Industry in Wisconsin with Wall Map Showing Distribution of Creameries and Cheese Factories in 1901, by H. L. Russell (E. S. R., 13, p. 690).

The fat testing of cream by the Babcock method, E. H. WEBSTER (*U. S. Dept. Agr., Bureau of Animal Industry Bul. 58, pp. 29, pls. 2, fig. 1*).—Investigations in creameries in several western States revealed, according to the author, some surprising facts in regard to the general practice of handling the Babcock method in cream testing.

"Men who used the test daily were found to be at fault in many particulars, and in some instances not the first idea of the principle underlying the method seemed to be in the mind of the operator." This is attributed in part to carelessness on the part of the operator, and in part to improper instruction given for the use of the Babcock test as applied to cream.

This bulletin describes the manipulation of the test in detail, including the results of original tests, notes concerning faults which have been observed, and suggestions as to better methods. The three vital points in making the test, (1) a true sample of the cream to be tested, (2) an exact quantity of the sample in the test bottle, and (3) reading the test accurately, are described in the order mentioned, and condensed directions for making fat tests of cream are presented in the form of a summary to the bulletin.

Pasteurization as applied to butter making (*Wisconsin Sta. Rpt. 1903, pp. 167-176*).—This is a summary of the following articles previously published by the station: Use of Bacterial Culture Starters in Butter Making with Especial Reference to the Conn Culture (B41), by E. H. Farrington and H. L. Russell (E. S. R., 8, p. 732); The Conn Culture (B41) in Butter Making, by E. H. Farrington and H. L. Russell (E. S. R., 8, p. 261); Pasteurization Experiments in Butter Making, by E. H. Farrington and H. L. Russell (E. S. R., 10, p. 889; 11, p. 599), and Pasteurized Cream Butter, by E. H. Farrington and J. H. Godfrey (E. S. R., 14, p. 1011).

"During the past year it has been shown that sour cream may be successfully pasteurized, and at the present time there are indications that unless the sour cream contains over 30 per cent fat the pasteurizing of it brings about conditions by which a rich buttermilk is obtained when such cream is churned. A rich, sour cream may be pasteurized and churned without an excessive loss of butter in the buttermilk, but a thin, sour cream containing in the neighborhood of 20 per cent fat, when pasteurized and churned sometimes leaves too much fat in the buttermilk, and on this account may diminish the yield of butter somewhat. A further investigation of this point in regard to the pasteurization of sour cream is very much needed."

A brief history of butter production in Denmark, M. P. BLEM (*Mälkeritid., 16 (1903), No. 52, pp. 919-925*).

Final report of the committee on butter regulations, H. C. PLUNKETT ET AL. (*London: Wyman & Sons, Ltd., 1903, pp. 28*).—This committee, consisting of 10 members, was appointed by the Board of Agriculture and the Department of Agriculture and other Industries, and Technical Instruction for Ireland, for the purpose of determining what deficiency in any of the normal constituents of butter, or what addition of extraneous matter, or what proportion of water in any sample of butter shall, for the purpose of the Sale of Food and Drugs Acts, raise a presumption, until the contrary is proved, that the butter is not genuine.

In a previous report the adoption of the limit of 16 per cent of water was recommended. In the present report it is recommended (1) "That the figure 24 arrived at by the Reichert-Wollny method should be the limit below which a presumption should be raised that butter is not genuine; (2) that the use of 10 per cent of sesame oil in the manufacture of margarin be made compulsory; and (3) that steps should be taken to obtain international cooperation." Appended to the report are notes of reservation of several members of the committee, and also a description of the Reichert-Wollny method.

The minutes of evidence presented to this committee, and upon which this report is based, have been published in a separate volume of 660 pages.

Special series of cheese bulletins (*Wisconsin Sta. Rpt. 1903, pp. 220-225, fig. 1*).—This is a summary of the following bulletins of the station: The Cheese Industry: Its Development and Possibilities in Wisconsin, by S. M. Babcock and H. L. Russell (E. S. R., 9, p. 387); The Constitution of Milk with Especial Reference to Cheese Production, by S. M. Babcock (E. S. R., 9, p. 888); Tainted or Defective Milks: Their Causes and Methods of Prevention, by H. L. Russell (E. S. R., 9, p. 990); Factory Tests for Milk, by S. M. Babcock, H. L. Russell, and J. W. Decker (E. S. R., 10, p. 385); Construction of Cheese Curing Rooms for Maintaining Temperatures of 58 to 68° F., by F. H. King (E. S. R., 11, p. 186); Dairy Industry in Wisconsin, with wall map, by H. L. Russell (E. S. R., 13, p. 690); Curing of Cheddar Cheese with Especial Reference to Cold Curing, by S. M. Babcock and H. L. Russell (E. S. R., 14, p. 490); Consolidated Cheese Curing Stations, by S. M. Babcock and H. L. Russell (E. S. R., 14, p. 490), and Shrinkage of Cold Cured Cheese During Ripening, by S. M. Babcock, H. L. Russell, and U. S. Baer (E. S. R., 15, p. 509).

Experimental work on methods of cheese manufacture (*Wisconsin Sta. Rpt. 1903, pp. 188-192, fig. 1*).—This is a summary of the following articles previously published by the station: Effect of Aeration on Flavor of Tainted Curds in Cheese

Making, by H. L. Russell (E. S. R., 8, p. 728); Influence of Acid on Texture of Cheese, by H. L. Russell and J. W. Decker (E. S. R., 8, p. 728); Hot-Iron Test, by S. M. Babcock (E. S. R., 8, p. 728); Albumen Cheese, by S. M. Babcock (E. S. R., 8, p. 728); Print Cheese, by E. H. Farrington (E. S. R., 13, p. 990); Ripening Milk Before Setting, by J. W. Decker (E. S. R., 8, p. 730); Effect of Varying Strengths of Rennet in Curdling Milk, by J. W. Decker (E. S. R., 11, p. 580); Action of Rennet in Watered Milk, by J. W. Decker (E. S. R., 11, p. 581); Action of Common Salt on Rennet Action, by J. W. Decker (E. S. R., 11, p. 584); Effect of Salt upon Cheese, by J. W. Decker (E. S. R., 8, p. 342), and Methods of Handling Sour Milk in Making Cheese, by J. W. Decker (E. S. R., 11, p. 585).

Bacteriology of cheese (*Wisconsin Sta. Rpt. 1903, pp. 226–230*).—This is a summary of the following articles: Gas-Producing Bacteria and Their Relation to Cheese, by H. L. Russell (E. S. R., 8, p. 730); Rise and Fall of Bacteria in Cheddar Cheese, by H. L. Russell (E. S. R., 9, p. 586); Pure Lactic Acid Cultures in Cheese Making, by H. L. Russell (E. S. R., 9, p. 587), and Effect of Digesting Bacteria on Cheese Solids, by H. L. Russell and V. H. Bassett (E. S. R., 12, p. 89).

Investigations regarding the curing of cheese (*Wisconsin Sta. Rpt. 1903, pp. 193–200*).—This contains a summary of the following articles previously published by the station: Unorganized Ferments of Milk; a New Factor in Cheese Ripening, by S. M. Babcock and H. L. Russell (E. S. R., 10, p. 785); Action of Proteolytic Ferments on Milk with Special Reference to Galactase, the Cheese-Ripening Enzym, by S. M. Babcock, H. L. Russell, A. Vivian, and E. G. Hastings (E. S. R., 12, p. 87); Influence of Galactase on Ripening of Cottage Cheese, by S. M. Babcock, H. L. Russell, and A. Vivian (E. S. R., 12, p. 88); Influence of Rennet on Cheese Ripening, by S. M. Babcock, H. L. Russell, and A. Vivian (E. S. R., 13, p. 87), and Influence of Varying Quantities of Rennet on Cold Cured Cheese, by S. M. Babcock, H. L. Russell, A. Vivian, and U. S. Baer (E. S. R., 14, p. 1012).

Some general conclusions regarding causes operative in Cheddar cheese ripening are stated as follows: "The earlier views as to the action of bacteria referred the main part of the work of digestion to the activity of liquefying bacteria. These organisms are capable of producing proteolytic enzyms, which digest the casein of milk with the formation of decomposition products, ranging from albumoses to the more ultimate product, ammonia. Numerous observations show that this type of bacteria occurs only sparingly in ripening Cheddar cheese, and it is difficult to believe that the exceedingly small quantities of digestive enzyms which would be produced can exert any considerable influence in the ripening process.

"As a normal cheese ripens, ammonia is always found, and the origin of this substance can not be attributed to either galactase or pepsin. Hence it seems probable that the activity of living organisms must be invoked to explain the origin of this product, but with the data at hand we are unable to state definitely what types of organisms are concerned.

"From our present knowledge the factors above mentioned are the chief agents which are operative in the ripening changes that occur in cheese. The initial changes are inaugurated by the lactic-acid bacteria which produce acid that unites with the paracasein forming a compound, paracasein monolactate, soluble in dilute salt solutions. This acid also supplies, even when combined with casein, the optimum conditions for the peptic digestion produced by rennet.

"The activity of galactase is undoubtedly operative from the beginning and continuous throughout the life of the cheese. The same is true of the pepsin in the rennet extract, which under certain conditions is probably the main factor in breaking down the casein of the cheese. It is exceedingly difficult, however, to assign to each of these agents the exact amount of proteolytic activity which it performs. Undoubtedly, the effect of environmental conditions (variation in acidity, temperature, etc.) determine somewhat the relative value of each.

"From our present knowledge of the processes which occur in the breaking down of the casein, we may consider that it has been definitely proven that the real digestive changes are almost, if not wholly, attributable to the action of proteolytic enzyms, and that bacteria play an insignificant rôle in this process, except so far as they prepare the way, by virtue of the acid which they form, for the subsequent changes which take place in the casein."

Cold curing of cheese (*Wisconsin Sta. Rpt. 1903, pp. 206–216, fig. 1*).—This is a summary of the following articles previously published by the station: Influence of Temperature on Ripening of Cheese, by S. M. Babcock and H. L. Russell (E. S. R., 10, p. 787); Influence of Cold Curing on Quality of Cheese, by S. M. Babcock, H. L. Russell, A. Vivian, and U. S. Baer (E. S. R., 13, p. 988); Influence of Cold Curing on Quality of Cheddar Cheese, by S. M. Babcock, H. L. Russell, A. Vivian, and U. S. Baer (E. S. R., 14, p. 1011); Curing of Cheddar Cheese with Reference to Cold Curing, by S. M. Babcock and H. L. Russell (E. S. R., 14, p. 490); The Cold Curing of Cheese. Report of experiments published as Bulletin 49, Bureau of Animal Industry, U. S. Department of Agriculture, in cooperation with New York [State] Agricultural Experiment Station, by S. M. Babcock, H. L. Russell, and U. S. Baer; Shrinkage of Cold Cured Cheese, by S. M. Babcock, H. L. Russell, and U. S. Baer (E. S. R., 15, p. 509); Conditions Affecting Development of White Specks in Cold Cured Cheese, by S. M. Babcock, H. L. Russell, A. Vivian, and U. S. Baer (E. S. R., 14, p. 1012), and Influence of Temperature Approximating 60° F. on Development of Flavor in Cold Cured Cheese, by S. M. Babcock, H. L. Russell, A. Vivian, and U. S. Baer (E. S. R., 14, p. 1012).

Experiments in paraffining cheese (*Wisconsin Sta. Rpt. 1903, pp. 217–219, fig. 1*).—This is a summary of the following articles previously published by the station: Coating Cheese with Paraffin, by J. W. Decker (E. S. R., 12, p. 91), and Experiments on Paraffining Cheese (see bulletin on Shrinkage of Cold Cured Cheese), by S. M. Babcock, H. L. Russell, and U. S. Baer (E. S. R., 15, p. 509).

Canning cheese, E. F. Pernot (*Oregon Sta. Bul. 78, pp. 8*).—This is a report on experimental work in canning cheese. The fresh milk as received at the dairy was inoculated with pure cultures and later treated according to the usual Cheddar process. Tin cans of various sizes were thoroughly cleansed and coated on the inside with paraffin.

In the earlier experiments the curd was placed in the cans and subjected to pressure. The best results were obtained by milling and canning one-half hour after salting. Less than the usual amount of salt was required. In the later experiments the curd was pressed in hoops, in the regular manner, and afterwards placed in cans of the same size. In all cases the cans were sealed hermetically immediately after being filled. Lots of from 6 to 15 cans were filled at a time and opened at regular intervals for examination.

"The first can was opened 6 weeks after being filled, and the cheese, for its age, was well ripened, of an excellent flavor and odor, the texture was friable, delicate, and quite superior to that of any other cheese. Several cans were opened at each of the various times, and a gradual increase of the delicate flavor was noticeable, but even in a can 1 year old it did not become strong and rank. There seemed to be a limit reached in the ripening, after which it remained unchanged. Very naturally there was no rind, no mold, and no loss in weight through evaporation; a pound of curd produced a pound of cheese."

The cans were placed in an ordinary room where the temperature rose in two instances to 80 and 100° F. The higher temperatures ruined all the cheeses that were in the different stages of curing. "After 3 months' curing change of temperature seemed to have no bad effect, but by far the most satisfactory results were obtained from cheese which was cured at a constant temperature of 60° F."

In order to test the shipping qualities of canned cheese, 1-lb. cans were sent by mail to China and return, and by express to England and return, and also to various points in the United States. It is reported that the cheese was uninjured by the shipping. It is stated, however, that cheese must be reasonably well cured before being subjected to the extreme changes of temperature incident to shipping long distances.

A study was also made of several pure cultures used to inoculate fresh milk which was subsequently made into cheese. A marked difference was observed in the flavor produced by different cultures. Four cultures were secured which gave good results. Bacteriological examinations made at the time of canning and when the cans were opened showed a material decrease in the number of bacteria.

The work, which has covered a period of nearly 2 years, is believed to have demonstrated the possibility and practicability of controlling the flavor of cheese by the use of pure cultures. Several lots of cheese made without previously inoculating the milk turned out very well.

The cheese industry in Franche-Comté, L. Macoir (*Bul. Agr. [Brussels], 20 (1904), No. 3, pp. 377-441, figs. 10*).—The methods employed in the manufacture of Camembert, Brie, Gruyère, Port-salut, and Septmoncel cheese are described in considerable detail, and an account is given of dairy instruction, dairy societies, milk control, etc., in this province of France. The author believes that the different kinds of cheese mentioned can be manufactured with equally good results in Belgium.

Annual report of the experiment station for cheese making at Lodi, 1903 (*Ann. R. Staz. Sper. Caseif. Lodi, 1903, pp. 76, fig. 1*).—This contains the usual review of the work of the station during the year, an account of the international dairy congress at Belgium, a discussion of the composition and nutritive value of whey, experiments in the manufacture of cheese from pasteurized milk, notes on a case of gassy cheese and on a milk filter, and the results of experiments on the use of pure cultures of lactic-acid bacteria in the ripening of cream.

Twenty-seventh annual report of the Iowa State Dairy Convention, 1903 (*Ann. Rpt. Iowa State Dairy Conv., 27 (1903), pt. 5, pp. 334*).—Addresses on the selection and feeding of cows, construction and use of silos, food value of feeding stuffs, butter making, cream ripening, handling and care of milk and cream, and other topics are included in the report.

Missouri State Dairy Association (*Ann. Rpt. Missouri State Bd. Agr., 36 (1903), pp. 90-139, pl. 1, figs. 3*).—This is a summary of the addresses delivered before the annual meeting of the association held in December, 1903.

Report of the thirty-fourth annual meeting of the Vermont Dairymen's Association, 1904 (*Rpt. Vermont Dairymen's Assoc., 34 (1904), pp. 156*).—This report contains rules for dairymen, as formulated by the association, and the addresses presented at the annual meeting, included Good Cheese and How to Make It, by J. W. Decker; The Vermont Dairy School, by J. L. Hills; and Dairy and Food Legislation, by H. C. Adams. Other matters of interest are also included in the report.

Officials, associations, and educational institutions connected with the dairy interests of the United States for the year 1904 (*U. S. Dept. Agr., Bureau of Animal Industry Circ. 44, pp. 12*).

VETERINARY SCIENCE AND PRACTICE.

Toxins and antitoxins, C. Oppenheimer (*Toxine und Antitoxine. Jena: Gustav Fischer, 1904, pp. 228*).—The purpose of this volume is to present a systematic account of all toxins of whatever nature and origin. Each toxin and its antitoxin is described in considerable detail. The subject-matter is classified according to its nature and includes a general discussion of toxins, the relation of toxins to antitoxins, true toxins, endotoxins and other bacterial poisons, plant toxins, and animal toxins.

Collected works relating to the problem of immunity, P. EHRLICH (*Gesammelte Arbeiten zur Immunitätsforschung. Berlin: August Hirschwald, 1904, pp. XII+776, figs. 12*).—In this book the editor has brought together the majority of the articles on immunity published by himself and associates during the last few years. The volume contains 38 articles dealing with various phases of immunity and serving to develop and elucidate the author's theory of immunity. The majority of the articles are based on experiments undertaken for the purpose of testing the value and applicability of the author's theories.

Report of the principal veterinary surgeon for the year 1903, S. B. WOOLLATT (*Natal. Agr. Jour. and Min. Rec., 7 (1904), No. 5, pp. 467–474*).—Notes are given on rinderpest, lung sickness, glanders, sheep scab, African coast fever, plant poisoning, etc. It has thus far proved impossible to exterminate rinderpest in Zululand. This fact is accounted for by the absence of fences and difficulties of inspection. Glanders is spread to considerable extent through the agency of condemned military horses.

Dipping and strict quarantine is recommended for the control of African coast fever. The Natal government recently passed an act relating to the prevention of this disease by quarantine.

Report of the third meeting of the official veterinarians of Prussia, December 12, 1903 (*Deut. Tierärztl. Wchnschr., 12 (1904), Nos. 4, pp. 29–34; 5, pp. 42–44*).—During the sessions of this meeting the members discussed the standing of the veterinary profession, the work of the veterinary service in executing the meat inspection laws, certain desirable modifications of the German law relating to animal plagues, and the inoculation method for preventing Texas fever. A detailed account was presented of the life history of cattle ticks and of the developmental stages of the blood parasite of Texas fever.

Reports of the colonial veterinary surgeon and the assistant veterinary surgeons for the year 1903, D. HUTCHEON (*Cape Town: Govt. Printers, 1904, pp. 88, pl. 1*).—This report contains an account of the work done during 1903 by the chief veterinary officer and his staff of assistants. Investigations were made with regard to the nature, symptoms, and treatment of heartwater, malarial catarrhal fever, rinderpest, redwater, African coast fever, glanders, tuberculosis, hog cholera, etc.

Brief reports are given by the various assistant veterinarians regarding the general health of animals in their districts. A method of preventive inoculation against heartwater is being perfected. Serum inoculation was successfully used in the control of rinderpest. Redwater is said to be extending gradually southward along the east coast.

A summary is given of the discussions had at an intercolonial veterinary conference. Resolutions were adopted regarding cooperation of the government veterinary officers in South African English colonies in the control of rinderpest, African coast fever, lung sickness, glanders, epizootic lymphangitis, scab, etc.

Handbook of meat inspection, R. OSTERTAG, trans. by E. V. WILCOX (*New York: W. R. Jenkins, 1904, pp. XXXV+886, pl. 1, figs. 260*).—This is a translation from the fourth German edition of Ostertag's well-known volume on meat inspection. The subjects covered include history and present status of meat inspection, laws, butchering, art of inspection before and after slaughter, normal appearance and differentiation of the meat of different animals, abnormal physiological conditions, general pathology, organic diseases, anomalies of the blood, intoxications, animal parasites, infectious diseases, emergency slaughter, post-mortem alterations in meat, adulteration of sausages, inflation of meat, preservation and sterilization of meat. J. R. Mohler prepared the introduction, which deals chiefly with the history and present status of meat inspection in the United States.

The new meat inspection, SEIGEL (*Deut. Tierärztl. Wchnschr., 12 (1904), No. 2, pp. 10–12*).—The author reviews certain cases in which infected or otherwise harm-

ful meat was admitted for use in the manufacture of sausages. Stricter supervision of traffic in such meat, and more severe punishment for offenders is urged by the author.

Cysticerci in Prag hams, C. DEIMLER (*Deut. Tierärztl. Wchnschr., 12 (1904), No. 9, pp. 81, 82*).—The author recommends thorough inspection of these hams in order to avoid, so far as possible, the passing of infested ones. These hams were found to be so badly infested that 1 or 2 cysticerci could be seen in every section. *Cysticercus cellulosæ* is considered to be still of very common occurrence in Austria.

Cysticerci, ZSCHOCKE (*Deut. Tierärztl. Wchnschr., 12 (1904), No 5, pp. 41, 42*).—It is argued that the destruction or proper treatment of measly beef may be brought about to a greater extent than at present by calling more attention to the connection between such meat and *Tænia saginata* in man.

Clinical notes, J. MAREK (*Ztschr. Thiermed., 8 (1904), No. 3-4, pp. 282-288*).—Notes are given on the symptoms, etiology, and treatment of influenza, petechial fever, hemoglobinemia, and vertebral fracture in the horse, and sarcoptic scabies in hogs. Certain cases of hemoglobinemia in horses were observed to be of a paralytic nature. In such cases the patellar reflex was wanting. No evidence was obtained that the disease was of parasitic origin.

An outbreak of sarcoptic mange in hogs is reported. The disease yielded to treatment with tar liniment and creolin. The disease was also transmitted to calves merely by close association.

Clinical instructions in veterinary medicine, MALKMUS (*Deut. Tierärztl. Wchnschr., 12 (1904), No. 6, pp. 49-53*).—Certain defects in the present system of veterinary instruction are pointed out. In order that this training may be more effective it is urged that more genuine enthusiasm be developed among students, that anatomy and physiology be taught by means of demonstrations on living animials, and that considerable knowedge of natural sciences be required before admission to advanced veterinary work.

Progress in the warfare against proprietary medicines, J. SCHMIDT (*Deut. Tierärztl. Wchnschr., 12 (1904), No. 9, pp. 82, 83*).—The Saxon Government decreed, December 21, 1903, that prosecution be undertaken against the sale of proprietary remedies or feeds which do not show a chemical composition corresponding to the claims made for them. In case of doubt concerning the nature of these preparations appeal is to be had to some agricultural experiment station for an expert opinion.

Therapeutic investigations in veterinary science during 1901 and 1902, E. BASS (*Deut. Tierärztl. Wchnschr., 12 (1904), No. 3, pp. 20-22*).—A brief review is given of the most important publications of 1901 and 1902 relating to mammitis, abscess, edema of the udder, and metritis.

Iodipin in veterinary medicine, MITTELDORF (*Berlin. Tierärztl. Wchnschr., 1904, No. 7, pp. 113-116*).—A critical review is presented of the literature on iodipin and related compounds. The physical and chemical characteristics of iodipin are described. This drug was used in the treatment of 16 cases of actinomycosis in cattle.

Lingual actinomycosis was completely cured, and considerable improvement was noted in cases of actinomycosis of the lymphatic glands. The iodipin was injected, usually in a 25 per cent solution, directly into the affected tissue. Good results were also obtained with the drug in the treatment of contagious coryza, angina of the pharynx, hepatic cirrhosis, and bronchial asthma.

Tallianin, C. ANGERSTEIN (*Berlin. Tierärztl. Wchnschr., 1904, No. 2, pp. 26, 27*).—Favorable results were obtained from intravenous injections of this drug in cases of laminitis, enteritis, contagious coryza, lymphangitis, parturient paresis, catarrhal bronchitis, etc. Tallianin appeared to exercise no injurious effects on horses, cattle, or dogs. In the treatment of milk fever improvement in the physical condition was

observable within 15 minutes and affected animals were able to stand within one hour.

The action of tallianin, GEORGES (*Berlin. Tierärztl. Wchnschr., 1904, No. 2, pp. 25, 26*).—This remedy is recommended for use in intravenous injections in doses of 1 to 20 cc. Excellent results were obtained with it in the treatment of 3 cases of pneumonia in horses. In severe cases the injection may be repeated at short intervals. The drug is considered harmless and as counteracting the action of the toxins of tetanus, dog distemper, etc.

Plaster of Paris bandages in veterinary practice, A. ZEHL (*Berlin. Tierärztl. Wchnschr., 1904, No. 4, pp. 57–59*).—The use of such bandages is recommended in cases of bone fractures or dislocations in horses, cattle, and other animals. In many cases the method is not as applicable as in human surgery but the results are usually satisfactory except where the conformation of the affected parts is unfavorable. Detailed clinical notes are presented on a number of cases in horses and cattle in which the author made use of plaster of Paris bandages.

Disinfecting power of coal-tar dips, L. L. LEWIS (*Oklahoma Sta. Bul. 62, pp. 16*).—The author compared the disinfectant power of zenoleum, cremoline, Lincoln dip, Carsul, chloro-naptholeum, carbolic acid, kerosene emulsion, etc. Some of the samples were fresh, others had been kept in the laboratory for periods ranging from 6 months to 2 years. No chemical analyses of the dips were made.

Several methods were tried in testing the dips, but the one finally adopted consisted in adding 5 cc. of a culture of the organism to be tested to 94 cc. of water and thoroughly mixing the whole. From this mixture cultures were made to serve as checks. After the check cultures were thus prepared 1 cc. of the disinfectant to be tested was added to the mixture of bacterial organisms and water. Cultures were then made from this mixture after the lapse of various periods.

The organisms used in these experiments were swine-plague bacillus, hog-cholera bacillus, anthrax bacillus, coli bacillus, etc. The details of the experiments are presented in a tabular form. It was found that in the laboratory a 1 per cent solution of commercial disinfectants was reasonably effective while under field conditions a 2 per cent solution was required. These proprietary dips compared favorably with carbolic acid and creolin.

These materials will be tested later to determine their action on external animal parasites. Attention is called to the necessity of making a thorough application of disinfectants in outbreaks of infectious diseases among domestic animals.

Recent developments in disinfection and sterilization, KAUSCH (*Centbl. Bakt. u. Par., 1. Abt., Ref., 34 (1904), No. 24–25, pp. 737–769, figs. 31*).—An elaborate review is presented of the details of construction in various apparatus used in disinfection and destruction of organisms pathogenic to animals and man. Some of the more interesting forms of apparatus used in the production of formaldehyde gas under pressure and other conditions are described. The author also considers disinfection by means of cresol, cobalt soap, manganese soap, and other antiseptics.

Formaldehyde apparatus, KAUSCH (*Centbl. Bakt. u. Par., 1. Abt., Ref., 34 (1904), No. 22–23, pp. 673–703, figs. 36*).—This apparatus is classified into groups according as the formaldehyde is produced from methyl alcohol, its polymeric modifications or by volatilization of solutions.

An apparatus for intravenous injection of large quantities of infectious cultures, A. CARINI (*Centbl. Bakt. u. Par., 1. Abt., Orig., 36 (1904), No. 2, pp. 318, 319, fig. 1*).—A convenient form of apparatus for this purpose is described in detail and illustrated. The apparatus can be used without danger of accident.

The infectiousness of the milk of tuberculous cows, LYDIA RABINOWITSCH (*Ztschr. Thiermed., 8 (1904), No. 3–4, pp. 203–219*).—The author discusses in a critical manner the results obtained by various investigators, including herself, in the study of tuberculous milk. While the results have varied in certain respects, they have

been remarkably uniform in indicating that tubercle bacilli may be and often are present in the milk of cows which are mere reactors and which, on post-mortem examination, show no recognizable tuberculous lesion.

Considerable space is devoted to a review of the work done by this Department. The author comes to the conclusion that tubercle bacilli are to be found in the milk of merely reacting cows quite commonly and much more frequently than has usually been assumed. Attention is therefore called to the great importance of preventing the spread of tuberculosis through the agency of the milk of tuberculous cows.

Investigations on bovine tuberculosis (*Wisconsin Sta. Rpt. 1903, pp. 250–255, fig. 1*).—A brief review of the results obtained in the following investigations previously published by the Wisconsin Station:

Tuberculosis and the Tuberculin Test (E. S. R., 6, p. 333); Efficiency of Tuberculin as a Diagnostic Agent in Tuberculosis (E. S. R., 8, p. 332); Infectiousness of Milk from Tuberculous Cows (E. S. R., 8, p. 334); Relation of Separator Slime to Tuberculosis in Hogs (E. S. R., 8, p. 334); Tuberculin Inoculations for 1896 (E. S. R., 9, p. 594); Restricting Tuberculosis by Isolation (E. S. R., 9, p. 591); History of a Tuberculous Herd of Cows, by H. L. Russell (E. S. R., 11, p. 986); Effect of Different Influences on Normal Temperatures of Cattle (E. S. R., 12, p. 92), by H. L. Russell and V. H. Bassett; Examination of Milk for Tubercle Bacilli (E. S. R., 12, p. 90), by V. H. Bassett; Bovine Tuberculosis in Wisconsin (E. S. R., 13, p. 284), by H. L. Russell and E. G. Hastings; Thermal Death Point of Tubercle Bacilli under Commercial Conditions (E. S. R., 13, p. 83).

The tuberculin reaction, FEISTMANTEL (*Centbl. Bakt. u. Par., 1. Abt., Orig., 36 (1904), No. 2, pp. 282–290*).—Some investigators have argued that the tuberculin reaction can not be considered as specific since tuberculous animals react to other substances than tuberculin and also since tuberculin may cause a reaction in diseases other than tuberculosis. Tuberculins from various sources were compared with the toxins of other closely related species of bacteria.

In order to declare positively for a reaction in any case the author required the fulfillment of the following conditions: Elevation of temperature, 1.2°; typical tuberculin curve; and the production of a temperature above any observed before injection or during the first day after injection. The final results will be published in a forthcoming article by the author.

Antifebrin used in masking the effects of tuberculin, A. GRÉGOIRE and J. HENDRICK (*Bul. Agr. [Brussels], 20 (1904), No. 3, pp. 445, 446*).—The authors describe in considerable detail a technical method for detecting this fraud by an examination of the urine. The drug may be demonstrated by means of the usual tests for acetanilid. It was found that paramidophenol could be detected in a solution of 1:10,000,000. The same test proved serviceable in demonstrating salicylic acid, which is also used occasionally in masking a tuberculin reaction.

Tuberculosis in hogs, L. L. LEWIS (*Oklahoma Sta. Bul. 63, pp. 8*).—The milk of tuberculous cows was fed to pigs in considerable quantities for a period of 2 months. The experiment showed that such milk contained tubercle bacilli and was pathogenic for hogs, some of which died of generalized tuberculosis.

The physical symptoms even in serious cases of tuberculosis in hogs were not very marked. The infected hogs were tested with tuberculin for the purpose of learning the value of this reagent in diagnosing tuberculosis in hogs. It was found that in hogs which were not used to being handled, the mere taking of the temperature caused an elevation of 1 to 2 degrees. In general, however, the results obtained from the tuberculin test were thoroughly reliable.

Anthrax in Wisconsin (*Wisconsin Sta. Rpt. 1903, pp. 256–258*).—This is a summary of the following articles: Outbreak of Anthrax Traceable to Tannery Refuse, by H. L. Russell, and Experiments on Treatment of Anthrax Hides with Formaldehyde Solutions, by E. G. Hastings (E. S. R., 13, p. 91).

Artificial immunity of rabbits toward anthrax, O. BAIL (*Centbl. Bakt. u. Par., 1. Abt., Orig., 36 (1904), No. 2, pp. 266–272*).—The experiment carried out by the author indicates that in rabbits the leucocytes play a more important rôle than the serum in the production of immunity. There appeared to be no constant relation between the precipitating and protecting power of rabbit blood with regard to anthrax. The author describes his bacteriological methods and gives notes on further experiments in which the serum of chickens and sheep was used in artificially immunizing rabbits to anthrax.

The occurrence of anthrax in the horse, FRANCKE (*Fortschr. Vet. Hyg., 2 (1904), No. 3, pp. 81, 82*).—Notes on anthrax as observed in the horse. Details are given on the symptoms and pathological anatomy of equine anthrax contracted from an affected cow. Infection apparently took place through a skin wound in the neck region. No alterations could be observed in the intestines.

Generalized actinomycosis, A. ASSMANN (*Deut. Tierärztl. Wchnschr., 12 (1904), No. 7, pp. 63, 64*).—Contrary to the generally accepted opinion, the author maintains on the basis of extensive statistics that generalized actinomycosis is of comparatively frequent occurrence. Detailed notes are given on the clinical history and post-mortem appearance of 11 such cases in cattle and hogs. From these notes it appears that a great variety of parts and organs may be simultaneously affected by actinomycotic lesions.

Milk fever in cows which have not calved and the etiology of milk fever, G. MEIER (*Berlin. Tierärztl. Wchnschr., 1904, No. 6, pp. 89–92*).—An elaborate account is presented of the nature of milk fever with critical references to the literature of the subject.

Detailed clinical notes are given on 5 cases of the disease in cows which had calved from 4 to 8 months previously. The author states that many other such cases have come under his observation. In such cases there is apparently no connection between calving and the disease. The author believes that previously announced hypotheses concerning the nature of milk fever must be abandoned. The idea that the disease is an intoxication is combated and discarded.

In the author's opinion the chief cause of milk fever is excessive rations of concentrated feeding stuffs. In localities in which the disease has increased most rapidly, heavy feeding with grains (up to 18 lbs. per day) has been indulged in for the purpose of increasing the milk flow. This excessive feeding may cause an unusual flow of blood to the udder. The author defines milk fever as a cerebral anemia caused by hyperemia of the udder and digestive apparatus.

The beneficial results obtained by pumping air, water, or other fluids into the udder are explained as due to the fact that thereby the excess quantity of blood is forced out of the udder. The name cerebral anemia is suggested to replace milk fever.

Infusion of air into the udder in cases of milk fever, E. WISSMANN (*Berlin. Tierärztl. Wchnschr., 1904, No. 9, pp. 153, 154*).—The author adopted this method in the treatment of 15 cases of milk fever, with complete recovery in 14 cases. Recovery took place in periods ranging from 20 minutes to 20 hours. The most important and most interesting points in the clinical history of these cases are presented in a tabular form. The author believes that mammitis need never develop as a result of this operation if ordinary care is exercised in cleaning the instruments and filtering the air.

Lead poisoning in cows, DÖHRMANN (*Berlin. Tierärztl. Wchnschr., 1904, No. 5, pp. 69, 70*).—In most cases of lead poisoning in cows observed by the author constipation was present, but less often a pronounced diarrhea was observed. In treating the trouble good results were sometimes obtained by administering Glauber salts. Sulphuric acid, however, was most effective. Badly poisoned animals gradually

become much emaciated. It is better, therefore, to slaughter them at once than to undertake the tedious and uncertain process of treatment.

An outbreak of acute lead poisoning in cows, DAMMANN (*Deut. Tierärztl. Wchnschr., 12 (1904), No. 1, pp. 2, 3*).—In a herd of 30 cows 19 became poisoned with lead which was deposited on the surface of sugar beets, together with silt carried by a flood. As treatment each cow received Glauber salts in 250 gm. doses 3 times daily. Recovery took place in 15 of the 19 affected cows after a period of 1 to 3 days.

Manual separation of the retained after-birth in cows, P. GRUNTH (*Ztschr. Thiermed., 8 (1904), No. 3-4, pp. 220-232*).—The literature of the subject is discussed in connection with numerous bibliographical references. Notes are given on the results obtained from rendering manual assistance in the removal of the after-birth within 24 hours after calving. The author believes that this is a desirable practice in all cases.

Prevention of white scour in calves (*Bd. Agr. and Fisheries* [*London*], *Leaflet 101, pp. 2*).—In preventing this disease thorough disinfection of the premises is recommended, together with antiseptic treatment of the navel immediately after birth.

Milk treated with formalin, a new remedy for calf dysentery, M. KLIMMER (*Ztschr. Thiermed., 8 (1904), No. 3-4, pp. 289-291*).—Some evidence has been obtained in favor of the belief that cows which have been immunized against tuberculosis by the method of von Behring yield milk containing immune bodies and tending to increase the resisting power of calves and children toward tuberculosis.

Proceeding on this basis it seemed desirable to find a method of milk sterilization which would not destroy the immune bodies in the milk. Pasteurization has such effect. Resort was therefore had to the use of formalin. It was found that milk could be sterilized and preserved for long periods by adding formalin at the rate of 1:4,000. Milk containing that proportion of formalin had no bad effect on calves or children and was found to be very efficient in preventing and curing calf dysentery.

Preventive treatment for infectious dysentery of calves, A. TROST (*Ztschr. Thiermed., 8 (1904), No. 3-4, pp. 291-293*).—An outbreak of this disease is described in which finally all the calves on the estate died. Endovenous injections of 0.05 per cent collargol were tried on 14 calves. All calves which were treated within a few hours after birth remained healthy. A few of those which were not immediately injected developed the disease, but only 3 died.

Can the "Piroplasma bigeminum" find a habitat in the human subject? A. LINGARD (*Centbl. Bakt. u. Par., 1. Abt., Orig., 36 (1904), No. 2, pp. 214-216, pl. 1*).—Brief notes are given on the variations in form of the blood parasite of Texas fever under different conditions. The author discusses in some detail a case of a cattle attendant who developed a disease closely resembling Texas fever while associated with cattle affected with this disease. Blood parasites were found which could not be distinguished from those of Texas fever.

Preliminary report on the study of rinderpest of cattle and carabaos in the Philippine Islands, J. W. JOBLING (*Philippine Dept. Int., Bureau Govt. Lab.* [*Pub.*], *1903, No. 4, pp. 22, pl. 1*).—A general discussion of the symptoms, prevention, and treatment of rinderpest. In preventing the disease the best results are obtained by the serum method. The advantages of this method consist in the facts that no reaction is produced; no suppression of milk flow occurs; immunity is almost immediately developed, and no abortion occurs. The amount of serum required is 15 to 20 cc. according to the susceptibility of the animal.

It is argued that by applying preventive inoculation to all animals now in the Philippines and to all animals imported hereafter the disease can be eradicated in the islands. No treatment is satisfactory.

A report on hemorrhagic septicemia in animals in the Philippine Islands, P. G. WOOLLEY and J. W. JOBLING (*Philippine Dept. Int., Bureau Govt. Lab.* [*Pub.*],

1903, No. 9, pp. 21).—This disease first appeared in the Philippines in cattle imported from Shanghai in 1903.

Notes are given on the history of this outbreak and on the distribution of the disease throughout the world. The clinical symptoms and lesions in 13 cases in carabaos are described in detail. Acute and chronic cases were noted. Classified according to pathological lesions the disease presents two types, the pulmonary and the septicemic. The same organism was isolated from both types of cases. In laboratory experiments, this organism proved pathogenic for guinea pigs, rabbits, monkeys, dogs, and chickens. Thus far the authors have been unable to obtain any serum of value in treating or preventing the disease.

Some pulmonary lesions produced by the bacillus of hemorrhagic septicemia of carabaos, P. G. WOOLLEY (*Philippine Dept. Int., Bureau Govt. Lab.* [*Pub.*], *1903, No. 12, pp. 11*).—The different kinds of pathological lesions produced by this disease are described in detail. In one carabao the lesions were almost identical with those of pleuro-pneumonia. Smear cultures from the cardiac blood killed guinea pigs within 20 hours.

In another case there were small pericardial hemorrhages about the base of the heart. The organism isolated from this case was pathogenic for monkeys, small birds, guinea pigs, and rabbits. In a third case in a horse the lungs showed congestion, the air cells were distended, and the fibrous tissue was increased in amount. The author is unable to explain how the organism of hemorrhagic septicemia gained access to the lungs in these 3 cases.

Bronchitis due to barley chaff, BEHRENS (*Deut. Tierärztl. Wchnschr., 12 (1904), No. 7, pp. 62, 63*).—An outbreak of bronchitis in sheep led to the institution of experiments to determine whether dry cotton-seed meal could cause the disease. Negative results were obtained from these experiments with sheep. Further observations, however, showed conclusively that the inhalation of barley chaff may cause fatal bronchitis in cattle.

In one case due to this cause the lungs were found to be hepatized, especially in the anterior portions. An examination of microscopic preparations from the lungs and bronchi disclosed the fact that the tissue had been punctured and irritated by fragments of barley chaff.

Sheep scab in Tasmania (*Agr. Jour. Cape Good Hope, 24 (1904), No. 6, pp. 730–732*).—A brief statement of how the disease was exterminated in Tasmania within a period of 8 years. The dip used was made of lime and sulphur.

Necrosing mastitis, ZOBEL (*Deut. Tierärztl. Wchnschr., 12 (1904), No. 11, pp. 101, 102, fig. 1*).—The symptoms and pathological anatomy of this disease are described with especial reference to a case in a goat. This case was of 13 weeks' standing and a large abscess had formed and broken. The case was diagnosed as parenchymatous mastitis.

Horse sickness and its prevention, R. KOCH (*Agr. Jour. Cape Good Hope, 24 (1904), No. 6, pp. 663–675*).—The author found that in order to secure uniform results in the production of artificial immunity to horse sickness it is necessary to give careful attention to the preparation of the virus and serum. Both of these products can be preserved for a long period.

For the sake of economy it is desirable that the virus be just strong enough to cause an attack of the disease, and that the serum be capable of holding the disease within safe limits. When this method is further perfected the author hopes that the process of immunizing susceptible horses will not require more than 4 to 6 weeks. Detailed directions are given for the preparation of both virus and serum.

Horse sickness, R. KOCH (*Natal Agr. Jour. and Min. Rec., 7 (1904), No. 5, pp. 479–481*).—Immune horses were secured and inoculated with virulent blood in order to intensify the immunity. A maximum dose of 2,000 cc. was injected without bad

effects. After this process had been continued for several months the serum of treated animals was found to have considerable protective power.

Experiments on 5 horses demonstrated that serum from treated animals is capable of protecting susceptible animals from lethal doses of virulent blood. The serum has no striking curative properties. It is not hemolytic, and causes no hemoglobinuria. By means of combinations of virus and serum it was found possible to produce a mild form of horse sickness, which in turn conferred a lasting immunity from the disease. The author believes that a practical method of immunization has been found.

A preliminary report on trypanosomiasis of horses in the Philippine Islands, W. E. Musgrave and N. E. Williamson (*Philippine Dept. Int., Bureau Govt. Lab.* [*Pub.*], *1903, No. 3, pp. 26, pls. 2*).—The authors discuss the history of the epidemic in the Philippines, the mode of transmission, symptoms, diagnosis, and preventive measures. The position is taken that infection occurs through skin wounds produced by biting flies, fleas, lice, mosquitoes, etc. Apparently, infection can not take place through the healthy intestines. The authors' experiments confirm this belief.

The symptoms and lesions are described in considerable detail. In the Philippines the disease is invariably fatal to horses. Thus far the authors have not observed the disease in cattle or carabaos. In preventing the spread of this disease proper quarantine and sanitary measures should be adopted. It is urged that all animals affected with the disease be immediately destroyed and that the carcasses be burned or that flies and other biting insects be prevented from gaining access to the body.

Poisoning from harmful and adulterated feed stuffs, Hoehne (*Berlin. Tierärztl. Wchnschr., 1904, No. 4, pp. 59–61*).—Several hogs were fatally poisoned by eating rye meal. Post-mortem examination showed an inflammatory condition of the intestinal mucous membrane. Petechiæ were observed on the auricles of the heart. The cause of poisoning was not definitely determined. Similar cases were observed in other animals.

Certain cases were evidently due to adulteration of the milling products used as feed. Samples of rye studied by the author contained 8.25 per cent of corn-cockle seed. It was found that corn cockle exercised a poisonous action on hogs. The seed of the hairy vetch was also shown to be poisonous to hogs although the green forage was very palatable and quite harmless. The author recommends a stricter inspection of feeding stuffs and severe punishment for the sale of adulterated feed. It is believed that in certain localities the loss of swine from poisonous feeds is as great as from infectious diseases.

Results from fighting swine erysipelas in the Grand Duchy of Hessen, 1901–1903, Lorenz (*Ztschr. Thiermed., 8* (*1904*), *No. 3–4, pp. 261–281, dgm. 1*).—The results of preventive vaccination under government auspices in the control of this disease have proved to be very encouraging. Vaccinated animals have been protected against infection and swine erysipelas has not been spread by the extensive adoption of vaccination, as claimed by certain authors. The expense of vaccination is not great and is justified by the results. The extensive data upon which the author's discussion is based are presented in tabular form.

Swine plague and fowl cholera, Georges (*Berlin. Tierärztl. Wchnschr., 1904, No. 1, pp. 5, 6*).—Attention is called to the close relationship between these two diseases. A serious outbreak of swine plague occurred on an estate where the disease was previously unknown but where fowl cholera had prevailed extensively. The affected hogs had been allowed to run in the chicken yard.

A second outbreak of swine plague occurred under similar circumstances and with much more convincing evidence of the relationship between this disease and fowl cholera. Feed which had been contaminated by the diseased hogs was fed to geese

with the result that all the geese died of fowl cholera. It is recommended that hogs and domestic fowls be kept in separate yards.

Swine plague and fowl cholera, KLEINPAUL (*Berlin. Tierärztl. Wchnschr., 1904, No. 9, p. 150*).—In opposition to Georges, the author takes the position that the simultaneous occurrence of these diseases on the same estate furnishes no evidence of their relationship or identity. Attention is called to the fact that both swine plague and fowl cholera are of almost universal distribution and must sometimes occur simultaneously in one locality.

Fowl cholera, A. R. WARD (*California Sta. Bul. 156, pp. 20*).—Fowl cholera occurred in a serious outbreak in California in 1903, and this outbreak gave an opportunity to the author to study the disease. It appeared to be very rapidly fatal, a large percentage of infected fowls dying within 3 days after exposure. It was found to be an easy matter to infect healthy fowls by feeding them on the entrails and flesh of birds dead of the disease. Infection may also be spread to some extent by means of the fluid which drips from the beaks of infected fowls.

Experiments were carried on in disinfecting poultry houses by means of crude carbolic acid and crude sulphuric acid mixed in equal proportions at the rate of ½ gal. of each to 20 gal. of water. This mixture was effective, but was objectionable on account of ruining clothing and rubber hose and producing sores on the skin of the workmen. Crude carbolic acid used alone was objectionable on account of the difficulty in keeping it mixed with water. Crude carbolic acid and phenolene used in equal parts, mixed at the rate of ½ gal. each to 20 gal. of water, proved very satisfactory.

In order to supplement the general process of disinfection by further preventive measures, the author tested the effect of adding corrosive sublimate to the drinking water at the rate of 1 part to 2,000. No injurious effects were produced upon the birds. The result of these two disinfectant measures was rapidly to reduce the death rate and ultimately to eradicate the disease. In controlling fowl cholera the author recommends, as one of the most important remedies, the burning or burying of dead fowls, or preferably their destruction, as soon as the slightest symptoms are shown.

The symptoms of fowl cholera are punctiform hemorrhages upon the heart and similar whitish spots on the liver. The first-named lesion is present in all cases, and the second in more than half of the cases. The excreta are yellowish, and the birds refuse to eat but appear to be thirsty. A marked drowsiness is observed together with a rising of temperature. Turkeys seem to be affected in the same manner as common fowls. The behavior of the fowl-cholera bacillus upon various nutrient media is described, and notes are given on its reaction to heat and disinfectants. The organism appears to be pathogenic for various fowls and pigeons, as well as for guinea pigs.

Phosphorus poisoning in fowls, SCHMUTZER (*Berlin. Tierärztl. Wchnschr., 1904, No. 5, pp. 70, 71*).—Phosphorus poisoned fowls showed pronounced opisthotonus just before death. The odor of phosphorus was present in the stomach contents. The phenomenon of phosphorescence was observed when the stomach contents were rubbed between the fingers in a dark room. Ecchymoses on the surface of the heart constitute an almost constant pathological alteration in cases of phosphorus poisoning.

A new fatal eye disease of pheasants (*Berlin. Tierärztl. Wchnschr., 1904, No 2, pp. 28, 29*).—During the progress of the disease described in this paper the cornea of affected pheasants became cloudy. Later a purulent process developed, resulting in an abscess of considerable size and involving the supraorbital space. Death took place in all cases after about 10 days. The application of antiseptic washes seemed to hasten the fatal outcome rather than check the disease.

An interesting tapeworm of pigeons, K. WOLFFHÜGEL (*Berlin. Tierärztl. Wchnschr., 1904, No. 3, pp. 45–48, figs. 4*).—Detailed notes are given on the anatomi-

cal peculiarities of *Bertia delafondi* as found in the small intestines of the common pigeon. The literature of the subject is briefly reviewed.

A bacillus found in eggs, L. PALMANS (*Bul. Agr. [Brussels], 20 (1904), No. 3, pp. 447–452*).—A bacillus was isolated from hens' eggs and was found to be pathogenic for guinea pigs but not for pigeons, rabbits, or chickens when inoculated in small doses. Morphologically the organism could hardly be distinguished from the anthrax bacillus, which it also closely resembled in its behavior on various culture media. The author suggests that this organism may be a parent form of *Bacillus anthracis* and *B. subtilis*.

The formation of toxins by rabies virus, O. HELLER and E. BERTARELLI (*Centbl. Bakt. u. Par., 1. Abt., Orig., 36 (1904), No. 2, pp. 216–222*).—The literature of this subject is critically discussed in connection with a short bibliography. The purpose of the authors' experiments was to determine whether rabies toxins are combined with certain bodies or are free in the fluids of the tissues. The brain and spinal cord of rabid rabbits were tested with this object in view.

It was found that the brain substance of rabid animals is toxic, while that of normal animals is toxic to a smaller extent. The symptoms produced by rabies toxin are not uniform or constant. Experimental animals gradually acquired a certain resisting power toward repeated injections of brain substance. No immunity is produced, however, by inoculation of noninfectious material.

Chorea in dogs, E. JOEST (*Ztschr. Thiermed., 8 (1904), No. 3–4, pp. 179–201*).—The literature of this subject is critically reviewed, together with detailed notes on a case observed by the author. The symptoms in all cases appear to be quite similar, the most characteristic symptom being irregular muscle contractions. The disease runs a slow course, with ultimate recovery in most cases. Chorea is almost without exception a sequela of distemper. Human and canine chorea have much in common. Both occur after infectious diseases and are accompanied by almost identical lesions in the central nervous system.

Salipyrin poisoning in dogs infested with Ascaridæ, HAASE (*Berlin. Tierärztl. Wchnschr., 1904, No. 5, p. 70*).—The administration of salipyrin in small doses to dogs was found to produce epileptiform spasms and acute gastritis, followed by death. The dogs were infested with *Ascaris mystax*, which had already brought about a serious intestinal catarrh.

The extirpation of wild carnivora, J. M. ORPEN (*Agr. Jour. Cape Good Hope, 24 (1904), No. 6, pp. 689–694*).—Attention is called to the danger from the spread of rabies in southern Africa. In order to prevent this the author recommends the destruction of all carnivorous animals which may carry the disease. Various methods of trapping, poisoning, or otherwise killing carnivora, including rats, are described.

AGRICULTURAL ENGINEERING.

Irrigation in humid climates (*Wisconsin Sta. Rpt. 1903, pp. 318–332*).—A summary of investigations during the 10 years ending with 1903. The following articles are included:

Amount of water necessary for the production of a pound of dry matter, by F. H. King (pp. 318–322).—The Amount of Water Required to Produce a Pound of Dry Matter in Barley, Oats, Corn, Clover, and Peas in Wisconsin (E. S. R., 5, p. 484); The Amount of Water Required to Produce a Pound of Dry Matter in Wisconsin (E. S. R., 7, p. 567); The Number of Inches of Water Required for a Ton of Dry Matter in Wisconsin (E. S. R., 8, p. 293); The Importance of Right Amount and the Right Distribution of Water on Crop Production (E. S. R., 10, p. 746).

Amount of water needed for maximum crops under field conditions (pp. 323–332).—The Influence of the Water Pumped on the Yield of Crops Grown on the Area, by F. H. King (E. S. R., 8, p. 295); Experiments in Irrigation, by F. H. King (E. S. R.,

8, p. 733; 9, p. 594); The Importance of the Right Amount and Right Distribution of Water on Crop Production, by F. H. King (E. S. R., 10, p. 746; 11, p. 537); The Influence of the Right Amount and Right Distribution of Water on Crop Production, by F. H. King (E. S. R., 12, p. 40; 13, pp. 34, 936); Relation of Crop Production to Amount of Water Available and Method of Cultivation, by A. R. Whitson (E. S. R., 14, p. 955).

The right way to irrigate, J. A. Widtsoe and W. W. McLaughlin (*Utah Sta. Bul. 86, pp. 53–101, pls. 8, figs. 23*).—This is a popular exposition of some of the results reported in Bulletin 80 of the Utah Station (E. S. R., 15, p. 655).

An irrigation system in the region of Hyères, J. Farcy (*Jour. Agr. Prat., n. ser., 7 (1904), No. 9, pp. 619–622, figs. 2*).—A system for irrigating about 75 acres from wells is described.

The railroads and the wagon roads (*U. S. Dept. Agr., Office of Public Road Inquiries Circ. 37, pp. 4*).—This paper was read by A. L. Craig, general passenger agent of the Oregon Railroad and Navigation Co., before the Oregon State Good Roads Association at its first annual convention, held in Portland, October 24, 1903.

List of National, State, and local road associations and kindred organizations in the United States (*U. S. Dept. Agr., Office of Public Road Inquiries Circ. 36, rev., pp. 14*).

Problems in farm mechanics, F. H. King (*Wisconsin Sta. Rpt. 1903, pp. 346–353*).—A summary of investigations during the 10 years ending with 1903. The following articles are included:

Silos (pp. 346–349).—The Construction of Silos (E. S. R., 3, p. 248), The Construction of Silos and the Making and Handling of Silage (E. S. R., 9, p. 393), Silage and the Construction of Modern Silos (E. S. R., 12, p. 495).

Country roads (pp. 349–352).—Principles of Construction and Maintenance of Country Roads (E. S. R., 11, p. 1095).

Feed grinding (pp. 352, 353).—Experiments in Grinding with Small Steel Feed Mills (E. S. R., 12, p. 492).

The history, construction, and critical examination of mowing machines, A. Nachtweh (*Landw. Jahrb., 32 (1903), No. 5–6, pp. 655–772, pls. 6, figs. 111*).—The history of the development of the mowing machine is reviewed, the general construction of such machines is discussed, and results of detailed examinations of a large number of makes are reported.

Electricity in agriculture, E. Guarini (*L'électricité agricole. Lausanne: Société Suisse d'Édition; Paris: Fischbacher [1904], pp. 162, ill.; rev. in Jour. Agr. Prat., n. ser., 7 (1904), No. 16, p. 525*).

MISCELLANEOUS.

Twenty-Seventh Annual Report of Connecticut State Station, 1903 (*Connecticut State Sta. Rpt. 1903, pp. XIV*).—These pages accompanying part 5 of the report of the station for the year ended October 31, 1903, contain an announcement concerning the work of the station; a brief report of the board of control on the work of the station during the year, and a financial statement for the year ended September 30, 1903.

Thirty-Seventh Annual Report of the Connecticut State Board of Agriculture, 1903 (*Connecticut State Bd. Agr. Rpt. 1903, pp. 325*).—Among the addresses delivered at the meeting of the board held in December, 1903, and published in this report, are the following: Agricultural Fairs Improvement, by H. B. Cowan; Dairying in France, by H. E. Alvord; Evolution of Farm Machinery and its Effect upon the Life and Business of the Farmer, by J. M. Hubbard; Farmers' Institutes, by J. Hamilton; Intensive Cultivation, by G. M. Clark; Potato Growing in Connecticut, by A. L. Clinton; Reminiscences of Thirty Years of Agricultural Science in Connecticut, by W. O. Atwater; The Corn Crop in Connecticut, by E. H. Jenkins;

The Commercial Side of Fruit Growing, by J. H. Hale; The Cow Feeder's Great Problem, by F. S. Cooley; The Decline in the Value of New England Land—How to Arrest and Improve it, by G. T. Powell; and The Education of the American Farmer, by K. L. Butterfield.

Annual Report of Idaho Station, 1903 (*Idaho Sta. Rpt. 1903, pp. 34*).—This contains the organization list of the station; a financial statement for the fiscal year ended June 30, 1903; and reports of the director and heads of departments on the different lines of station work during the year. The report of the meteorologist is noted elsewhere.

Sixteenth Annual Report of Louisiana Stations, 1903 (*Louisiana Stas. Rpt. 1903, pp. 24*).—This contains reports of the work of the Sugar Station at Audubon Park, the State Station at Baton Rouge, and the North Louisiana Station at Calhoun; notes of the geological and soils surveys being made in the State; the organization lists of the stations, and a financial statement for the fiscal year ended June 30, 1903.

Nineteenth Annual Report of Maine Station, 1903 (*Maine Sta. Rpt. 1903, pp. 219*).—This is made up of Bulletins 89–99 of the station on the following subjects: Experiments in orchard culture (E. S. R., 15, p. 39), fertilizer inspection (E. S. R., 15, p. 26), the chinch bug in Maine (E. S. R., 15, p. 56), feeding stuff inspection (E. S. R., 15, p. 287), poultry experiments in 1902 (E. S. R., 15, p. 394), fertilizer inspection (E. S. R., 15, p. 348), nitrate of soda and muriate of potash as top-dressing for grass land (E. S. R., 15, p. 355), dandelions (E. S. R., 15, p. 360), hawkweeds (E. S. R., 15, p. 372), ginseng (E. S. R., 15, p. 360), cankerworms (E. S. R., 15, p. 381), plant-house aleurodes (E. S. R., 15, p. 882), wheats and flours of Aroostook County (E. S. R., 15, p. 867), potato experiments in 1903 (E. S. R., 15, p. 972), notes on the Angora goat (E. S. R., 15, p. 996), the preservation of hen manure (E. S. R., 15, p. 958), and finances, meteorology, and index (E. S. R., 15, pp., 956, 1025).

Fifteenth Annual Report of New Hampshire Station, 1903 (*New Hampshire Sta. Bul. 104, pp. 83–98*).—This includes the organization list of the station, a financial statement for the fiscal year ended June 30, 1903, and brief reports of the vice-director and heads of departments. The report of the chemist contains analyses of a number of samples of cattle and poultry foods.

Sixteenth Annual Report of Rhode Island Station, 1903 (*Rhode Island Sta. Rpt. 1903, pp. 173–300 + VII*).—This contains the organization list of the station; a report of the director reviewing the different lines of station work during the year and calling attention to the needs of the station; departmental reports noted elsewhere; a financial statement for the fiscal year ended June 30, 1903, and lists of donations and exchanges.

Twentieth Annual Report of Wisconsin Station, 1903 (*Wisconsin Sta. Rpt. 1903, pp. 414*).—This contains the organization list of the station; a report of the director; a description of the new agricultural building and a history of the agricultural college and experiment station of the University of Wisconsin, by W. A. Henry; numerous articles summarizing the work of the experiment station during the last 10 years; lists of exchanges and acknowledgments, and a financial statement for the fiscal year ended June 30, 1903.

The Royal Agricultural Academy of Bonn [Poppelsdorf], P. Rolley (*Ann. Inst. Nat. Agron., 2. ser., 3 (1904), No. 1, pp. 75–128, figs. 8*).—This is an account of the history, equipment, and organization of this institution, with a detailed outline of the courses of instruction and statistics as regards attendance.

[Reports of the agricultural experiment stations in Austria] (*Ztschr. Landw. Versuchsw. Oesterr., 7 (1904), No. 4, pp. 265–364*).—This includes reports of the following experiment stations: Agricultural Experiment Station for Plant Culture, Brünn; Experiment Station of the Lower Austrian Agricultural, Horticultural, and Viticultural Schools, Feldsberg; Agricultural Chemical Experiment and Seed Control Station, Gratz; Agricultural Chemical Experiment Station of the Royal Imperial

Agricultural Society of Carnithia, Klagenfurt; Agricultural Chemical Experiment Station for Carniola, Laibach; Chemical Experiment Station, Lobositz; Agricultural Institute and Experiment Station, St. Michael-on-the-Etsch; Agricultural Physiological Experiment Station of the Bohemian Section of the Agricultural Council for the Kingdom of Bohemia, Prague; Experiment Station for the Sugar Industry, Prague; Agricultural Botanical Experiment Station of the Royal Bohemian Agricultural Academy at Tabor; Station for Plant Diseases and Plant Protection of the Royal Agricultural Academy of Tabor; Agricultural Chemical Experiment Station of the State Agricultural Academy, Tetschen-Liebwerd, and the Agricultural Botanical Experiment and Seed Control Station, Troppau.

Rise and decline of extensive agriculture in England, H. LEVY (*Entstehung und Rückgang des Landwirtschaftlichen Grossbetriebes in England. Berlin: Julius Springer, 1904, pp. VI-247*).—The origin and development of extensive agriculture in England from 1750 to 1880 are considered, and agricultural conditions as existing at present are discussed. The following subjects are given especial attention: Changes in conditions affecting agricultural production and markets; size of farms; economic causes of a new development in farm management; social and political factors in their relation to agriculture at the present time; economic advantages and disadvantages of farms of certain sizes; and agricultural societies.

Agriculture and animal husbandry in Norway, 1896-1900, A. N. KIÄR (*Norges Offic. Statistik, 4. ser., 1903, No. 72, pp. LIV+252*).—Statistical data are reported. The total area of arable land in Norway is given as 213,847 hectares, or 0.66 per cent of the total land surface. The farms numbered 159,255, the average size of each being 1.34 hectares (3.3 acres). Potatoes, oats, barley, and rye were the leading crops. The number of horses was 172,999, cattle 950,201, sheep 998,819, goats 214,594, swine 165,348, reindeer 108,784.

The average yield of milk per cow was 1,279, or for the more progressive farmers, 1,729 liters, the average price for new milk 10.78 öre (2.89 cts.) per liter, and for butter 1.64 kroner (44 cts.) per kilogram. The total number of creameries was 783, of which number 765 received a total of very nearly 170,000,000 kg. of milk. The number of cheese factories was 62, sixty of which used 14,000,000 kg. of milk.—F. W. WOLL.

Report of committee on indexing agricultural literature, A. C. TRUE ET AL. (*U. S. Dept. Agr., Office of Experiment Stations Circ. 54, pp. 2*).—This report has already been noted (E. S. R., 15, p. 324).

The relation of the natural sciences to agriculture in a four-year college course, A. C. TRUE ET AL. (*U. S. Dept. Agr., Office of Experiment Stations Circ. 55, pp. 15*).—This is a report of the committee on methods of teaching agriculture of the Association of American Agricultural Colleges and Experiment Stations, and has already been noted (E. S. R., 15, p. 325).

Constitution of the Association of American Agricultural Colleges and Experiment Stations, as amended at the seventeenth annual convention of the association, Washington, D. C., November 17-19, 1903 (*U. S. Dept. Agr., Office of Experiment Stations Circ. 56, pp. 4*).

Agricultural exports of the United States, 1851-1902, F. H. HITCHCOCK (*U. S. Dept. Agr., Division of Foreign Markets Bul. 34, pp. 100, dgm. 1*).—A statistical report showing the quantity, value, and average price of the various agricultural products exported by the United States during each fiscal year from 1851 to 1902, inclusive.

Foreign import tariffs on grain and grain products, 1903, F. H. HITCHCOCK (*U. S. Dept. Agr., Division of Foreign Markets Bul. 37, pp. 59*).

NOTES.

Alabama College.—G. H. C. Williams, a graduate of the Pennsylvania State College, has been appointed instructor in agriculture.

Alaska Station.—Fred E. Rader, who has been an assistant at the Sitka Station since the spring of 1900, assumed charge of the station at Rampart July 1. For want of means this station has never been equipped, although Isaac Jones was stationed there from August, 1900, to September, 1901. He cleared a patch of ground and successfully raised winter rye, barley, oats, and hardy vegetables. When he resigned in 1901 the funds did not admit of putting another man in his place, but now that the most necessary pioneer work has been done at the other stations, the Rampart Station will be equipped with implements. Land will be cleared, a house built, and a determined effort will be made to show what the agricultural capabilities are in that region. The station is located in latitude 65° 30′, and is probably the most northern agricultural experiment station in the world.

Arizona Station.—V. A. Clark, recently assistant in horticulture at the New York State Station, has been elected horticulturist to the Arizona Station, and will be located on the station farm at Phoenix.

Arkansas University and Station.—G. A. Cole, instructor in mathematics and bookkeeping in the college, has been elected to succeed C. L. Newman, agriculturist in the college and station, who has severed his connection with that institution.

California University and Station.—C. W. Woodworth has been promoted from assistant professor to associate professor of entomology. C. M. Haring has been appointed instructor in veterinary science and bacteriology. F. T. Bioletti, formerly of this station, and now of the Elsenburg School of Agriculture, Cape Colony, has been appointed assistant professor and viticulturist, vice E. H. Twight, resigned.

Colorado College.—According to press reports, the college has purchased what is known as the "Model Colorado Farm," adjacent to the college grounds, to be used for extending the work of the college and station. The farm comprises 80 acres of land, and the price paid is reported as $26,000.

Connecticut College and State Station.—Owing to the large number of applicants for admission to the Connecticut Agricultural College, a press bulletin has been issued by this institution announcing the discontinuance of the customary August entrance examinations at Hartford, New Haven, Danbury, and Norwich. Already more students than can be accommodated in the dormitories of the institution have qualified for entrance on the opening of the fall term, September 21. Alfred Akerman succeeded Walter Mulford as station forester on July 1.

Florida University and Station.—At a meeting of the board of trustees the latter part of June, the resignations of T. H. Taliaferro, president and director, H. A. Gossard, entomologist, H. K. Miller, chemist, and R. A. Lichtenthaeler, assistant chemist, were called for and accepted.

Hawaiian Sugar Planters' Station.—A division of entomology has recently been added to the experiment station and will occupy quarters adjoining the agricultural division. New offices, insectaries, and a large cane propagation house are being

erected. The staff of the new division includes the following: R. C. L. Perkins, superintendent; A. Koebele, consulting entomologist; G. W. Kirkaldy, F. W. Terry, and Otto Swezy, assistant entomologists.

Illinois University.—By request, the university is preparing an exhibit of the market classes of cattle, to be shown at the St. Louis Exposition, September 12–24, in connection with the exhibits of the colleges and experiment stations. It is not generally known that a complete exhibit of this kind requires some forty-eight animals, even when but one specimen of each recognized grade is shown. The stall of each animal will be fully labeled, giving class and grade to which the animal belongs and for what purpose that particular kind is used. This will without doubt be one of the most attractive exhibits at the exposition.

Iowa College and Station.—W. H. Olin, assistant in field crops, has resigned to accept the head of the department of agronomy at the Colorado College and Station. L. S. Klinck, a graduate of the Ontario Agricultural College, has been elected to succeed him. O. W. Wilcox has been elected to the position of assistant in soils. Dr. Wilcox is a graduate of the University of Texas and has taken a Ph. D. degree at the University of Chicago. J. W. Jones has been elected assistant in farm crops to succeed T. S. Hunt. J. B. Weems has resigned his position as station chemist. A successor has not yet been elected. Hugh G. Baker, who is at present connected with the Bureau of Forestry, has been elected assistant in the department of horticulture. Mr. Baker is a graduate of the Michigan Agricultural College and has recently completed the course in forestry at Yale. He will devote one-half of his time to forestry work of the college and one-half to work of the Bureau of Forestry. E. S. Gardner, of Denver, Colo., has been elected to the position of station photographer; W. J. Rutherford has been advanced to the position of associate professor of animal husbandry and professor in charge during Professor Kennedy's absence; and Carl W. Gay has been appointed temporary assistant during the latter's absence. Wayne Dinsmore, W. W. Smith, and J. A. Conover have also been elected assistants in the department of animal husbandry, and M. L. Merritt assistant in horticulture.

Contracts have been let for the erection of a new fireproof dairy building that will cost, when completed January 1, 1905, about $60,000; and a horticultural barn and storage room to cost about $6,000.

Michigan College and Station.—B. O. Longyear, the botanist of the station, has resigned to take up similar work with the Colorado Station. Professor Longyear had, before going, nearly completed a monograph on the fleshy fungi, part of which had been published as Bulletin 208. Another piece of unfinished work was a new key to the classification of vetches, nearly or quite completed, but awaiting the confirmation of this year's observation before publishing. His successor is not yet appointed. Among new lines of work undertaken by the station are: An investigation as to the causes and remedies for a disease of cattle on purely sandy areas, called the "Grand Traverse disease," the principal symptom of which is refusal of food and consequent inanition, a disease quite common in the northern central parts of the State; an investigation of the relation of the quality of the feed to the quality of the carcass in steers and lambs; and an investigation of the relation of fertilizers and other factors to the number and potentiality of the nodules on the roots of certain legumes.

Mississippi Station.—The branch station at McNeill was struck by lightning July 24, and the entire building was destroyed by fire. The station office and library were in the building, and the library was practically an entire loss. A second branch station has been located by the board at Holly Springs, but the work there will not be organized at present.

Missouri University.—H. W. Quaintance has been appointed instructor in economics, and during the next year will give a course of lectures in agricultual economics to

cover "the principles which underlie the prosperity of the farmer and of all other classes as far as they are dependent on agriculture."

Montana Station.—The station is just completing a large barn, which is built with an appropriation of $13,000. The building is an attractive one, and will be a great improvement over the dilapidated structures which formerly served for barns. The contract price was $11,400, not including the steam and water fittings, which will add about $500 more. The barn will accommodate about 75 head of stock, and is provided with cement floors, iron stable fittings, etc. A hog house and sheds for machinery have all so been put up.

Nebraska University and Station.—Good progress is being made in the erection of the $60,000 main building for the school of agriculture. The building will contain the executive offices of the experiment station, and offices and laboratories in animal pathology. The remainder will be devoted to instructional work of the school of agriculture. The completion of this building will leave the present station building to the departments of agriculture and agricultural chemistry, and give opportunity for equipping large laboratories for instruction and station work.

New Hampshire College and Station.—Harold H. Scudder has resigned his position as assistant chemist to enter newspaper work. Harry D. Batchelor, a graduate of this college in the class of 1903, has been appointed in his place. E. Dwight Sanderson, State entomologist of Texas, and entomologist of the Texas College and Station, has accepted the position of professor of entomology and zoology in the college and entomologist to the station, and will begin his duties November 1. He will succeed Clarence M. Weed, who has resigned to take charge of nature study work in the public schools of Lowell, Mass.

New Mexico College and Station.—John M. Scott, of the agricultural department, has been advanced to the position of first assistant, made vacant by the resignation of H. C. McLallen, who, as previously noted, has gone to the Wyoming Station. A. E. Lovett, a recent graduate of the Oklahoma Agricultural College, entered upon his duties as assistant in animal husbandry on July 1. F. O. Woodruff, formerly assistant chemist at the Nebraska Station, assumed the duties of assistant chemist the middle of June, vice C. L. Post, resigned. In June the pumping plant was run almost continuously for seven days and nights, throwing an average of 1,000 gal. per minute. The removal of this amount of water only lowered the surface of the water in the well 2 ft. below its position in one-day runs. A new 40-horsepower boiler and a 30-horsepower engine have been installed recently. This will allow the running of pumps on both wells at once, and raise the amount pumped to about 2,000 gal. per minute.

North Carolina College.—At the Summer School of the North Carolina College of Agriculture and Mechanic Arts, held during July, there was an enrollment of 977 teachers, of whom 477 took work in agriculture. Immediately following the Summer School a Farmers' Convention, with an enrollment of between 400 and 500 farmers, was held. This large attendance is an indication of the remarkable awakening in North Carolina along educational lines, and especially of the interest in agricultural education, which has been aroused during the past two or three years. As a further indication of this interest it is stated that the school authorities of several counties in the State voted to pay the tuition and most of the other expenses of such teachers as would attend this Summer School, but were prevented from carrying out their good intentions by a decision that the school funds could not legally be used in such a manner. According to a newspaper report, bids have been called for for the erection of an agricultural building at a cost of $50,000. Plans for the future development of the college campus have been made by a landscape gardener, and the new building will be located on his recommendation.

North Dakota College and Station.—W. B. Richards, of the Wisconsin Agricultural College, has been appointed assistant in animal husbandry in the college and station;

and F. J. Pritchard, a graduate of the University of Nebraska, who has lately been working under the agriculturist of the Nebraska Station, has been appointed assistant in botany and pathology.

Ohio University and Station.—H. A. Gossard, formerly of the Florida University and Station, has succeeded P. J. Parrott as entomologist, who, as previously noted, has gone to the New York State Station. A second annual meeting of the Ohio State Board of Agriculture, members of the faculty of the Ohio College of Agriculture, the farmers' institute lecturers of Ohio, and representatives of the agricultural press, was held at the station June 16 and 17, 1904. Addresses were made by John Hamilton, of this Office, and Cyril G. Hopkins, of the Illinois Station. S. H. Ellis, a former member of the board of control of the station and for 12 years its president, died on June 23 from injuries received in an accident.

Oregon College and Station.—At a recent meeting of the board, the department of botany, horticulture, and forestry was divided, the department of botany and forestry being established, with E. R. Lake in charge. The board also created a "station executive committee," consisting of the director, E. F. Pernot, and E. R. Lake, the duties of which are to direct and control the work of the station, subject to the approval of the president.

Rhode Island College and Station.—The college announces this year for the first time a four-year course in highway engineering, "intended to meet a definite and growing demand for men competent to build better roads." This is probably the first course of the kind ever offered in an American college. The work for this course in the freshman year differs little from the other courses in mechanic arts at the college. In the sophomore year the student begins the study of elementary surveying in the spring term. At the beginning of the junior year he is required to reach the college about two weeks in advance of the opening term in September and devote this time to surveying, including all the usual operations of simple triangulation, topographical, railroad, and highway surveys. During the college year in addition to English and mathematics, he will receive instruction in mineralogy and geology, with particular emphasis on road materials. Office work in platting and computation continues through the winter, and surveys are completed in the spring. The senior year is given over largely to highway engineering proper, and includes the study of stereotomy, masonry construction, strength of materials, theory of road building, hydraulics, highway bridges, and field practice. The recitation and laboratory work will be adjusted to accommodate the practice in construction which may occur in the fall or spring term. H. M. Soper, temporary assistant chemist, has resigned to accept a position elsewhere.

South Carolina College and Station.—J. S. Newman, vice-director and agriculturist, has resigned his connection with the college and station, to take effect next June. G. E. Nesom, veterinarian, has also resigned to accept the position of assistant chief of the Bureau of Agriculture in the Philippines.

Tennessee University and Station.—John R. Fain, assistant agriculturist, has resigned to become agriculturist at the Virginia Station and assistant professor of agriculture in the college; and P. O. Vanatter, plat expert, has resigned to accept a similar position at the Virginia Station.

Texas College.—J. W. Carson has succeeded E. R. Bennett in charge of the farmers' institute work of the State.

Virginia College and Station.—W. B. Alwood has resigned; his present address is Charlottesville, Va.

Washington College and Station.—N. O. Booth, horticulturist, has severed his connection with the college and station.

Wisconsin University and Station.—Walter S. Brown, of New York, has been appointed instructor in horticulture in the college of agriculture and assistant in horticulture in the station. He succeeds Frederic Cranefield, who, as already noted,

resigned to take the position of secretary of the Wisconsin State Horticultural Society.

Wyoming Station.—H. C. McLallen has resigned his position as assistant agriculturist, and will go to New Mexico, where he will operate a farm for himself. George E. Morton, a graduate of the Colorado Agricultural College and former student in the University of Wisconsin, has been appointed assistant in animal industry. B. P. Fleming, assistant in irrigation and irrigation engineer of the station, has been granted leave of absence for one year to pursue his studies and take an advanced degree in the East. Arrangements have been made with the Office of Experiment Stations for some cooperative work in drainage and the reclamation of alkali land at the station. It is expected that 20 acres of land which has been entirely destroyed by seepage and alkali will be drained and cropped for a period of 5 years. A research chemist, who will be assistant to the chemist of the university, will be appointed for work at the station the coming year. It is expected that the principal work taken up this year will be in studies of animal nutrition with stock foods raised at high altitudes. The station is located 7,187 ft. above the sea, and no work of the kind has been done heretofore in this country.

The past year the station has begun the breeding of horses experimentally, principally for the purpose of showing Western ranchmen how they can produce a general-purpose horse, and one suitable either for cavalry purposes or for work on the home ranch. It is thought the horse business in Wyoming can be made much more profitable than it is at present by improving the native stock with coach stallions and such warm blood as may be found necessary. To begin this work some coach stallions and grade mares were purchased last season. Unfortunately, glanders broke out in one of these mares, and the State veterinarian condemned and killed 3 mares and one of the station work horses in July. This will necessitate obtaining some new stock for breeding purposes.

Bureau of Chemistry, U. S. Department of Agriculture.—The order establishing the soil and fertilizer laboratory in the Bureau of Chemistry has been abrogated, and in lieu of this laboratory one to be known as the plant analysis laboratory has been established. The laboratory is charged with the examination of fertilizers and will collaborate in this work with the referees of the Association of Official Agricultural Chemists, and with the investigation of the constitution of plants. It is authorized to collaborate with the Bureau of Plant Industry in the chemical investigation of problems in which the two bureaus are mutually interested.

A leather and paper laboratory and a micro-chemical laboratory have also been established in this Bureau. The latter is charged with micro-chemical investigations relating to the investigations of the Bureau of Chemistry, and especially the examination of food products with respect to their composition and adulteration. To the leather and paper laboratory will be assigned analyses and investigations relating to tannins and tanning material, all technical problems of a chemical nature relating to the production of leather, chemical and physical examinations of papers with reference to their fitness for use in this and other Departments, and problems relating to the production of paper with a view to promoting the agricultural industries connected with the production of the raw materials and to the improvement of the quality of papers made.

Correspondence Courses in Agriculture.—The Columbian Correspondence College of this city announces 14 courses in agriculture, beginning with the opening of the current school year. These courses have with few exceptions been prepared by experts in this Department, and are as follows: (1) Plant life; (2) grasses and clovers, by F. H. Hillman, of the Bureau of Plant Industry; (3) soils, fertilizers, and manures, by L. J. Briggs, of the Bureau of Soils; (4) grain crops, by J. I. Schulte, of this Office; (5) poultry culture, by Horace Atwood, of the West Virginia College and Station; (6) vegetable gardening, by L. C. Corbett, of the Bureau of Plant Industry; (7) fruit

growing, by C. B. Smith, of this Office; (8) principles of stock feeding, by W. J. Spillman, of the Bureau of Plant Industry; (9) horse husbandry; (10) swine and sheep husbandry, by G. M. Rommel, of the Bureau of Animal Industry; (11) beef production, by E. V. Wilcox, of this Office; (12) veterinary science, by G. H. Hart, of the Bureau of Animal Industry; (13) the dairy herd and its care, by H. E. Alvord, of the Dairy Division, and (14) milk, butter, and cheese, by C. B. Lane, of the same division.

A New Agricultural School.—Oread is the name of a school for girls established at Worcester, Mass., in 1848, which has recently been moved to the Filston Farm, near Baltimore, Md. The institution has been reorganized and now includes a domestic science department for girls and women and a natural science department, including agriculture, industrial arts, and commerce, for boys and men. The subjects of instruction included under agriculture comprise drainage and irrigation, soils, crops, farm buildings and the home, marketing and accounts, horticulture, forestry, animal industry, dairying, poultry and bees, and veterinary science. The school has been endowed by Henry D. Perkey, who is also its president.

Agriculture at the British Association Meeting.—At the meeting this year of the British Association for the Advancement of Science there was for the first time in the history of the association a subsection devoted to agriculture, which was presided over by Dr. W. Somerville. The preliminary announcement of the meeting contained the following list of papers which had been promised: The Probable Error of Agricultural Field Experiments, an Analysis of the Soil by Means of the Plant, A. D. Hall, of the Rothamsted Station; The Influence of Sulphate as Manure upon the Yield and Feeding Value of Crops, and the Determination of the Availability of Insoluble Phosphate in Manures, T. S. Dymond; The Improvement of Wheats and Mendel's Laws, R. H. Biffen; The Clover Mystery—a Probable Solution of it, R. H. Elliot; Improvement of Clay Pastures through the Agency of Clovers, T. H. Middleton; and Chemical Composition of Root Crops, T. B. Wood and R. A. Berry.

New Society in France for Alimentary Hygiene and Nutrition of Man.—Recognizing the importance of studies on food and nutrition, a new scientific society has just been formed in France, which takes the name of The Society of Alimentary Hygiene and the Rational Nutrition of Man. The objects of this organization are the study and popularization of the best methods of scientific and economic nutrition of man in all conditions of life and of all ages, as well as the determination of the laws of hygiene in relation to nutrition and their social application. The society proposes to carry on studies in France and elsewhere, to found experiment stations and special laboratories, to offer prizes and other subsidies for the encouragement of work, to publish monographs and other technical works, to organize exhibitions and congresses, and to give scientific courses and lectures on its work and questions related to nutrition.

This organization was founded at the instigation of Dr. Ricard, senator from the Cote d'Or. The list of active members is limited to fifty; twenty associate members, French and foreign; one hundred corresponding members, and fifteen honorary members. It numbers among its founders some of the most representative men interested in physiological, hygienic, and medical studies.

This society is made up of five sections, namely, (1) Biological physics, (2) Physiology and biological chemistry, (3) Rational nutrition, (4) Chemical analysis of foods, and (5) Statistics of nutrition, including production, consumption of food, etc. Each section has a president and one or more vice presidents, Prof. L. Grandeau being president of the section of rational nutrition, and Prof. A. Gautier president of the section of physiology and biological chemistry. The president of the society is Dr. Ricard.

The founders of the society state that in determining upon its scope, methods, and objects they were very largely influenced by the nutrition investigations carried on in the United States, especially those of the Office of Experiment Stations, and, as

a recognition of this, Professor Atwater, chief of the nutrition investigations, was made an associate member.

The society publishes a journal entitled "*Revue de la Société Scientifique d'Hygiène alimentaire et de l'Alimentation rationelle de l'homme,*" which contains original articles and abstracts of current literature relating to the subjects in which the society is interested. Its foundation may be regarded as an illustration of the importance which the study of nutrition is assuming at the present time.

International Congress of Agricultural Mechanics.—It is proposed to hold an International Congress of Agricultural Mechanics at the Universal Exposition of Liège in 1905, under the patronage of the Belgian Government. The organization has, however, not yet been perfected nor the programme completed. A. Lonay, director of the provincial school of agricultural mechanics at Mons, is in charge of the preliminary arrangements. Among the topics which have been suggested for the programme are instruction in agricultural mechanics, testing stations for agricultural machinery, exhibition and tests of machinery, application of electricity, the traction automobile, and the establishment of a review of agricultural mechanics.

Personal Mention.—Alfred H. Allen, widely known for his treatise on Commercial Organic Analysis, a work in eight volumes, and the author of many papers on applied chemistry and food adulteration, died at Sheffield, England, July 14, at the age of sixty years.

The death is reported of Dr. Gustav Hempel, professor of agriculture at Vienna.

At the meeting of the British Association for the Advancement of Science, at Cambridge, August 17–24, and the International Physiological Congress at Brussels, August 29 to September 3, W. O. Atwater, in charge of the nutrition investigations of this Office, delivered addresses on the studies in the nutrition of man which are being carried on in this country.

Miscellaneous.—The committee authorized by the Texas legislature to pay a reward of $50,000 to the discoverer of a method for the extermination of the cotton-boll weevil has decided that no one has earned this reward.

The report of the Mosely Educational Commission, as given by Dr. Henry E. Armstrong in *Science* for August 5, while it expresses a high appreciation of the work being done for agriculture in this country by investigation and by the various agencies for the dissemination of information, contains statements which, doubtless unintentionally, fail to give full credit to the character of the work the experiment stations are doing. It says: "Much research work is also done in the State experiment stations; in the main, however, these serve to bring under the notice of farmers the importance of science to agriculture by demonstrating the value of methods of cultivation, manures, etc."

In commenting upon the pamphlet recently issued describing the collective exhibit of the colleges of agriculture and mechanic arts and the experiment stations at St. Louis, *Science* says: "It is probably the most complete and comprehensive display of its kind that has ever been attempted, and is believed to furnish an instructive exposition of a phase of educational and scientific effort which is rapidly extending and is already exerting a potential influence in developing the industries and resources of the country. It is safe to say that in no special field of education and research has there been greater progress during the past decade than along the agricultural, industrial, and technological lines represented by the land-grant colleges and experiment stations."

We learn from *Le Jardin* that a school of horticulture for women will be established at Cassel, Germany, this fall. In addition to the course in horticulture there will be courses in arboriculture, pomology, domestic economy, dairying, and poultry management. The school will be modeled after the best institutions of its kind, and supplied with modern equipment. It will not only teach the essentials of horticulture, but is designed also to supply professional gardeners.

The medical faculty of the University of Munich offers a prize for research on the nutrition of pigeons with chemically pure food stuffs (albumin, fats, carbohydrates, mineral salts, and water). In announcing the subject attention is called to the claim that mice can not be adequately nourished on such chemically pure foods, although there is a difference of opinion among investigators upon this point.

A board of agriculture has recently been established in the Bahamas, and a botanical station is to be started in connection with it. The station will be under the supervision of the Imperial Commissioner of Agriculture for the West Indies.

Through *Science* we note that Sir Thomas Elliott, for the British Board of Agriculture, in a reply to the Association of Chambers of Commerce, who urged the importance of establishing a national school of forestry, stated that through the agency of the commissioners of woods and forests a school of forestry had been established in the Forest of Dean, and that a movement is on foot for securing a suitable area of land in Scotland for the purpose of demonstrating scientific forestry. "The board has taken steps to secure the establishment of at least two lectureships in forestry in England, and some of the leading universities and agricultural colleges have been giving attention to proposals under this head. The agricultural departments of the University College of North Wales, Bangor, and of the Durham College of Science, Newcastle-upon-Tyne, appeared to offer special advantages as centers of instruction in forestry, and grants in aid of the establishment of schemes of education in the subject will be made by the board to those institutions. The board hopes that the arrangements thus made will result in a considerable improvement of the facilities available in this country for the acquirement of a knowledge of practical forestry."

Nature gives an account of the opening of the new hall of the Royal Horticultural Society in Vincent Square, Westminster, on July 22. The building includes a library, offices, council chambers, and a lecture room, in addition to the large hall in which the society will hold its fortnightly exhibitions. It was built to celebrate the centenary of the society, the funds being raised by subscription. The ultimate cost will be about £40,000, and of this amount £26,000 have been subscribed. It is said to be the intention of the society to provide scientific instruction, as well as practical training, in connection with the gardens at Wisley.

A laboratory for beet sugar manufacture has been opened in connection with the Agricultural High School at Berlin.

The chair of plant physiology, formerly occupied by P. P. Dehérain in the Museum of Natural History, has been changed by official decree to a chair of cryptogamic botany, and L. Mangin has been appointed its first occupant. The instruction in agronomy is continued by L. Maquenne.

O

EXPERIMENT STATION RECORD.

Vol. XVI. October, 1904. No. 2.

We are again called upon to pay tribute to the memory of one of the pioneers in agricultural education and experimentation in this country, who was in many ways a leader in the early period of development. The sudden and premature death of Maj. Henry E. Alvord caused widespread and deep regret, and especially among the institutions for agricultural education and research. First associated with one of these institutions as military officer in charge of the instruction in military tactics prescribed by the Morrill Act, he later gained distinction as a teacher in the more peaceful art of agriculture, and subsequently as an executive officer had the direction of both instruction and experimentation in agriculture.

Major Alvord's career was a varied one. He was born at Greenfield, Mass., March 11, 1844. Graduating from Norwich University, Vermont, with the degrees of B. S. and C. E., he entered the Army as a private in 1862, and before the close of the war had been advanced to the rank of major of the Second Massachusetts Cavalry. After the war he remained in the Regular Army as captain of cavalry until 1872, being assigned to service in the Southwest for quite a part of the time. It was during this period, from 1869 to 1871, that he was detailed as military instructor at the Massachusetts Agricultural College, being the first army officer detailed to an agricultural college for this service. While there he became much interested in the study of agriculture, and attended the various lecture courses on that subject which were then given at the college. Subsequently his tastes attracted him especially to dairying and the breeding of dairy cattle.

During the eight years following his resignation from the Army, while engaged as instructor in the scientific department of Williston Seminary at Easthampton, Mass., he found time to pursue his work in this new field, and by his writings and his public speaking gained considerable reputation as an agricultural expert. It was during this time that he wrote the American chapters of Sheldon's Dairy Farming. In the early days of the Chautauqua movement he was in charge of the agricultural branch of its reading courses, known as its "School of Farming." The three years' course of reading and examinations

which he worked out included experiments by the pupils and correspondence with the "director" of the course, and was probably the first correspondence course in agriculture undertaken in this country.

Major Alvord was greatly interested in the cooperative creamery system of butter making, which was attracting attention at that time, and became an ardent advocate of the cooperative system of dairying throughout New England. He established the first creamery east of the Hudson River, and was a leading spirit in the organizing of many others in Massachusetts, Vermont, and Maine.

On the establishment of the Houghton Farm Experiment Station in 1880 Major Alvord became general manager, remaining at its head until the project had to be abandoned in 1885 for lack of funds. In that year he was appointed professor of agriculture at the Massachusetts Agricultural College, where he remained for two years, resigning in 1887. He was elected director of the experiment station at Cornell University, upon its establishment under the Hatch Act, but declined the position to accept the presidency of the Maryland Agricultural College. He reorganized that institution and established the experiment station, occupying the position of president and director until 1892. He was afterwards temporarily in charge of the Oklahoma Agricultural College and Experiment Station, and went from there to the New Hampshire Agricultural College in 1894 as professor of agriculture, where he remained for a short time.

Few men were more prominently identified with the Federal legislation relating to the agricultural colleges and experiment stations than Major Alvord. He was prominent in the meetings preceding the formation of the Association of American Agricultural Colleges and Experiment Stations, and on the organization of that association he became chairman of its executive committee, discharging that office for eight years. During this time his judgment as a man of affairs, and his familiarity with methods of securing legislation, made him of great service in promoting the movements which resulted in the national endowment of the agricultural colleges and the experiment stations. He had what may be called the military habit or cast of mind. He made clear and detailed plans of work, was quick and firm in decision, and authoritative in manner and speech. He was thus qualified for leadership, and exerted a considerable influence in whatever enterprise he was engaged.

He was president of the Association of American Agricultural Colleges and Experiment Stations in 1894, which marked the termination of his connection with that body and with the institutions represented by it. In 1895 he was appointed Chief of the Dairy Division, which Congress had authorized to be established in the Bureau of Animal Industry of this Department. He organized this division and its work,

and was at its head at the time of his death. Here the same systematic and orderly business methods, attention to details, and conscientious and fearless attitude were evident in whatever he undertook. The efficiency of the division was due in large measure to his constructive and executive ability, and to his deep insight into the dairy conditions and needs of the country.

He was sent abroad in 1900 as a representative of this Department at the Paris Exposition, and was a member of the international jury of awards. In that year he traveled quite extensively in Europe studying dairy institutions and conditions. At the time of his death he was in attendance at the St. Louis Exposition, where he had been busily engaged upon the jury of awards. He was stricken with paralysis on the afternoon of September 28, and lingered in the hospital until October 1, when he died.

Major Alvord was a member of numerous scientific and dairy associations in this country and abroad, was a medalist of the Royal Agricultural Society of England and the British Dairy Farmers' Association, an "officer" of the National Order of Mérite Agricole of France, and was lately honored by his alma mater with the degree of LL. D. His genial nature and cordial manner won for him a very wide circle of friends; and his writings and his public services ranked him among the foremost authorities on dairying and dairy cattle in this country.

If any incentive were needed to induce young men to enter upon the study of agriculture, or any indication necessary to show the demand for men of agricultural training, it would be furnished by the record of the past summer. At hardly any time since the stations were organized and fairly running has there been a greater call for men of various grades and qualifications. A part of this call has arisen from the growth of agricultural instruction, and the reorganization of several institutions on a broader basis.

A notable feature of the present demand is the high degree of efficiency which is called for. In many cases specialists are desired, who bring to their work a combination of special training and experience not easily acquired at college. Frequently such men have had to be trained for the work after leaving college; and while this will probably be inevitable for certain positions, the enlarging of the facilities at the agricultural colleges, in teaching force and equipment, and the provision for more efficient post-graduate work, will enable the training in special lines to be carried much further.

It is gratifying to note that with the growing appreciation of trained men for various agricultural pursuits has come a greater interest in agricultural education on the part of young men. This is indicated in a rather striking manner by the attendance at many of the leading agricultural colleges this fall. As a rule, the number in the entering

class who have elected agriculture shows a marked increase, often far in advance of previous years. The University of Illinois, for example, reports 130 agricultural students in its entering class, as compared with 138 in the whole college of agriculture two years ago; Iowa Agricultural College entered 155, as compared with 128 last year; Massachusetts, 78; Michigan, 42 in the freshman and 66 in the subfreshman classes; Missouri, 60, as compared with 44 last year; Ohio, 45; and Texas, 60, as compared with 18 last year. The above figures apply to students in the entering classes who have elected the four-year courses in agriculture and horticulture.

Other colleges report a marked increase in the total number of agricultural students. At Cornell University the number has increased about 30 per cent, making the total 175; at the Alabama College the total is about 135, as compared with 125 last year; at Clemson College, South Carolina, 137—a considerable increase; and at the University of Wisconsin there are 88 students in the long course, against 60 last year.

While these numbers are not large relatively, they indicate a marked change over conditions a few years ago; and it should be noted that in the majority of cases the registration has increased in spite of more and more rigid requirements for admission, which are now as strict as for any other course in the institutions mentioned. The differentiation of the agricultural course is now so much more complete than formerly that in most instances the men who elect agriculture do so because they are seeking an agricultural education, and not because they are forced to take this course in order to get a training in general science, as was frequently the case a few years ago, or because it furnishes an easier road to a degree. This adds force to the figures presented above, and indicates that the placing of the agricultural course on a level with other college courses in point of entrance requirements and grade of work is meeting with very encouraging results.

The two-year courses and the short winter courses are serving a most admirable purpose, and are increasing the army of trained agriculturists, who put the teachings of the agricultural colleges and the experiment stations, and other agencies for agricultural advancement into practical application. But the regular college course must be looked to to furnish the leaders in the higher agricultural work, and to man the colleges, stations, and other agricultural institutions. That there is still abundant encouragement to pursue this course, and to follow it by post-graduate work in special lines, is evidenced by the difficulty in meeting the demand for properly equipped men in various lines of administrative, educational, and experimental work.

ANNUAL MEETING OF THE AMERICAN VETERINARY MEDICAL ASSOCIATION.

E. V. Wilcox, Ph D.,
Office of Experiment Stations.

The forty-first meeting of this association was held in St. Louis August 16–19, 1904. The attendance was larger than at any other meeting in the history of the association, and the interest manifested in the discussion of papers was very gratifying.

On the first day the usual order of business was observed, beginning with an address of welcome by a representative of the Chamber of Commerce of St. Louis, followed by a response by W. H. Dalrymple, the reports of committees and outgoing officers, as well as of State secretaries, and closing with the election of the following officers for 1904–5: President, M. E. Knowles; vice-presidents, J. G. Rutherford, E. M. Ranck, G. W. Dunphy, G. R. Young, R. P. Lyman; secretary, J. J. Repp; treasurer, W. H. Lowe.

The presidential address by R. R. Bell contained a discussion of the present status of the veterinary profession. The speaker called attention to the observed fact that veterinarians at present receive more respect from their clients and from the world at large than ever before. This condition is apparently due to improvement in the character and qualifications of the veterinarians themselves. The horse is also valued more highly than ever, despite the popularity of automobiles, and higher prices are willingly paid for professional services in keeping the horse in health. Veterinarians exercise a great influence in the prevention of animal plagues, particularly those which are common to animals and man.

Reviewing the history of veterinary schools and institutions, the speaker urged that diplomas should be standardized so as to have a more uniform value. To this end he recommended the reestablishment of the association of veterinary faculties in cooperation with the association of veterinary medicine.

The committee on intelligence and education, E. B. Ackerman, chairman, reported that veterinary catalogues had been collected and a long list of questions relative to veterinary courses addressed to twenty veterinary colleges. Detailed comments were made on each of these institutions, and suggestions were made regarding needed improvements in their courses of instruction. In many institutions the courses were considered very defective, and the institutions themselves were severely criticised.

The committee on diseases, C. H. Higgins, chairman, presented a report covering several subjects, edited by different individuals. Actinobacillosis was reported by Doctor Higgins as having occurred in various parts of Canada. The germ in five outbreaks which were studied in Canada was not very virulent. Laboratory animals died within 12 to 25 days after artificial inoculation. The lesions were very characteristic when examined under the microscope. It was considered an easy matter to distinguish by the gross symptoms between actinobacillosis and actinomycosis. E. S. Wheeler reported that ovarian cysts had been found to be the cause of nymphomania in cows in many cases, although pathological conditions do not always cause nymphomania. In the majority of cases a cure was brought about by operation and removal of the cysts.

The history of infectious abortion was discussed in considerable detail by V. A. Moore, who considered it one of the most important diseases of cattle. It is characterized by lesions of the uterine and fetal mucous membranes. The colon bacillus was not found in any of 14 cases, while numerous micrococci and streptococci were observed. Artificial infection of experimental animals was unsuccessful, despite numerous attempts. It was found, in conversation with dairymen, that the contagiousness of the disease is not generally admitted. In the speaker's experience contagious abortion yields readily to disinfectant treatment. The uterine and fetal lesions reported by European investigators were not observed in the United States.

A. R. Ward presented a report on poultry diseases, calling attention to their great importance and to the recent establishment of a poultry experiment station in California. Poultry diseases require more study in order to obtain a thorough knowledge of their nature. The tuberculin test is not reliable when applied to fowls, on account of the great variation in temperature in these animals. Tuberculosis is apparently spreading among fowls by traffic in laying hens. The speaker recommended the isolation of chickens from old hens, and maintained that tuberculosis was not transmitted through the eggs. Fowl cholera was mentioned as the next most important disease of chickens, which may be controlled by thorough disinfection and by the destruction of dead fowls.

The committee on pharmacopœia, E. M. Ranck, chairman, reported that after careful consideration of this question it was considered impracticable to publish a book on the subject of veterinary pharmacopœia. The work required too much time and money to be taken up officially by the association. The committee was therefore discontinued.

The committee on mutual aid association reported that the assessment plan of mutual aid to veterinarians was considered impracticable, and the committee was therefore discharged.

The secretary, J. J. Repp, in his report stated that the resident secretaries had devoted an unusual amount of time to securing additional members to the association and improving the programme of the annual meetings. The plan of assigning the opening of the discussion of each paper to two members was adopted for the purpose of stimulating the discussion and awakening a wider interest in the papers. It was recommended that the executive committee at each meeting name certain subjects to be discussed at the next annual meeting.

A number of State secretaries made reports regarding the veterinary conditions in different parts of the country. In these reports mention was made of progress in State laws for the control of animal diseases, laws regulating veterinary practice, veterinary education, the general health of animals, and the most noteworthy animal diseases during the year. Among the latter were verminous bronchitis in calves in California, glanders in Florida and Kansas, influenza in Kentucky, rabies in Michigan, forage poisoning in Mississippi, cattle mange in Nebraska, and Texas fever in Tennessee. In Arizona the presence of swamp fever was noted in one valley. This disease is believed to be identical with that observed in Minnesota and Manitoba. In Montana a disease of sheep known as crusta labialis has been observed in various counties. Experiments in immunizing cattle against tuberculosis have been continued in Pennsylvania, 100 animals being used for this purpose. The results thus far obtained are very promising, and a State commission composed of 18 men has been appointed for the purpose of making a further investigation of this problem.

Dr. K. Tsuno, veterinary representative of the Japanese Empire, was present at all the sessions and presented a report on animal diseases and quarantine laws in Japan. So-called farcy of horses prevails to a considerable extent in that country, and infected animals do not react to mallein. The speaker recommended that the disease be preferably called false farcy. Before foreign animals were allowed to enter Japan there was no rabies, farcy, or other serious contagious disease among Japanese native animals. Foot-and-mouth disease was introduced from the Asiatic continent, and cattle plague from Korea in 1892. Sanitary measures and quarantine laws have recently been passed, but until 1897 these laws were not well calculated to prevent the introduction of serious diseases. Tuberculosis is not known in native Japanese cattle. When introduced by foreign cattle it has been found to yield to the Bang method of prevention.

L. A. Merillat presented a paper on When to Operate. Attention was called to the desirability of papers on veterinary surgery, to be presented before the annual meetings of the association. The dangers of hasty operation were outlined, and the value of surgery was held

to depend largely upon being applied with caution. All operations entailed certain dangers and should not be called trivial. The conditions surrounding each case should always be carefully noted before operation. Care was urged in the use of anesthetics. Detailed suggestions were made regarding operations in pneumonia, periodic ophthalmia, fistula, quittor, luxation of the patella, goiter, roaring, and other surgical diseases. The ordinary clinics as held at the annual meetings of the association were severely criticized, for the reason that the operations are usually performed under unsatisfactory conditions, so that they do not represent the best practice of veterinary surgery.

A paper was read by J. M. Parker on Creeps, an Osteomalacial Disease of Cattle. Creeps appears in winter and early spring in certain parts of Texas. Pregnant cows appear to be most susceptible. In some localities 50 per cent of such cows are affected. Creeps is apparently identical with osteomalacia. The soil and forage conditions of the locality in which the disease occurs were carefully described. No breeds of cattle are especially susceptible. The first symptom of the disease is lameness. Poor animals are most often affected. Bones of the legs and the ribs break easily. The fat of affected animals tastes like pork, and the bone marrow becomes yellow and hemorrhagic. The etiology of the disease is unknown and no successful treatment has been devised except a palliative one, consisting of the use of better rations.

Immunization against tuberculosis was discussed by L. Pearson. Work along this line has been carried on for a number of years in Pennsylvania. More than 100 cattle have been used in these experiments and some of them have been kept under continual observation since 1900. These cattle have been treated in various ways by living and dead tubercle bacilli, virulent and nonvirulent for cattle. It has been found possible by means of five inoculations of human tubercle bacilli to immunize cattle so that they remain alive for one year when exposed to natural infection. Immunized cattle also stand large doses of virulent cultures without developing tuberculous lesions, except after the use of immense doses. The immunity thus produced is very high, but not absolute. Some time is required for its production. The method is considered to be still in the experimental stage, but is believed to be of practical application.

G. H. Glover presented a discussion of the cattle-mange problem of the West. Scab of cattle is becoming more and more serious in Colorado. In some localities a loss of 15 per cent is reported. An outline was given of plans for future work in controlling this disease, including a discussion of the conditions which prevail on the range. Mange shows its worst symptoms during times when feed is poor and animals in bad condition. Apparently negative results were obtained in attempting to transmit the disease to healthy cattle. The difficul-

ties of controlling it in range cattle were outlined. Cattle may easily become reinfected after the mange mites have been destroyed by dipping. Compulsory dipping before shipment is considered an unnecessary hardship for the cattlemen of Colorado.

N. S. Mayo discussed the same problem as it occurs in Kansas. He considered quarantine and dipping as absolutely necessary. The cage and the swimming-vat methods have been employed. The swimming vats should be from 40 to 60 feet long. The most effective, cheapest, and least injurious dip is the homemade lime-and-sulphur dip. Coal-tar dips are considered objectionable on account of their odor, the variation in strength, the irritation which they cause to the skin, and their excessive cost. Most of them cost from two to three times as much as the lime-and-sulphur dip. It was recommended that the dip be made so as to show a slight excess of sulphur. Cattle should be dipped twice, ten days apart, in the spring, with the dip at a temperature of 110° F. Cotton-seed oil was found to be effective as a dip, but was rather too expensive. Hand treatment, in the speaker's opinion, was of little value. Well-fed cattle frequently become affected. Apparent recovery is always followed by a recurrence of the scab, and infection is hard to detect during the summer months. Proprietary medicines are considered a nuisance in connection with this disease.

In discussing this paper, J. G. Rutherford also stated that fat cattle could become infected. In northwest Canada it is impossible to dip cattle in the spring. The Canadian regulations require that veterinary officials collect and dip stray cattle or cattle of owners who, for any reason, fail to dip. The lime-and-sulphur dip was considered the most effective, but hand treatment also gave good results under certain circumstances.

M. E. Knowles stated that hand treatment with dynamo oil had been successful with him in 4,000 cases. To the dynamo oil about 2 per cent of sulphur is added. The best method, in the speaker's experience, for keeping the dip warm was by the use of a caloric transformer as employed by brewers. The dipping vats in Montana contain from 10,000 to 30,000 gallons of water. N. S. Mayo reported that he had had better results with ordinary steam pipes than with the caloric transformer, but preferred a tank furnace, and strongly recommended a dip formula containing 12 pounds of lime and 20 pounds of sulphur.

A. T. Peters found by extensive correspondence with cattle raisers that a very low percentage of sulphur was used in some homemade dips. A formula has been devised for the preparation of a lime-sulphur dip which may be manufactured by commercial firms so as to have a standard strength.

A communication was received from A. Liautard on needed reforms in veterinary education in the United States. The author reviewed

the work of the veterinary schools in this country, calling attention to the difficulties in the way of reforms. The possible influence of the association in veterinary education was outlined. Comments were made on the entrance requirements and length and thoroughness of the curriculum of various veterinary schools, which it was held showed too great variations. The instruction as outlined in catalogues is often altogether too pretentious. too much subdivided, and the course too short, with irregular graduate courses. The courses in a few of the better veterinary schools were approved as excellent.

In discussing this paper, J. Law stated that the author was qualified to criticise American veterinary schools from his extensive experience in this country and abroad. Attention was called to the fact that educational institutions are well supported both by brains and money in this country, and that students' fees are inadequate to maintain veterinary schools on a suitable basis. Veterinary practice demands an education equal to that of any other profession. The standards may be fixed by State legislatures, and the association can recommend but not enforce uniformity in veterinary schools.

A. R. Ward presented a paper on Roup in Fowls. Roup has been shown to be distinct from human diphtheria. The anatomy of the chicken's head is considered of great importance in relation to the occurrence and treatment of the disease. During the development of roup the suborbital sinus becomes greatly distended, and may be opened to relieve the most serious symptoms. The remedies for roup must be cheap in order to be of general application. The head may be dipped in a 2 per cent solution of potassium permanganate for 10 to 15 seconds. A 2 per cent solution of creolin affected a cure in only 1 out of 12 cases. In another test chickens were given a permanganate treatment 6 times during 16 days, without good results. Roup is widely distributed in California. In one flock, 60 per cent of the fowls were affected. In treating this flock a 2 per cent solution of copper sulphate gave no results. A similar failure resulted in the use of turpentine and spirits of camphor, while kerosene appeared to cure about one-half of the cases. In one outbreak, 91 hens were treated 3 times with kerosene, with the result that 61 per cent were cured. Kerosene thus appears to be the best remedy for roup. Tincture of iodin was also quite effective in certain outbreaks of the disease. Roup is not easily communicated by intimate association. It was not found possible to prevent its spread by the use of corrosive sublimate in the drinking water in proportion of 1 to 2,000. Quarantine and isolation of sick fowls gave the best results, in connection with thorough disinfection.

In discussing this subject, V. A. Moore stated that in his practice the best results have been obtained from the thorough application of disinfection. From an etiological standpoint roup appears not to be a

specific disease, but due to various causes. It is found impossible to transmit the disease by artificial inoculation.

In a paper on the clinical study of blood, V. A. Moore called attention to the importance of such study in the diagnosis of human and animal diseases. The author's work was largely confined to the horse. It was found desirable to take blood samples from the capillaries of the skin to determine the number of red blood corpuscles. The amount of hemoglobin was then determined. Special attention was given to the study of normal variations. The red blood corpuscles were found to vary from 7,000,000 to 9,000,000 per cubic millimeter, and the total leucocytes from 4,000 to 6,000, while the average number of red blood corpuscles were 7,944,000 per cubic millimeter. In suppurative process the polynuclear cells increase, while the eosinophiles decrease in numbers. In pneumonia the latter cells completely disappear, while in cachexia the red corpuscles may become as few as 2,000,000 per cubic millimeter. Surgical operation under chloroform has the effect of greatly increasing the number of red corpuscles. A differential count of the blood elements is considered of great assistance in diagnosis.

F. F. Brown read a paper on Mallein as a Cure for Glanders. Mallein was used in testing 301 horses which were killed for glanders in Kansas City in 1903. In 149 cases the temperature reached 102° F. or more, and varied from that to 106° F. Sixty-five of these animals were again tested after 30 days, and in 64 of them the temperature reached 103° F. or more. From subsequent history of these and other cases the speaker believed that glanders may be cured by the use of mallein.

In discussing this question, C. H. Higgins stated that 3,147 horses had been tested in Canada, with a reaction in 592 cases. A large percentage of these horses ceased to react in later tests. In Canada the second test is applied after 40 days, the third after 100 days, and the fourth after 190 days. J. G. Rutherford, continuing the discussion, urged care in discharging ceased reactors. Some Canadian restrictions are removed in case of these animals; but horses which react with a temperature of 105° F. at the first test seldom recover. Of 730 reacting horses, 181 ceased to react after subsequent tests; but this percentage is not considered sufficient to pay for repeated inspections and tests. It is recommended, therefore, that all reacting horses be killed. In the future the Canadian Government will pay no indemnity for cases with clinical symptoms, while reactors without clinical symptoms will be paid for at the rate of two-thirds of their value.

C. C. Lyford discussed the subject of quittors and sidebones. These diseases, in the speaker's opinion, can not be cured with medicaments. It is recommended that the lateral cartilage be excised. The foot must be previously prepared by softening. Where possible, the division of

the coronary band should be avoided. After operation the wound may be dressed with witch-hazel and boracic acid. As a result of this operation, the horse is unfitted for work for a period of from 4 to 6 weeks.

C. H. Jewell discussed veterinary medicine and surgery in the Philippines. Surra first occurred in the Philippines in 1901. The disease is carried chiefly by stable flies and affects about 50 per cent of the caribao. Affected horses show a temperature of 105° F., and the blood parasite is readily demonstrated. The symptoms of the disease were described in detail. No success was had in destroying the blood parasite by the use of drugs. Contagious lymphangitis due to a species of cryptococcus is frequently miscalled farcy. The affected animals should be immediately isolated and the nodules cauterized and subsequently treated with antiseptics. Notes were also given on canker, thrush, glanders, eye diseases, pneumonia, and wounds.

The conditions of veterinary practice in the Philippines were also discussed by J. H. Gould. Sanitation in the Philippines is very poor, and the natives are unable to pay for veterinary services. As a rule, therefore, it is necessary for the veterinarian to have some source of income other than ordinary practice.

A simple and effective live-stock sanitary law was discussed in a paper by A. W. Bitting. In Indiana the decision of the State veterinarian is final in all cases, and this law has been found to be wholly satisfactory. In discussing the paper, J. I. Gibson stated that he considered the Indiana law an effective one, but suggested that the State veterinarian ought not to apply treatment in the case of ordinary diseases. It was also suggested in discussing the subject, that the State veterinarian should receive the support of some of the live-stock board in order to lend his decisions more weight and to prevent the development of litigation in disputed cases.

G. E. Nesom discussed the comparative virulence of the Texas-fever parasite. Texas fever frequently occurs among tick-free native cattle in South Carolina. A study of the ticks in certain localities showed that they were not virulent on account of the presence of a nonvirulent form of *Pyrosoma bigeminum*. The virulence of this parasite may be increased by passage through generations of ticks on different cattle. Its virulence may also be diminished in ticks which live under unfavorable conditions.

In discussing this paper, J. C. Norton referred to an outbreak of Texas fever in Arizona, during which evidence was obtained to show that the virulence of the Texas-fever parasite may be entirely lost under certain conditions.

RECENT WORK IN AGRICULTURAL SCIENCE.

CHEMISTRY.

Estimation of nitrogen by Kjeldahl's method (*Trans. Guinness Res. Lab., 1 (1903), pp. 13–16; abs. in Jour. Chem. Soc.* [*London*], *86 (1904), No. 500, II, pp. 443, 444*).—A distillation apparatus for use in Gunning's modification of the Kjeldahl method is described, and precautions to be observed in order to prevent loss of nitrogen when dealing with bulky materials are given.

Distilling apparatus for the Kjeldahl method of determining nitrogen, E. Blanck (*Chem. Ztg., 28 (1904), No. 34, p. 406, fig. 1; abs. in Jour. Chem. Soc.* [*London*], *86 (1904), No. 500, II, p. 444*).—The digestion flask is fitted with a rubber stopper double-bored to receive a tap funnel through which the alkali and the potassium sulphid are introduced, and for connection with the distillation apparatus. At the beginning of the distillation water is allowed to run through the condenser at full speed, but toward the end it is made to run slowly while the contents of the flask are more vigorously boiled.

A Kjeldahl apparatus, M. Siegfried (*Ztschr. Physiol. Chem., 41 (1904), No. 1–2, pp. 1, 2, pl. 1; abs. in Jour. Chem. Soc.* [*London*], *86 (1904), No. 500, II, p. 444*).—A device driven by water or electric motor for imparting a swinging motion to Kjeldahl flasks to prevent bumping is described.

A new method of estimating hippuric acid, T. Pfeiffer, C. Bloch, and R. Riecke (*Mitt. Landw. Inst. Univ. Breslau, 2 (1903), No. 2, pp. 273–293*).—A method is proposed which, according to the authors, gives very accurate results.

Concerning the estimation of fat in animal tissues, feeding stuffs, and the like, T. Pfeiffer and R. Riecke (*Mitt. Landw. Inst. Univ. Breslau, 2 (1903), No. 2, pp. 295–304, fig. 1*).—A form of fat-extraction apparatus is described, which, according to the authors, gives very satisfactory results.

Methods of determining sulphur in organic substances, M. E. Pozzi-Escot (*Rev. Gén. Chim. Appl., 7 (1904), pp. 240, 241; abs. in Chem. Centbl., 1904, II, No. 1, p. 62*).—The author points out the disadvantages of various methods heretofore proposed. He describes a method of oxidation by means of nascent chromyl chlorid, which gives good results with volatile compounds. In this method 1 gm. of the substance is mixed in a 500 cc. flask with 10 to 15 times its weight of pure dry chromic acid. Then 20 to 25 cc. of pure and highly concentrated hydrochloric acid is added, shaken vigorously for a few minutes, and allowed to stand 20 to 30 minutes. The flask is connected with a reflux condenser and heated at boiling temperature for 10 minutes. If the chromic acid is in excess, the sulphur is completely converted into sulphuric acid by this treatment.

The determination of argon in atmospheric air, H. Moissan (*Bul. Soc. Chim. Paris, 3. ser., 31 (1904), No. 12, pp. 729–735*).—Methods of taking samples of air and determining argon are described, with results of examinations of samples of air from widely separated parts of the world. The method is based upon the complete absorption of oxygen and nitrogen by metallic calcium. A measured quantity of approximately 1 liter of air is drawn through 2 tubes maintained at a low red heat, the first of which contains a mixture of quicklime and magnesium and the second

about 1 gm. of calcium in very small crystals. The residue of argon is measured over mercury in an apparatus similar to that of Regnault and Schloesing. In the determinations reported the proportion of argon varies from 0.9305 to 0.9492 per cent.

Conversion tables for calculating fertilizer and feed-stuff analyses, H. B. McDonnell (*Maryland Agr. Col. Quart., 1904, No. 24, pp. 16*).—This is a reprint of tables first published in Bulletin 30 of the Maryland Station, the tables for potash having been recalculated, using the revised official factor for K_2O from K_2PtCl_6.

The valuation of feeding stuffs, T. Pfeiffer (*Mitt. Landw. Inst. Univ. Breslau, 2 (1903), No. 2, pp. 257–271*).—A method of calculating the value of feeding stuffs, taking into account their manurial value.

Investigation of the bodies called fiber and carbohydrates in feeding stuffs, with a tentative determination of the components of each, P. Schweitzer (*Missouri Sta. Rpt. 1903, pp. 8–26*).—Previously abstracted from another source (E. S. R., 15, p. 848).

A comparison of the halogen absorption of oils by the Hübl, Wijs, Hanus, and McIlhiney methods, L. M. Tolman (*Jour. Amer. Chem. Soc., 26 (1904), No. 7, pp. 826–837*).—This is a brief account of work previously noted from another source (E. S. R., 15, p. 438).

The determination of water in substances that are to be afterwards extracted with volatile solvents, R. M. Bird (*Jour. Amer. Chem. Soc., 26 (1904), No. 7, pp. 818–826, pl. 1, fig. 1*).—An apparatus devised for the purpose of avoiding the transferring of butter from the drying dish to the extraction apparatus is described and illustrated. While devised for use in butter analysis, the method is also applicable to various other substances, and is believed to be as accurate as the official method of the Association of Official Agricultural Chemists, and to require much less time.

Contribution to the question of Gottlieb or Adams, L. F. Rosengren (*Rev. Gén. Lait, 3 (1904), No. 15, pp. 337–344*).—The experimental work of the author agrees with results published by others, that when milk has been subjected to considerable agitation, as in churning, marked differences are found in the determination of fat by the Gottlieb and Adams methods.

Two theories have been advanced to explain this result, namely, that the small fat globules are encased in dried casein, which prevents their extraction by ether, and that other substances than fat are extracted. The author holds to the former view. The fat obtained from a large number of samples analyzed by the Gottlieb method was collected and dissolved in ether, the insoluble matter amounting to 0.002 to 0.004 per cent of the original milk. This residue was found to be very different from the nitrogenous material obtained by Storch from cream by repeated washing with water and centrifuging.

The residue was found to consist almost entirely of lecithin, while in the material obtained by the method of Storch the nitrogen content varied between 11 and 14 per cent. The material obtained by the method of Storch is, therefore, not believed to be the cause of the higher results obtained by the Gottlieb method.

The cryoscopy of milk, J. Winter and E. Parmentier (*Rev. Gén. Lait, 3 (1904), Nos. 9, pp. 193–200; 10, pp. 217–224; 11, pp. 241–247; 12, pp. 268–274*).—An extended study was made of the application of cryoscopy to the examination of milk. Historical notes are given and the technique of the method employed is described. Numerous determinations of the freezing point of pure and adulterated or modified milk are reported. Cryoscopy is believed to have many practical applications in the examination of milk and in the prevention of adulteration.

Determination of citric acid in milk, M. Beau (*Rev. Gén. Lait, 3 (1904), No. 17, pp. 385–396*).—The author reviews the literature relating to the presence of citric acid in milk and describes a modified method used by him, based upon the oxidation of the citric acid by potassium permanganate and the precipitation of the resulting

product by mercuric sulphate, the precipitate being collected, dried, and weighed, or, preferably, dissolved in hydrochloric acid and the mercury determined volumetrically in the solution.

Determination of dirt in milk, M. BALLO (*Oesterr. Chem. Ztg., 7 (1904), No. 5, pp. 101, 102*).—The milk is filtered through fine bolting cloth previously moistened with water, the dirt is washed with water and with alcohol and ether, and transferred to a weighing dish and weighed.

The strength of commercial formaldehyde, E. F. LADD (*North Dakota Sta. Rpt. 1903, pp. 35, 36*).—An examination of a number of samples of commercial formaldehyde showed that the strength was frequently below the standard of 40 per cent.

The adulteration of drugs, L. F. KEBLER (*U. S. Dept. Agr. Yearbook 1903, pp. 251–258*).—The author cites early instances of the adulteration of drugs, and discusses factors affecting the quality of drugs, importance of purity of drugs, extent and nature of adulteration, and the progress being made in the investigation of drugs and the establishment of standards.

Report of the State chemist of Florida, 1903, R. E. ROSE (*Florida Mo. Bul., Dept. Agr., 13 (1904), No. 89, pp. 71*).—This report deals mainly with the results of fertilizer inspection during 1903, but contains also analyses of miscellaneous substances, foods, waters, ores, etc.

BOTANY.

Report of the botanist, H. L. BOLLEY (*North Dakota Sta. Rpt. 1903, pp. 42–58, fig. 1*).—A report is given of the condition of the department of botany, its equipment and work, particular attention being called to the test of native and other grasses, studies of elevator samples of wheat, the adulteration of formaldehyde and formaldehyde treatment of grains, flax studies, particularly the treatment of flax wilt, and some physiological experiments with trees.

The grass studies, which were begun in cooperation with this Department, were not fully carried out on account of the inability of the station to provide the necessary funds, but the preliminary investigations showed that meadow fescue, rough fescue, western brome, and short-awned brome grasses, under the adverse conditions of the experiment, were of particular value for the State. From the studies made with elevator samples of wheat it is apparent that the average dockage for weed seed, dirt, etc., is considerably higher than the investigation showed necessary. Complaints are mentioned of the failure of the formaldehyde treatment of seed grains for the prevention of smut and this failure is laid to the use of adulterated or weak solutions of formaldehyde.

The experiments for the control of flax wilt have been continued and investigations are in progress by which it is hoped to discover strains of flax immune to the fungus. In connection with these investigations it has been found that the fungus remains in the soil for a longer period than hitherto supposed, and in connection with it is associated an undescribed species of Colletotrichum. This phase of the investigation is to be the subject for a future publication.

The physiological experiments with trees consisted of an attempt to stimulate the tree to growth or to render it less subject to disease through the artificial feeding of the tree by means of liquid solutions injected into the trunks. These investigations have not been carried on sufficiently to establish any positive conclusions, but a number of factors have been determined, among others—under similar conditions a tree seems to feed at about a uniform rate day or night; the rate is influenced by atmospheric temperature, moisture, water supply in the soil, strength of solution applied, etc. Trees vary in their rate of feeding with regard to variety and the natural growth, size, etc. Chemical substances are carried to the utmost parts of trees in a few hours, substances being detected within 10 hours in the topmost

twigs of cottonwood trees 30 to 45 ft. high. The diffusion of liquids radially through the trees is much slower than the vertical movement. The killing effect of solutions appeared to be in direct relation to their strength. The effect of solutions on parasitic disease is inconclusive.

A museum of economic botany, W. G. FREEMAN (*New Phytol., 2 (1903), No. 10, pp. 228-234*).—An account is given of the author's conception of the objects and uses of a museum of economic botany in which he states that "a museum of economic botany should be devoted to illustrating the source, geographical distribution, collection, manufacture, properties and uses of vegetable products, and the conditions controlling their production and utilization, the means employed being specimens, photographs, maps, descriptive information, commercial data, etc.

"The products may be grouped according to (1) their botanical relationships, (2) their uses, (3) their country of origin. In museums devoted to the products of only one country, the employment of the second method appears the most useful. In museums of a wider scope the adoption of the first method has a special interest for the botanist. The second and third methods appear of almost equal value for commercial purposes, the advantage being with the geographical system if the museum is extensively used to illustrate the products and resources of particular countries and the conditions controlling botanical enterprise."

A dictionary of the plant names of the Philippine Islands, E. D. MERRILL (*Philippine Dept. Int., Bureau Govt. Lab. [Pub.], 1903, No. 8, pp. 193*).—The author has compiled a dictionary of the native plant names of the Philippine Islands, the plants being arranged alphabetically by the native names and in a second part alphabetically by their scientific names. The names given are those of 12 or 15 of the more common dialects spoken in the islands.

Philippine agricultural products, F. LAMSON-SCRIBNER (*Ann. Rpt. Philippine Com., 1903, pt. 2, pp. 668-676*).—Alphabetical lists based on the popular and scientific names of the species are given of some of the agricultural products of the Philippines, together with brief descriptions of the plants, their distribution and uses. This information is based upon the author's observations, as well as compiled from the reports of correspondents.

The American element in the Philippine flora, E. D. MERRILL (*Philippine Dept. Int., Bureau Govt. Lab. [Pub.], 1903, No. 6, pp. 19-36*).—A brief review is given of the Philippine flora, in which the author attempts to show the occurrence of American species in the Archipelago. Among the more prominent plants of American origin are a number of economic and ornamental plants which were introduced, principally through Mexico. In addition to these a second group of plants is present most of which are distributed as weeds. These owe their introduction largely to seeds which have been accidentally introduced in packing material.

New or noteworthy plants, E. D. MERRILL (*Philippine Dept. Int., Bureau Govt. Lab. [Pub.], 1903, No. 6, pp. 5-18*).—Descriptions are given of a number of new or noteworthy species of plants many of which are forest trees of considerable importance.

The cultivation of drug plants in the United States, R. H. TRUE (*U. S. Dept. Agr. Yearbook 1903, pp. 337-346, pls. 3*).—Attention is called to the demand for medicinal substances of plant origin, and at the present time the United States is said to be importing many products derived from plants already well established in this country and in some cases occurring as noxious weeds.

A summary is given of crude-drug importations and of drug substances of vegetable origin, from which it appears that during the year 1902 the imports of these two classes of products amounted to a total of $16,041,818.42. Attention is called to a number of common drug plants and suggestions given for their cultivation.

Experiments on the development of the bacteria of leguminous plants in soils independent of the presence of the specific host plant, STEGLICH (*Ber.*

Tät. Landw. Abt., K. Vers. Stat. Pflanzenkult., Dresden, 1903, p. 4).—Experiments with serradella on inoculated and uninoculated soil are reported, which show that root tubercles developed in the uninoculated soil, although the nodules were apparently larger and more numerous in the inoculated soil and the yield was also somewhat larger.

Experiments on the effect of copper sulphate in the soil on plant growth, Steglich (*Ber. Tät. Landw. Abt., K. Vers. Stat. Pflanzenkult., Dresden, 1903, p. 4*).—Copper sulphate was applied to soils in pots two years in succession, at rates of 40, 80, and 160 gm. per square meter of surface, without injurious effects on fruit trees and strawberries. Injury resulted, however, when like amounts were applied in the field to potatoes, beans, etc.

Two types of intramolecular respiration of higher plants, A. I. Nabokikh (*Zhur. Opuitn. Agron.* [*Jour. Expt. Landw.*], *4* (*1903*), *No. 6, pp. 696–713*).—The experiments of the author lead him to distinguish two types of intramolecular respiration of higher plants, i. e., typical alcoholic fermentation, and alcoholic fermentation of glucose with the decomposition of organic acids. The typical alcoholic fermentation is shown in experiments with glucose, experiments of long duration in water, and, probably, the cultures in mannite of long duration.

In these series of cultures the ratio between carbon dioxid and alcohol was observed to closely correspond to that of alcoholic fermentation. In the combination of alcoholic fermentation of glucose with the decomposition of organic acids, the most striking examples were observed in experiments with weak solutions of lactic acid. It was found that during the entire time of the experiment a comparatively large quantity of acid was lost, while at the same time the amount of alcohol was found to be 12 to 35° lower than is characteristic for the alcoholic fermentation.

A series of parallel experiments in water and peptone showed that the latter, like glucose, is capable of considerably increasing the energy of the intramolecular respiration of peas. The alcoholic coefficient is here close to the normal for alcoholic fermentation, averaging 102 instead of 104.5. The author thinks, however, that peptone acts on the fermentation indirectly increasing the activity of the ferments which convert starch into sugar and decompose sugar into alcohol and carbon dioxid.

The experiments in a 1 per cent solution of asparagin gave correspondingly low values for the alcoholic coefficient, 95.1 in the mean.

In 2 series of experiments in solutions of saltpetre, one lasting 7 days and the other 14 days, it was found that in those of shorter duration the yield of alcohol was so high that it was impossible to suppose that any appreciable amount of alcohol was oxidized by the oxygen set free in the process of reduction of the saltpetre by the seed. In the longer experiments the alcohol decreased in amount and nitrogen was set free, corroborating the views of Stoklasa and others.

The experiments referred to were all made with peas (*Pisum sativum*). The intramolecular respiration of castor beans was found to be very weak for all the solutions tested.—P. FIREMAN.

On the nature of the middle lamella, H. Devaux (*Mem. Soc. Sci. Phys. et Nat. Bordeaux, 6. ser., 3* (*1903*), *pp. 89–120*).—After reviewing some of the numerous opinions regarding the constitution of the middle lamella occurring in plants, an account is given of micro-chemical studies of a considerable number of species of plants representing widely separated genera and families. The methods of examination and technique of the specimens are described at length.

The author concludes that from the reactions observed the middle lamella in the softer tissues of plants is not composed of pectate of lime but of pectose, and, contrary to the opinion of many chemists, pectose, at least that occurring in the middle lamella, is readily attacked by either hot or cold, dilute or strong, alcoholic or aqueous acids. In this action an intermediate body between pectin and pectose is formed.

A preliminary note on the action of the radiations from radium bromid on some organisms, H. H. Dixon and J. T. Wigham (*Sci. Proc. Roy. Dublin Soc., n. ser., 10 (1904), II, No. 19, pp. 178-192, pls. 3*).—A report is given of the behavior of seedlings of *Lepidium sativum*, specimens of *Volvox globator*, and a number of bacteria toward radium bromid. Experiments were planned to find out whether the radiations would act as a stimulus to growth curvatures, or if they would exert a directive action on the growth of the motile organism. At the same time abnormal and pathological effects were looked for.

One hundred seeds of *L. sativum* were evenly distributed over a surface of moist quartz sand, and after germination had taken place a glass tube containing 5 mg. of radium bromid was set over the central seed at a distance of 1 cm. from it. At the end of a few days the seedlings had grown up around the tube, but no curvatures were apparent. The seedlings within 1 cm. radius were slightly smaller than the others, but the difference was not very pronounced, nor did the plants appear in any way abnormal. At the end of 10 days the difference in height was more noticeable, and when the radium tube was removed and the seedlings exposed to daylight the central plants remained behind the others in point of growth for several days, during which they were kept under observation.

In a second experiment seeds similarly treated showed, 3 days after germination, a slight retardation of growth. At this time it was noticed that the number of root hairs of the retarded seedlings was considerably inferior to that of the others, but otherwise the retarded individuals seemed healthy.

A third lot of seedlings were tested in which dry seeds were distributed over moist sand and the radium tube supported at a distance of 0.5 cm. from the seed and the germination observed. As before, a slight retardation was noted, but no injury could be discovered.

Experiments conducted with Volvox showed that after 24 hours no special arrangement of the colonies could be observed, and they were neither attracted nor repelled by the radium tube.

In the case of the experiments with the bacteria the organisms were found to be inhibited in their development and in some cases were perhaps killed. To determine whether the organisms were actually killed or merely arrested in their development, inoculations were made from the apparently sterile patches and in almost every case the development showed that the organisms were not killed, but the action was only inhibitory. It is probable that the radiations caused a change in the medium which was responsible for the failure of development of the organisms.

ZOOLOGY.

The economic value of the bobwhite, S. D. Judd (*U. S. Dept. Agr. Yearbook 1903, pp. 193-204, pl. 1*).—Notes are given on the distribution, habits, and economic importance of this bird. The quail is considered as of importance in destroying weed seeds and insects and in furnishing food and sport.

A study was made of 801 stomach contents of quails, collected every month of the year in 21 States, Canada, and the District of Columbia. An examination of the food showed that 14.93 per cent was animal matter and 85.07 vegetable. Seeds form 50.78 per cent of the food for the year. The majority of this seed is from weeds of which 60 species are represented. The author estimates that in the State of Virginia quails destroy 573 tons of weed seeds annually. Grain forms only about $\frac{1}{4}$ of the food, while large numbers of potato beetles, cucumber beetles, chinch bugs, and other injurious insects are eaten.

Brief notes are given on the means of protecting this bird, and a detailed list is presented of the seeds, fruits, insects, etc., eaten by the quail.

Importation of game birds and eggs for propagation, T. S. Palmer and H. Oldys (*U. S. Dept. Agr., Farmers' Bul. 197, pp. 30, fig. 1*).—Since the passage of

the Lacey Act, more than 23,000 birds have been imported into the United States, of which the most important are quail, pheasants, partridges, ducks, and geese. About 2,000 eggs have been imported since the passage of the Egg Act in June, 1902. A brief account is presented of the nature of these importations, with notes on the countries from which birds are imported and on the success of the importations.

Some new facts about the migration of birds, W. W. Cooke (*U. S. Dept. Agr. Yearbook 1903, pp. 371–386, figs. 2*).—A general discussion of the causes of migration, the means by which birds find their way during migratory flights, the distance and routes of migration, casualties during migration, relation of migration to temperature, and variations in the speed of flight. While many casualties may occur during the flight of birds over long stretches of water, observations show that as a rule long flights are made with apparent ease and that the birds do not alight immediately upon reaching the shore.

Causes of the diminution in the number of useful birds, A. Truelle (*Jour. Agr. Prat., n. ser., 7 (1904), No. 23, pp. 742–744*).—A brief discussion is given of the influence of climatic changes, the operations of bird hunters and other agencies upon the number of birds.

Birds in relation to agriculture, Gunning (*Transvaal Agr. Jour., 2 (1904), No. 7, pp. 335–338, pls. 5*).—Notes on the feeding habits and economic relations of various species of herons and storks.

Rabbit destruction (*Jour. Dept. Agr. West. Australia, 9 (1904), No. 5, pp. 392–396*).—Various kinds of poison baits are described, such as phosphorized oats or wheat, apples and strychnin, grain and arsenic, etc. Methods of applying the baits are also described.

Trapping rabbits inside fences, T. Potter (*Jour. Agr. and Ind. South Australia, 7 (1904), No. 11, pp. 621, 622, figs. 2*).—A description is given of a method of using wire fences around enclosures so as to entrap rabbits.

Destruction of rats, G. Gándara (*Com. Parasit. Agr. [Mexico], Circ. 7, pp. 19, figs. 28*).—The direct injuries caused by rats and their agency in transmitting infectious diseases are discussed. The author mentions various natural enemies of rats and artificial means of repression, such as poisons, traps, etc.

Usefulness of the American toad, A. H. Kirkland (*U. S. Dept. Agr., Farmers' Bul. 196, pp. 16*).—This bulletin is essentially a condensed form of the material published in Massachusetts Hatch Station Bulletin No. 46, and previously noted from that source (E. S. R., 9, pp. 330–332).

The economic value of Pennsylvania animals in relation to agriculture, shown in the agricultural exhibit of Pennsylvania at the St. Louis Exposition, H. A. Surface (*Pennsylvania State Dept. Agr., Mo. Bul. Div. Zool., 2 (1904), No. 1, pp. 32, pls. 14*).—A detailed description is given of the Pennsylvania exhibit in economic zoology at the World's Fair.

Results of the Swedish zoological expedition to Egypt and the White Nile, 1901, I, L. A. Jägerskiöld (*Upsal, Sweden: K. W. Appelberg, 1904, pp. 250, pls. 9, figs. 12*).—This report contains articles on White Ants in the Sudan, by I. Trägårdh; *Scaphanocephalus expansus*, by L. A. Jägerskiöld; Water Beetles, by D. Sharp; Lepidoptera, by C. Aurivillius; Ants in Egypt, by G. Mayr; Termitophilous Insects, by E. Wasmann; Birds from the White Nile, by L. A. Jägerskiöld, etc.

Destruction of vermin (*Agr. Jour. Cape Good Hope, 25 (1904), No. 1, pp. 46, 47*).—Notes on fencing, poisoning, and other methods of preventing losses to stock from jackals.

METEOROLOGY—CLIMATOLOGY.

Weather Bureau stations and their duties, J. Kenealy (*U. S. Dept. Agr. Yearbook 1903, pp. 109–120, figs. 2*).—This article briefly reviews the origin and development of the meteorological service, describes the general features of the equipment and organization of Weather Bureau stations, and explains the nature of the daily duties

of observers at these stations. The flags, pennants, and signals used by the Weather Bureau in forecasting the weather and temperature are described and their use explained.

Use of Weather Bureau records in court, H. J. Cox (*U. S. Dept. Agr. Yearbook 1903, pp. 303–312*).—The extent to which Weather Bureau records are used in court and their value as evidence are discussed.

Meteorological observations, J. E. Ostrander, F. F. Henshaw, and G. H. Patch (*Massachusetts Sta. Met. Buls. 184, 185, 186, pp. 4 each*).—Summaries of observations on pressure, temperature, humidity, precipitation, wind, sunshine, cloudiness, and casual phenomena during April, May, and June, 1904. The data are briefly discussed in general notes on the weather of each month.

Precipitation for twenty-nine years at Dodge City, Kans., E. D. Emigh (*Mo. Weather Rev., 32 (1904), No. 3, pp. 115, 116*).—All available data for the period are compiled. These do not show any increase in the rainfall of western Kansas during the period.

Summaries of temperatures, rainfalls, and sunshines, E. F. Ladd (*North Dakota Sta. Rpt. 1903, pp. 16–20*).—Summaries are given of monthly and annual precipitation at Fargo during 1903 and 8 preceding years; on sunshine during 1903 and 4 preceding years; and evaporation from a water surface during May to September, 1903.

The mean temperature during 1903 was 37.7°, the maximum 97° in June, the minimum —38° in February. The total rainfall was 23.81 in., which is 2.93 in. above the average for the past 12 years. The percentage of sunshine was 41.18, having steadily decreased from 48.8 per cent in 1899. "The total amount of water evaporated from a water surface for the 5 months May to September, inclusive, was 41.87 in., or an average of 8.37 in. per month, or a daily average of 0.263 in."

Meteorological conditions in Norway, 1902 (*Aarsber. Offent. Foranstalt. Landbr. Fremme, 1902, pp. 659–679*).—A summary of the average temperature of the air and the precipitation for each month of the year, for the various weather stations of Norway.—F. W. WOLL.

Relation of precipitation to yield of corn, J. W. Smith (*U. S. Dept. Agr. Yearbook 1903, pp. 215–224, charts 8*).—This article is mainly a series of charts showing the close relation which exists between precipitation and yield of corn per acre during a series of years in the region covered by Ohio, Indiana, Illinois, Iowa, Nebraska, Kansas, Missouri, and Kentucky.

A method of avoiding the danger of night frosts by application of frost torches, S. Lemström (*Svenska Mosskulturför. Tidskr., 17 (1903), No. 6, pp. 420–428; trans. from Mitt. Ver. Förd. Moorkultur, 1903, No. 15–16*).

WATER—SOILS.

[Analyses of water], P. Carmody (*Ann. Rpt. Govt. Analyst [Trinidad], 1903–4, pp. 8–10*).—Tabulated analyses are reported of samples of the Port-of-Spain and San Fernando water supplies taken at different dates, of miscellaneous samples of water, and of rain waters, the latter showing monthly averages during 1903 of chlorin, total ammonia, and nitrogen as nitrates.

Methods used for controlling and reclaiming sand dunes, A. S. Hitchcock (*U. S. Dept. Agr., Bureau of Plant Industry Bul. 57, pp. 36, pls. 9, figs. 9*).—This bulletin discusses the formation of sand dunes and methods of fixing the shifting sands, and gives the results of a personal study of the methods of control employed in the Netherlands, Denmark, Germany, and France. The methods now in successful use on a large scale are of three classes:

"(1) Transplanting sand-binding plants upon the dunes, sufficiently thick to form a living cover; (2) covering the entire surface with some inert material which pre-

vents the wind from reaching the sand, and (3) covering the surface with a network of brush fence which, while not preventing the wind from reaching the sand, lessens its velocity and prevents drifting. . . .

"The sand is first held in place by some inert covering or a plantation of grass, and afterwards a forest is established by transplanting young trees.

"Trees will not grow in the immediate vicinity of the ocean; hence a narrow strip along the coast must be permanently held in place by means of a sand-binding grass.

"The best grass for this purpose is beach grass (*Ammophila arenaria*), which grows naturally along the sandy seashores of the North Atlantic coast. The same species grows along the shores of the Great Lakes and on the Atlantic coast of the United States as far south as North Carolina.

"The grass is transplanted in rows or squares in autumn or spring. Satisfactory results can not be produced by sowing the seed of this or of other plants directly upon the unprotected sand.

"Where heather grows in sufficient abundance this is cut and laid upon the surface of the sand.

"The third important method for preventing drifting is the use of sand fences. These consist of rows of rough stakes or pieces of brush driven into the sand and projecting above the surface from 1 to 3 feet. For holding the sand the shorter stakes are placed in squares of 9 to 12 feet, forming a network. For accumulating sand in hollows or repairing breaches in a protecting dune the high fences may be used. Solid fences are not used.

"The drifting of the sand having been prevented by one of the above methods, young trees are set out to form the permanent covering of forest. In northern Europe no satisfactory results have been obtained in establishing a forest by sowing the seed, but in southwestern France a forest was produced by sowing the seed of *Pinus maritima* upon the sand and covering it with brush.

"The trees used are: In the Netherlands, *Pinus austriaca* and *P. laricio* near the coast, *P. sylvestris* on the interior dunes; Denmark, *Pinus montana* near the coast and *Picea excelsa* (preceded by *Pinus montana*) on interior heath land; Germany, *Pinus montana*; France, *Pinus maritima*."

Drift-sand reclamation work, T. R. Sim (*Natal. Agr. Jour. and Min. Rec., 7 (1904), No. 3, pp. 259–264, figs. 3*).—An account is given of the reclamation work being carried on at Durban for the prevention of the drifting of sand along the beach.

Soil studies, E. F. Ladd and H. M'Guigan (*North Dakota Sta. Rpt. 1903, pp. 23–33*).—The results of studies of the composition and properties of humus from different sources are reported, showing "that when fractional precipitation is employed with humus extracts very different results are had with varying conditions of soils. In some cases all of the humus is precipitated in the first fractional, and in other cases all may come down in the last fractional, and in other cases about the same amount will be had for each precipitation. It has been found, however, that these several precipitates have very different values and widely varying compositions. This problem is now being further investigated, and it is believed results can be had which will throw much light upon some of the problems not well understood."

Some results of investigations in soil management, F. H. King (*U. S. Dept. Agr. Yearbook 1903, pp. 159–174*).—This article discusses advantages of thorough cultivation in the South, loss of water by evaporation from southern soils, cultivation to make water-soluble plant food available, faulty methods of cultivation, need of greater porosity and better granulation for soils of South Atlantic and Gulf coastal plains and of more frequent and deeper plowing, importance of the granular structure in soils and the conditions which favor its development and maintenance, need of increasing the organic matter in southern soils, relative rates of nitrification in

some southern soils, and influence of lime and stable manure on nitrification and water-soluble phosphates and sulphates.

Frequent and thorough cultivation to conserve soil moisture and render plant food available is shown to be of great importance, especially in soils of close structure and feeble granulation, such as are found in many parts of the South. Objections to the common practice of running the plow close to the rows of corn and throwing the earth away from the plants are pointed out, and the advantages of flat cultivation for corn, potatoes, and cotton are explained. More frequent and deeper plowing is recommended as a means of improving the mechanical condition of the soils.

Some soil problems for practical farmers, E. C. CHILCOTT (*U. S. Dept. Agr. Yearbook 1903, pp. 441–452*).—The lack of proper instruction in schools and colleges regarding the origin and properties of soils is pointed out, and suggestions are made regarding home study of physical geography and geology by farmers as preliminary preparation for the practical study of soil problems.

The article also discusses the essentials of a progressive farmer, requisites for the successful teacher or investigator, the relation of the scientist to the farmer, and methods and value of crop rotations, the discussion of the last topic being based upon the results of experiments carried on at the South Dakota Station during the last 7 years. "Crop rotation is only one of the many soil problems that should be worked out in the field at the experiment stations and by farmers upon their own farms; and the farmer and the scientist should keep in close touch, so that each may profit by the experience of the other."

"Sour" or acid soils and their treatment, H. G. FOURCADE (*Agr. Jour. Cape Good Hope, 25 (1904), No. 1, pp. 33–43*).—A general discussion of the character of decomposition which organic matter undergoes in the soil, the conditions which affect soil acidity, methods of treatment of acid soils, and crops adapted to such soils. Numerous references to the literature of the subject are given.

The relation of humus to plant growth, V. H. DAVIS (*Jour. Columbus Hort. Soc., 19 (1904), No. 2, pp. 55–60*).—A general discussion of this subject.

Factors of availability of plant food, G. S. FRAPS (*Amer. Chem. Jour., 32 (1904), No. 1, pp. 1–13*).—This is the full text of the paper, an abstract of which has already been noted (E. S. R., 15, p. 858).

FERTILIZERS.

Experiments with nitrogenous fertilizers, H. J. PATTERSON (*Maryland Sta. Bul. 91, pp. 25–53*).—This bulletin discusses the early use of nitrogenous fertilizers, the importance of nitrogen as a plant food, loss of nitrogen from the soil, general conditions indicating the need of nitrogen, quantity of nitrogen annually removed from Maryland farms, the origin and supply of nitrogen in soils, condition of the nitrogen of soils, nitrification, sources of nitrogen, the use of the free nitrogen of the atmosphere by plants, and artificial inoculation, and gives a summary of results of experiments begun in 1897 on medium-stiff clay loam. The object of these was to compare different times of applying nitrate of soda (just before planting with and without lime, at period of most active growth, and one-half before planting and one-half at time of most active growth), to test the comparative effects of nitrate of soda and sulphate of ammonia and of lime applied with mineral sources of nitrogen, to compare nitrate of soda combined with sulphate of potash with nitrate of potash, to compare different sources of organic nitrogen (including dried blood, raw and dissolved leather waste, raw and dissolved hair waste, bone tankage, dried fish, cotton-seed meal, and stable manure), and to test the effect of treating hair and leather waste with acid. The materials were applied in amounts supplying 32 lbs. of nitrogen per acre. The crops for which data are given are corn, wheat, and hay.

The results in general favor the application of nitrate of soda before planting rather

than after the crop is partially grown, and indicate that a top-dressing of this substance pays well as a rule on wheat which for any cause (either poor land or from late seeding) is backward in the spring, although its use is of doubtful benefit on land which is well supplied with plant food. Nitrate of soda gave uniformly and decidedly better results than sulphate of ammonia, both with and without lime. Nitrate of potash gave better results than nitrate of soda combined with a potash salt (sulphate), but the advantage was not great enough "to warrant the difference in cost which usually prevails." The organic sources of nitrogen were not as active as nitrate of soda. Of the three principal forms tested blood stood first as regards effectiveness, leather second, and hair last. The results seem to show decided advantage from treating leather with acid, but little or no advantage from so treating hair. Fish gave better results than bone tankage and stable manure than cotton-seed meal.

Brief accounts are given of miscellaneous experiments with vegetables and in top-dressing grass land and lawns. As a result of 2 years' experiments the conclusion is reached "that either bone or fish tankage is the most desirable material for top-dressing lawns, and for the city or town lawn is much easier to get, cheaper, and more agreeable to use than stable manure."

Experiments on supplying the nitrogen requirements of plants from the atmosphere, Steglich (*Ber. Tät. Landw. Abt., K. Vers. Stat. Pflanzenkult., Dresden, 1903, pp. 2, 3*).—This is a brief report of progress in experiments begun in 1900 to determine whether under systems of fallow or green manuring it is possible to derive sufficient nitrogen from the air to maintain normal yields. The principal data obtained in experiments on loam and sandy soils in vegetation pots are tabulated, but no conclusions are drawn.

On the preservation of liquid manure, J. Sebelien and E. Forfang (*Norsk Landmandsblad, 23 (1904), No. 11, pp. 135, 136*).—In laboratory trials with peat litter, or peat litter and sulphuric acid, as preservatives of liquid manure, 30 gm. of peat or 5 cc. of sulphuric acid per 200 cc. of liquid manure prevented any loss of nitrogen during a period of 1½ months, while a loss of 54 per cent occurred when no preservatives had been added. In another series of trials 25 gm. of peat litter per 300 cc. reduced the loss of nitrogen during 125 days from nearly 60 per cent to 5 per cent, there being practically no loss when peat was added in the proportion of 25 gm. to 100 cc. or to 200 cc. of liquid manure.—F. W. WOLL.

On the fineness of slaked lime, H. von Feilitzen (*Svenska Mosskulturför. Tidskr., 17 (1903), No. 5, pp. 320–322*).—Trials conducted at Flahult experiment station showed that water-slaking is superior to self-slaking in open air, although even the latter method was found to give lime of considerable fineness, viz, from 52 to 75 per cent of "fine-meal" (finer than 0.2 mm.).—F. W. WOLL.

Pot experiments with superphosphate, Thomas slag, bone meal, and phosphorite, A. Rindell (*Landtbr. Styr. Meddel., 1903, No. 44, pp. 19–28*).—The results obtained by the author indicate that superphosphate has a higher value as a phosphoric-acid fertilizer than either Thomas phosphate or bone meal, and that the latter fertilizers have a similar effect; that bone meal, therefore, is a more valuable fertilizer in comparison with Thomas phosphate than is indicated by the results of German experiments.—F. W. WOLL.

Cooperative field experiments with Thomas slag and kainit, A. Rindell (*Landtbr. Styr. Meddel., 1903, No. 44, pp. 1–19*).—This is a compilation of the results of experiments conducted by the author at different Finnish farms. Summary statements of the data obtained are given, with a brief discussion of the results.—F. W. WOLL.

Experiments with commercial fertilizers, E. F. Ladd (*North Dakota Sta. Rpt. 1903, pp. 20–23*).—The results of cooperative experiments with fertilizers on wheat in different parts of the State are briefly reported. In these experiments there was

apparently no marked advantage from the use of fertilizers, although in parallel experiments carried on at the station there was a decided benefit both as regards yield and quality of product from the use of fertilizers.

On calcium cyanamid, H. von Feilitzen (*Svenska Mosskulturför. Tidskr., 18 (1904), No. 1, pp. 54–56*).—A historical sketch of the efforts made to utilize the nitrogen of the air for fertilizing purposes, with description of the new fertilizer, calcium cyanamid.—F. W. WOLL.

Fertilizers, R. E. Rose and E. E. McLin (*Florida Mo. Bul., Dept Agr., 14 (1904), Nos. 1, pp. 25–46; 2, pp. 27–50; 3, pp. 27–46; 4, pp. 27–50*).—These bulletins give the results of fertilizer inspection under State law, with notes on use of fertilizers, formulas for special crops, and miscellaneous information.

Commercial fertilizers (*Quart. Rpt. Kansas State Bd. Agr., 23 (1904), No. 90, pp. 14*).—A brief report is given of work done under provisions of the State law enacted in 1903, the text of which is given, with a discussion of the relation of the Kansas farmer to commercial fertilizers.

Fertilizers, B. W. Kilgore (*Bul. North Carolina State Bd. Agr., 25 (1904), No. 4, pp. 39*).—This includes analyses of fertilizers inspected during the spring of 1904 and of samples of cotton-seed meal, with a list of brands of fertilizers registered in North Carolina for 1904, explanations of terms, notes on valuation, etc.

Law regulating the sale of commercial fertilizers, E. F. Ladd (*North Dakota Sta. Rpt. 1903, pp. 13–15*).—The text of the State law regulating the sale and analysis of fertilizers, approved March 19, 1903, is given. The law applies to all fertilizers the selling price of which exceeds $5 per ton and requires a license fee of $20 for each and every brand of fertilizer carrying a distinctive name, brand, or trade-mark, and a statement on each package showing percentages of phosphoric acid soluble in water, reverted, insoluble, and total; nitrogen in nitrates, as ammonia, and total; potash soluble in water, and chlorin. The sale of leather or its products or other inert nitrogenous material in any form is prohibited without an explicit printed statement regarding the nature of the material. The enforcement of the law is intrusted to the director of the North Dakota Agricultural Experiment Station.

Analyses of commercial fertilizers, M. B. Hardin (*South Carolina Sta. Bul. 87, pp. 18*).—This bulletin reports analyses of 171 samples of fertilizers collected during the season of 1903–4, and briefly discusses the composition and valuation of commercial fertilizers.

Commercial fertilizers, M. B. Hardin (*South Carolina Sta. Bul. 85, pp. 9*).—A summary is given of the results of analyses of 340 samples of commercial fertilizers examined during 1902 and 1903, with a comparison of the results with those of previous years, as well as remarks on cotton-seed meal.

On the economic application of sawdust, G. A. Sellergren (*K. Landt. Akad. Handl. och Tidskr., 42 (1903), No. 4, pp. 301–309*).

Covered drying frames for peat litter, H. V. Tiberg (*Svenska Mosskulturför. Tidskr., 17 (1903), No. 5, pp. 324–328, figs. 3*).

FIELD CROPS.

Annual report of the Alaska Agricultural Experiment Stations for 1903, C. C. Georgeson (*U. S. Dept. Agr., Office of Experiment Stations Rpt. 1903, pp. 313–389, pls. 9*).—In connection with the progress reported for 1903 the organization and previous work of the stations is reviewed, the outlook for the future discussed, and plans for scientific investigation outlined.

Work at Sitka Station.—The vegetables tested were grown on soil cultivated for 3 years and not yet comparable with an average good garden soil. Broad Windsor bean planted May 21 produced a large number of pods ready for use by September 1. Four varieties of beets, Extra Early Egyptian, Golden Tankard, Mammoth Food,

and Eckendorfer, made a rapid growth through the latter part of the season, but on account of the soil being too wet all were small. Improved Half Dwarf Brussels sprouts started in the hot bed April 20 and set out June 6 and 9 showed much variation among individuals, but some plants gave very satisfactory results.

Of seven varieties of cabbage, Early Winningstadt, Early Summer, Extra Early Express, Late Drumhead, and Danish Ball Head, started in the hot bed April 20, produced good heads. Chantenay Half Long carrot and Giant Pascal, Improved White Plume and Golden Self-Blanching celery gave promising results. Dwarf Green Curled Scotch kale gave equally good yields whether sown in the open ground May 21 or started in the hot bed April 20 and set out June 9. Scotch kale is considered one of the reliable garden crops for Alaska. Trondhjemsk kohl-rabi proved adapted to the region and Extra Curled parsley yielded excellent leaves.

All varieties of lettuce seem to do well in Alaska, but no one variety can be recommended for the whole Territory. San Francisco market has so far given the best results of all the varieties tested. Of the varieties of peas grown, Earliest of All, or Alaska, is recommended for general planting. Yakima potatoes planted on old ground May 6 to 8 and dug October 9 to 13 yielded at the rate of nearly 300 bu. per acre. Rhubarb, ruta-bagas, sage, and turnips grew well.

A nursery has been started at the station and notes on the growth of apple, cherry, and plum trees, and raspberries, currants, strawberries, and cranberries are given.

The results with field crops and forage plants are briefly presented. Lapland barley sown May 29 was harvested September 25 and Success sown the same date was harvested September 21. Sisolsk sown on May 23 and Manshury May 28 were harvested September 19 and September 10, respectively. Sixty-Day oats has been found early enough to mature, but it lodges badly. Burt Extra Early which stood next in earliness produces a stronger straw and a heavier grain. Swedish Select oats has given good results for 2 seasons. Improved Ligowo and Nameless Beauty are good varieties for hay and silage. Romanow Spring wheat sown May 7 was harvested September 19. This is the best variety of spring wheat tested at the station. Giant French Winter rye withstood the winter and yielded grain of fair quality. Riga fiber flax sown June 4 was ripe for pulling October 3, but its quality was injured by lodging. Russian buckwheat made a good growth and was harvested September 12.

Among the different grasses tested, Tall Meadow Oat grass is the most promising. Timothy did not seem as valuable as either Tall Meadow Oat grass or orchard grass. In addition to the grasses mentioned, Perennial Rye grass, Red Top, Kentucky blue grass, and Meadow foxtail were tested. None of the grasses suffered from winter killing and all matured seed.

Work at Copper Center Station.—The general conditions of the region are described and the results with field and garden crops briefly noted. Although frost occurred in every month of the year, Manshury, Lapland, Sisolsk, Royal, Trooper, No. 6175, Black Hulless, and No. 9133 barley, and Nameless Beauty, Burt Extra Early, Sixty Day, Finnish Black, No. 2800, and Swedish Select oats matured. Hardy garden vegetables as well as grasses and clover sown in the spring grew well. Spring wheat, emmer, buckwheat, and peas were killed by frost August 27 before they were ripe. Flax sown broadcast May 20 stood 30 inches high August 10 and produced the first ripe seed August 25, but only a small per cent of the seed had ripened by September 10. Good stands were secured with timothy, orchard grass, tall meadow-oat grass, tall meadow fescue, smooth brome grass, and perennial rye grass.

Most of the common, hardy vegetables were tested. Little Gem and Earliest of All peas planted May 14 were ready for table use 88 and 65 days from planting, respectively. Big Boston and Early Curled Silicia lettuce were of excellent quality and made a thrifty growth. Extra Early Red onions did not grow very large, but were fit for table use. Promising results are also recorded for radishes, carrots, turnips, ruta-bagas, parsnips, beets, beans, kale, and cress.

Work at Kenai Station.—The general improvements and conditions at the station and the station work are mentioned and the results of different culture tests are noted. Vegetables in general, with the exception of cabbage, celery, and parsley, did not grow well this season. Early Rose and Early Burbank potatoes were planted May 23 and harvested September 24, and of the yields produced ⅜ and ½, respectively, were marketable. Giant Winter rye was sown August 25, 1902, and harvested September 21, 1903. The straw ripened, but the grain was not matured enough to grow. Excelsior Winter rye gave the same results. Romanow Spring wheat, Manshury barley, Sixty Day, Swedish Select, and common oats, and Orenburg buckwheat did not mature. The straw of the wheat and of Swedish Select oats was harvested for hay.

Of the grasses sown in the spring of 1902, Lolium perenne and Avena elatior were winterkilled. Alopecurus pratensis grew 30 in. high and was mowed for hay July 6 and had produced a second crop, although smaller than the first by September 10. Bromus inermis made a good stand and grew 16 in. high. The following grasses and forage plants sown June 1, 1903, also produced good stands: *Dactylis glomerata*, *Avena elatior*, White clover, Red clover, Alsike clover, *Phleum pratense*, *Lolium perenne*, *Agrostis vulgaris*, and Rape. Hemp was a failure.

Work at Rampart Station.—The following grains again matured this year: Flying Scotchman, Black Finnish, Burt Extra Early and common oats, Manshury barley, and Romanow Spring wheat. The Black Finnish oats stood 5 ft. high and yielded a good grain. Manshury barley was also good, while the grain of the others was inferior.

Cooperative experiments on Wood Island.—Beardless and Manshury barley and flax matured and the results with oats were also quite favorable. A mixture of oats and White Canadian and Blue Prussian peas yielded about 8 tons of green forage per acre. Excelsior, Giant, and Schlanstedt rye grew 5 ft. high, but produced empty heads. Spelt and spring wheat gave some promise of ripening. Timothy sown 2 years ago is reported as being 3 ft. high and having long full heads. A half acre of *Bromus inermis*, sown the year before, produced about half a ton of hay. White clover sown with timothy made a good showing. Of the vegetables tested, lettuce, parsley, potatoes, and radishes have given encouraging results. The growth of flowers and trees is also briefly noted. A milk record of 5 cows for August, 1903, shows a total milk production of 2,649.5 lbs. A total yield of 2,610 eggs was obtained from 26 hens and 9 ducks during 6 months beginning with March.

A series of reports from seed distribution to parties throughout the Territory is presented, and soil temperatures taken at the Sitka, Copper Center, and Kenai stations, together with meteorological observations for 1902 and 1903 at 19 different points, are recorded in tables.

Annual report of the Hawaii Agricultural Experiment Station for 1903, J. G. Smith (*U. S. Dept. Agr., Office of Experiment Stations Rpt. 1903, pp. 391–418, pls. 4*).—This report, after briefly noting the construction of buildings during the year, together with the additions to the station equipment, discusses at greater length the experiments with different crops. The publications of the station are briefly listed, and work at farmers' institutes and in the outlying islands is noted. A report on the funds of the station is also given.

Experiments in corn culture are carried on in the Kula district to determine the effect of deeper plowing and improved methods of cultivation. Land is usually plowed from 1 to 3 in. deep, but the experiment field was plowed from 6 in. to 1 ft. deep and planted with a number of the best varieties of corn from the Middle West and from the New England States. Leaming and Boone County White give indications of being well adapted to the Kula district. Corn planted in deep furrows in plowed land made a better growth than that which had been planted in surface rows.

The quick rot of potatoes was largely reduced by soaking the seed in a 3 per cent

formalin solution from 20 to 30 minutes before planting, and spraying the furrows with this same solution after planting.

Observations on the taro root-rot disease were continued this year (E. S. R., 15, p. 133). The treated plat, which produced taro almost entirely free from disease the year before, was again planted to this crop without further treatment, and the plants obtained appeared healthier than those on untreated plats near by. A variety test with tomatoes was begun, but is as yet incomplete. Many of the varieties produced a rank growth of vine without setting fruit. An analysis of the soil on which the tomatoes were grown showed that it contained 0.58 per cent of potash, 1 per cent of lime, 4.55 per cent of magnesium, 0.75 per cent of phosphoric acid, and 0.38 per cent of nitrogen.

The forage conditions of Hawaii are described and the dairy industry is briefly reviewed. In general the grasses are few on the ranges, being largely confined to Bermuda grass from the coast to an elevation of 4,000 ft., and to hilo grass (*Paspalum conjugatum*) above that altitude. One of the native grasses, *Heteropogon contortus*, once abundant on the leeward coasts to about 1,000 ft. altitude, has been practically destroyed by overstocking. Culture tests with alfalfa have shown that this crop grows well up to an altitude of about 3,000 ft. and that it can be grown without irrigation at the higher elevations where the rainfall is more abundant.

The extent to which Hawaiian cattle are infected with the liver fluke is pointed out. It is reported that 990 cattle out of 3,376 slaughtered for the Honolulu market during the last 6 months of 1902 were infected with liver fluke, and that 247 out of 487 calves examined during that period also showed infection. The life history of the liver fluke is given and the symptoms it produces in infected cattle described. Infection with this internal parasite is much worse in the windward districts and upper mountain pastures than in the drier portions of the islands.

The culture of tobacco, vanilla, sisal, peppers, castor beans, pineapples, cotton, sugar cane, and coffee in the islands is discussed, and lines of experimental work suggested. A successful experiment in curing and fermenting vanilla pods for the production of commercial vanilla was made at the station in 1903, and as the vanilla bean grows well throughout the islands the production of vanilla on an extended scale is considered feasible. Several of the best varieties of cotton have been grown at the station, and individual cotton plants known to be 15 to 20 years old are reported as existing in the islands.

The entomological work done in the islands is reviewed and the necessity for investigations along certain lines pointed out. The principal insect enemies mentioned are the cane borer (*Sphenophorus obscurus*); the leaf hopper (*Perkinsiella saccharicida*), a recent pest in sugar-cane plantations; the so-called "melon fly;" plant lice, threatening the corn crop of the Kula district; cutworms; a scale insect (*Mytilaspis pinnæformis*) on citrus trees; the Japanese "rose" beetle (*Adoretus umbrosis*) and the "Olinda bug" (*Aramigus fulleri*), destructive to fruits and trees; the peach scale (*Diaspis amygdali*); and the "torpedo fly" (*Siphanta acuta*), injurious to the mango. Besides the common mosquito, the Cuban yellow-fever species (*Stegomyia fasciata* and *S. scutellaris*) are reported as occurring in the islands.

Annual report of the Porto Rico Agricultural Experiment Station for 1903, F. D. Gardner (*U. S. Dept. Agr., Office of Experiment Stations Rpt. 1903, pp. 419–468, pls. 6*).—Progress in the improvement and equipment of the station, together with the results of experimental work, is reported. The scope of the investigations is outlined and the rainfall for 1899 to 1903, inclusive, at 4 different points in the island is recorded.

Of different leguminous crops tested at the station, velvet beans have given the best results. Alfalfa, cowpeas, soy beans, and beggar weed have not so far produced a satisfactory growth The sword bean made a good growth, but it grew slower and for a much longer period than the velvet bean.

The results with grasses and forage plants indicated that Bermuda grass is a better lawn grass under the prevailing conditions than gramma grass. Teosinte and Johnson grass gave promise of good growth for forage purposes. Corn was destroyed by bud worms, which feed on the newly formed leaves in the terminal bud. Native flint corn seemed more resistant than yellow dent, while sweet corn failed entirely. Kafir corn, sorghum, and broom corn proved more resistant than corn. Of many kinds of vegetables from northern-grown seed, only cabbages, carrots, cucumbers, lettuce, and radishes were in a measure successful.

Report of the entomologist and botanist, O. W. Barrett (pp. 429–450).—The collections of economic plants which have been assembled by the station are enumerated and briefly noted. A banana plat of about 3 acres was established, and in planting it was observed that the "ñame," or short portion of the stem base with a corm-like rootstock, was preferable for dry soil; that the "tallo," or 3-ft. section of stem with root, gave best results in wet soil; and that the "pichón," or 2 to 3 ft. sucker or offshoot from the stem base, was most convenient for general purposes. Each of these methods after 8 months had produced about the same number of offshoots. Drying the roots in the sun for several days was found to injure the vitality of the plant and considerably retarded its sprouting. The plants growing in a heavy, red, moist clay with apparently little humus have thus far made the best growth. The varieties of Yautia, yams, miscellaneous native and imported crops, bulbs and fiber plants, cassava, rubber, and cacao, which form part of the collection, are listed and briefly discussed. A forest plat of native and introduced species has been established, and a list of the species set out is given. Propagation experiments with native fruits have been begun and the various species tested in this connection are mentioned.

The discussion of the entomological work for the year consists largely of notes on the various insect pests, including cutworms, coffee insects, insect enemies of citrus stock and miscellaneous fruit trees, and a number of other injurious species. At the station the nests of white ants were soaked with kerosene and burned, and this method of eradication was much more effective than arsenic treatment. Notes are also given on plant parasites and fungus diseases.

Report of the coffee specialist, J. W. Van Leenhoff (pp. 450–454).—Coffee plants were transplanted from the seed beds into nursery beds, of which some were treated with nitrate of soda, muriate of potash, lime phosphate, bone meal, stable manure, and Porto Rican bat guano applied alone and in different combinations. On the beds treated with bat guano, or the same mixed with other fertilizers, the plants grew twice as fast as in the other beds. The bat guano, which is obtained from caves in the island, was analyzed by the Bureau of Chemistry of this Department, which reports the following result: Total phosphoric acid, 12.93 per cent; total potash, 0.96 per cent; total nitrogen, 3.32 per cent; ammonia, 4.03 per cent; moisture, 13.86 per cent; loss on ignition, 52.33 per cent.

The plants developed well the following year and are now used in establishing experimental fields by the stump-planting system. Progress is also reported on experimental work in the improvement of an old coffee grove. The total crop of 10 acres before any experiments were made amounted to 3,387 lbs. of coffee ready for market. The cost of harvesting and marketing the crop was $2.11 per 100 lbs. After the harvest the 10 acres were divided into plats; and experiments in green manuring with leguminous crops, distance tests, renovation of the trees by cutting them down to stumps to cause new growth, and different methods of cultivation have been begun. Experiments in progress with new coffee consist in testing Porto Rican coffee and shade trees, and improved varieties of coffee and shade trees. Young plants grown from seed from the Hawaiian Islands and Ceylon have already been set out, and distance experiments have also been started in this connection.

Report on observations in Porto Rico, F. S. Earle (pp. 454–468).—This report treats of the horticultural possibilities of Porto Rico and of observations on plant diseases

and insect enemies in the island. Notes on diseases and insects affecting oranges, coffee, sugar cane, tobacco, cotton, cocoanut, cacao, papaw, beans, and cowpeas are given.

Crop experiments in 1903, A. M. TEN EYCK and V. M. SHOESMITH (*Kansas Sta. Bul. 123, pp. 181–249, pls. 10*).—These experiments were conducted on 360 plats, ranging from 0.1 acre to 5 acres in size and aggregating about 240 acres. Among the spring wheats the macaroni varieties gave the largest yield and heaviest grain. Six-rowed bearded barley gave the best results, the leading varieties—Common, Bonanza, and Mandscheuri—yielding 33.9, 33, and 32 bu. per acre, respectively. Hot weather was not so injurious to barley as it was to oats. Sixty Day oats stood first with a yield of 53.9 bu. per acre, followed by Black Beauty with 52.1 bu., Kherson with 46.7 bu., and Red Texas with 43 bu. per acre. The early varieties gave much the best results. Early sowing is recommended in order that the crop may escape blight caused by hot weather. Emmer produced 1,756 lbs. of grain, which was more than the highest yields of oats or barley obtained in this test. This crop seemed more resistant to drought, diseases, and unfavorable weather conditions than either oats or barley. Flax planted rather late yielded only 6.5 bu. per acre.

Among the millets German ranked first in the yield of hay and seed, the largest yields being 3.6 tons of hay and 25.2 bu. of seed per acre. Siberian millet ranked second. The following varieties of soy beans are mentioned as yielding more than 13 bu. per acre: Yellow, Small Yellow, Ito San, Early Yellow, Green Samarow, and Early Brown, of which the Ito San and the Yellow varieties are the most productive. The Ito San and Early Yellow rank high in earliness. Of 34 varieties of cowpeas grown, New Era gave the largest yield, 11.07 bu. per acre, and several varieties gave an average yield of 2.5 tons of dry fodder per acre. Coleman, Early Amber, Kansas Orange, and Kavanaugh varieties of saccharine sorghums gave good results. Coleman ranked first in production, with a yield of 40.5 bu. of seed and 7.41 tons of stover per acre, while Amber and Kavanaugh ranked first and last, respectively, in maturity. It was found that 50 days after harvesting, sorghum stover in the stack still contained on the average 51.7 per cent of moisture. The results with nonsaccharine sorghums showed that Yellow Milo maize and Large African millet yielded 5.27 tons of stover and 20.6 bu. of grain, and 5.33 tons of stover and 37.3 bu. of grain per acre, respectively, while Red Kafir corn and Black-Hulled White Kafir corn from seed from the same source yielded 4.42 tons of stover and 57.3 bu. of grain, and 4.07 tons of stover and 59.1 bu. of grain per acre, respectively. The Kafir corn stover contained fully as much moisture when stacked as the stover of the saccharine sorghums. Extra Early Japanese broom corn, with Genuine Dwarf as ranking second, appeared superior to other varieties for broom manufacture and also produced the largest yield of seed, 29.9 bu. per acre. A total yield of 5.25 tons of fodder per acre was obtained from pearl millet, but this crop is considered much inferior to the sorghums. Teosinte did not prove equal in value to corn, Kafir corn, or sorghum for forage.

Eighty-one varieties of corn were under test. The yields of standard varieties under the same conditions varied from 31 to 89 bu. per acre. The yields per acre of the leading varieties were as follows: Hildreth, 89.02 bu.; Brazilian Flour, 82.01 bu.; Hammett, 79.04 bu.; Mammoth, 77.12 bu.; Griffing Calico, 76.64 bu.; Klondyke, 75.70 bu.; Cocke Prolific, 75.70 bu., and Bicker Choice, 74.53 bu. Cocke Prolific and Brazilian Flour were grown from southern-grown seed. The native varieties were generally more productive than the imported sorts. The early maturing varieties from northern-grown seed produced the smallest yields, while the best yields of grain and stover were obtained from the medium to late maturing varieties. In addition to determining the yielding capacity, the varieties were scored with reference to the number of ears produced per plat, height of stalks, height of ears on the stalks, leafiness, and length and circumference of the ears. The following varieties scored highest in these points: Forsythe Favorite, 88.4 per cent; Griffing

Calico, 87.7 per cent; Nebraska White Prize, 87.1 per cent; Sander Improved, 85.7 per cent; Funk Ninety Day, 85 per cent. Heavily manured land yielded from 18 to 25 bu. more per acre than adjacent land which had received no manure. Of 29 varieties planted June 16, the following gave the best yields and matured sufficiently to make good corn: Early Mastodon, 54.4 bu.; Pride of the North, 51.95 bu.; Early Cotton King, 50 bu.; Golden Row, 49.2 bu.; Farmers' Reliance, 48.8 bu.; and Reid Yellow Dent, 50.8 bu. It was found that the number of barren stalks on the different plats varied from 0 to 40 per cent.

Experiments were made in the late planting of forage crops to compare the yields and the relative value of the fodder. The crops were sown broadcast June 24 and the best results were obtained with saccharine sorghum, Kafir corn, and corn, the yields being 7.7, 6.12, and 3.93 tons per acre, respectively. Moisture determinations from samples of the fodder taken December 25 showed 39.4 per cent of moisture in the sorghum, 36.2 per cent in the Kafir corn, and 27.01 per cent in the corn. Corn and soy beans and corn and cowpeas sown broadcast were more satisfactory as late pasture crops than either the saccharine or the nonsaccharine sorghums. Soy beans and cowpeas were eaten better by stock when grown in combination with corn than when planted alone.

Corn, corn and cowpeas, Kafir corn, saccharine sorghum, and alfalfa were tested as silage crops, and the data showed that alfalfa can be put into the silo at a less cost than any of the other crops. Saccharine sorghum and Kafir corn gave the largest yields and were handled at a less cost than corn for silage. Corn ranked second in yield of silage and cowpeas third. Experiments in baling alfalfa from the field indicated that this should be done when it is well cured and ready to be stacked. Baled in this way the hay is more likely to retain its leaves than when baled from the stack.

Report on field crops, J. H. SHEPPERD and E. G. SCHOLLANDER (*North Dakota Sta. Rpt. 1903, pp. 59–101*).—A general description of the work of the agricultural department of the college and station in 1903 is given and the results of different experiments are reported at greater length.

Plant breeding is carried on in cooperation with the Bureau of Plant Industry of this Department, and during the year over 50,000 plants of wheat, oats, barley, flax, buckwheat, millet, alfalfa, red clover, corn, potatoes, brome grass, slender wheat grass, and timothy matured in the plant-breeding nursery. The station distributed 35.75 bu. of corn, 68 bu. of wheat, and 300 lbs. of slender wheat grass to 28, 11, and 4 growers, respectively.

Forty-eight varieties of fife, blue stem, and macaroni wheat were grown in 1903. The varieties giving the largest yields in each class were as follows: Selected McKendry Minnesota No. 181 fife, 44.5 bu.; Selected Haynes blue stem, 47.3 bu., and Nicaragua macaroni, 48.8 bu. per acre. The average yield of the best 6 varieties of fife was 43.17 bu., of blue stem 41.49 bu., and of macaroni wheat 46.65 bu. per acre. The tabulated results show that in general the macaroni wheat gave larger yields than either the fife or the blue-stem varieties. Many of the leading varieties of fife and blue stem were bred at the North Dakota and Minnesota experiment stations.

The results of a fertilizer experiment with wheat are shown in the following table:

Fertilizer experiment with wheat in 1903.

Fertilizer.	Grade.	Weight per bushel.	Yield per acre.	Lodged.
		Pounds.	*Bushels.*	*Per cent.*
Acidulated bone	1N	59.75	30.4	10
Amour Grain Grower	1N	59.50	33.2	5
Ammoniated bone and potash	1N	60.25	32.2	20
All soluble	1N	60.00	31.9	8
Nitrate of soda	1N	59.50	33.0	10
Rotted manure	2N	60.00	29.5	10
No fertilizer	1N	60.00	25.7	3

Of 4 varieties of winter rye, a strain selected at the station gave the largest yield, 33.13 bu. per acre. Among 29 varieties of oats, Selected Tartarian, which came from the station plant-breeding nursery, gave the highest yield in 1903, and the highest average yield for the last 2 years, being, respectively, 77.3 and 70.6 bu. per acre. The leading varieties of barley were Success, Manshury Minnesota No. 6, and Highland Chief, yielding 45.3, 44.5, and 42.7 bu. per acre, respectively. The average yields for 1902 and 1903 were in favor of Minnesota No. 100, Manshury Minnesota No. 6, and Common Six-Rowed. A yield of 54.44 bu. of emmer per acre is reported, and a comparison of the yields of different cereals for the last 6 years shows that emmer heads the list in average yield, being followed closely by barley. The results with flax show that the varieties introduced from Argentina, Russia, and Siberia are not equal to the best common strains. The taller growing varieties all gave small yields of seed. A strain selected by the station stood high in fiber production.

Variety and culture tests were made with corn. The results indicated that among the larger growing varieties under test North Dakota No. 100, Golden Dent, Northwestern Dent, Minnesota King, and Acme, and among the flint-growing varieties Will Dakota, Will Gehu, Longfellow, King Philip, Triumph, and Mercer will prove most satisfactory in the State. A comparison of planting corn in hills and drills, in progress for 6 years, resulted in the largest average yields of air-dry fodder from drills 6 in. apart. The stalks reached the greatest length in the 42-in. drills. Hills 22 in. apart produced a much better yield than hills 42 in. distant.

The average yield of ears for 4 years from 9 different distances in the drill, varying from 6 to 36 in., shows a gradual decrease as the distance between the plants in the drill increases. The yield of fodder also diminished, but with less regularity. The thinner plantings produced the largest ears. The results also show that in the average for 4 years 6 stalks per hill gave a higher yield of fodder and of ears than thinner planting. In 1903 the percentage of ripe corn was reduced when more than 2 stalks were grown per hill. The 1, 5, and 6 stalk hills measured 55 in. in height, while the 2 and 3 stalk hills measured 60 in. The diameter of the stalks diminished with the thickness of planting.

For 2 years corn was planted in 6 in. and 42 in. drills on 6 different dates from May 18 to June 22, inclusive. The water content of the corn in the drills 6 in. apart, determined September 16 when frost interfered with the growth, increased gradually with the lateness of the planting. The green fodder from the earliest planting contained 62.4 per cent of water, while that from the planting made June 8 contained 75.5 per cent. The corn grown in drills 42 in. apart reached the greater degree of maturity. The water content on September 16 in samples of green fodder from plantings made June 1, 8, and 15, was 71.5, 76.7, and 75 per cent, respectively. As the corn in the 42-in. drills reached a greater degree of development and maturity, a high moisture content in the later plantings did not affect curing for fodder to the same extent as it did in the corn from the 6-in. drills. The wider planting admits of cutting and curing in the ordinary way, while the 6-in. drills must be mowed and cured in the swath. The average results for 4 years of a cultivation experiment are in favor of shallow cultivation during the entire season.

Turkestan alfalfa failed to pass the winter of 1902, but a second plat sown in the spring of that year was injured but little during the winter. Grimm alfalfa has given better results than Turkestan.

In the trials with red clover the strains obtained from Minnesota, Michigan, and Tennessee produced the best yields of plump and valuable seed. A one-third acre plat seeded with wheat as a nurse crop in 1902 produced at the rate of 3,615 lbs. of hay per acre. The clover on this plat was 20 in. high when harvested June 25. It is concluded from these results that in the Red River Valley clover should be sown with wheat as a nurse crop at the rate of 15 lbs. of seed per acre and a crop of hay harvested before plowing it under.

The Edgeley subexperiment station, O. A. THOMPSON and J. H. SHEPPERD (*North Dakota Sta. Rpt. 1903, pp. 102–119, pls. 2*).—In connection with a general report on the work conducted at the station during the year, the results obtained with grain and forage crops are reported.

The yield of brome grass, impaired by weather conditions, was 300 lbs. of seed and 1.25 tons of hay per acre. Turkestan alfalfa, timothy, and flax were not successful. Corn following corn gave a poor yield, but corn after wheat produced a good crop of fine fodder. Rape sown in 24-in. drills at the rate of 3 lbs. of seed per acre, gave a yield estimated at 10 tons per acre. Millet sown May 29, and killed by a frost September 14, before much of it had headed, yielded about 2.5 tons per acre. There was practically no difference in the yield of wheat on plats plowed 4 and 8 in. deep. The data of grain and forage crops in rotation are tabulated.

Two varieties each of fife and blue-stem wheats were compared with 5 varieties of macaroni wheat. The 2 best yielding macaroni varieties averaged 21 bu. per acre as compared with 18.40 bu. and 15.40 bu. for the fife and blue-stem varieties, respectively. Macaroni wheat has shown itself superior in yielding capacity and in resistance to drought and hot winds. The results with 5 varieties of oats are recorded, and those of a medium growing season gave the largest yield of grain. Swedish Select oats, recently imported from Russia, produced a stiff straw of good height, well filled heads with large plump kernels, and ranked first in weight per bushel.

Four varieties of barley grown for comparison showed no marked differences in yield, but 6-rowed Manshury led in productiveness, length of straw, and healthful growth. Of 5 varieties of millet sown May 29, only Early Fortune ripened its seed. Siberian and German produced the best hay. In the test with corn, Pride of the North, Triumph, and University produced the highest stalks, with Northwestern Dent, Mercer, and Minnesota King ranking next. The early, small growing varieties of corn could not be harvested satisfactorily with a corn binder. Sorghum in a limited trial showed drought-resisting qualities and gave some promise for fodder in that section.

Report of the Insular Bureau of Agriculture for the year ending August 31, 1902 (*Ann. Rpt. Philippine Com. 1903, pt. 2, pp. 639–741, pls. 27*).—In connection with the general report of the Insular Bureau of Agriculture, brief notes on the work at the different experiment stations in the islands are given. In Malate a small plat of teosinte gave 5 cuttings between March 21 and August 10, producing at the rate of 49¾ tons of green forage per acre. A yield of 100 tons of green forage per acre during the entire year is considered possible. The total yield from 2 crops of tobacco grown from Sumatra seed was at the rate of 1,470 lbs. per acre.

Some of the points of general interest in this report, as showing the progress in organizing experimental work in the Philippine Islands, have been previously noted editorially (E. S. R., 15, p. 633).

The industry in oil seeds, C. M. DAUGHERTY (*U. S. Dept. Agr. Yearbook 1903, pp. 411–426*).—The production of cotton seed and flax seed in the United States is discussed and statistics in this connection are given. The quantities of oil-producing seeds and nuts imported and exported by France, Germany, and Belgium, and the total imports minus the total general exports for the United Kingdom and Denmark are shown in tables. The cultivation of oil-yielding seeds in foreign countries is also noted.

One-horse farm, J. S. NEWMAN (*South Carolina Sta. Bul. 84, pp. 9*).—In this popular bulletin the author urges the use of 2 horses rather than 1, together with modern improved implements on the small farms of the Southern States. A rotation including crops giving direct financial returns as well as those grown for forage and soil renovation is suggested.

Pasture, meadow, and forage crops in Nebraska, T. L. LYON and A. S. HITCHCOCK (*U. S. Dept. Agr., Bureau of Plant Industry Bul. 59, pp. 61, pls. 6, figs. 8*).—

This bulletin describes the climate and soil conditions of Nebraska, reproduces the crop statistics of the State for 1899, presents a classification of forage plants, and reports the results of experiments with grasses and other forage plants by the Nebraska Experiment Station in cooperation with this Department.

Several tests with *Bromus inermis* made since 1897 are noted. Disking brome grass sod on April 8 produced no difference in the growth of the grass. The plats, 16½ ft. by 76 ft. in size, receiving 300 lbs. of well-rotted horse manure in the fall and 10 lbs. of nitrate of soda the next spring, yielded at the rate of 5,666 lbs. of hay per acre, as compared with 2,166 lbs. for the check plat. Manured plats produced a good aftermath and withstood drought well. Sowing at the rate of 14 lbs. per acre produced much more seed than the use of larger quantities of seed. No difference was observed between fall and spring sown plats. Other results indicated that, if the soil is in proper condition, brome grass may probably be sown from April to October 1. When sown with blue grass it was gradually crowded out, but in grass mixtures for pasture it usually showed some advantage over the other species. The results of cooperative experiments with farmers were in general satisfactory.

The tests with different varieties of alfalfa showed that Turkestan alfalfa is well adapted to Nebraska conditions and that in dry seasons it yields better than the ordinary alfalfa. Peruvian alfalfa, after producing a good stand and vigorous growth, was winterkilled. Samarkand alfalfa grew well, produced a thick stand, and proved to be drought resisting, but it was not so tall as the common or Turkestan varieties. A test of seed from different States showed that alfalfa seed should not be brought from a southern to a more northern region or from an irrigated to a nonirrigated soil.

There was no advantage in planting alfalfa in rows and cultivating it.

The use of gypsum, lime cake, and hog manure produced no marked beneficial effect. Light and heavy seed yielded at the rate of 2,500 lbs. and 3,000 lbs. of hay per acre, respectively. The second year there was a much thinner stand from the light seed. Experiments in sowing alfalfa at different times showed that on soil in good tilth and with sufficient moisture the seed may be sown at any time from spring to early fall. The best stand was obtained by sowing without a nurse crop.

On a series of plats alfalfa was sown together with various grasses. In all cases the grass grew well with the exception of timothy, which seemed to be unable to compete with the alfalfa. In a mixture comprising a number of grasses and alfalfa, orchard grass has in 3 years increased to about ⅓ of the number of plants on the plat. Brome grass grew more vigorously where the alfalfa was thickest, which seemed to indicate that it derived some advantage from the fertilizing effect of the alfalfa. Good stands were obtained on disked and broken and disked sandy prairie.

A 30-acre field was sown in April, 1889, with a mixture of 2 lbs. each of orchard grass, timothy, blue grass, tall oat grass, perennial rye grass, and white clover, 4 lbs. of red clover, and 1 lb. of alsike clover. On 5 acres of the tract, 3 lbs. of alfalfa were added. Good yields of hay and excellent pasturage were obtained in 1900 and 1901. In the spring of 1900, the field was disked and sown with brome grass and meadow fescue, which 2 grasses at present practically occupy all the ground, the alfalfa having disappeared. A tract of 30 acres of native pasture sown with blue grass and white clover in 1887 is at present mostly blue grass. As in the foregoing experiment, alfalfa sown on part of this tract was crowded out by brome grass and meadow fescue. On another field sown with brome grass, timothy, orchard grass, blue grass, and meadow fescue, brome grass gained the ascendency.

Yields of hay from meadow fescue at the rate of 2,400 lbs. per acre on one plat and of 2,836 lbs. on another are recorded. This grass did not start so early in the spring as brome grass. Trials of meadow fescue mixed with either timothy, clover, or alfalfa were all successful. Mammoth red clover proved of more vigorous growth and longer lived than ordinary red clover, but in the winter of 1902–3 it was about half winterkilled. It withstood drought better than any other clover. Alsike

clover also stood drought well and gave good results on moist ground. The results obtained with redtop, side oats grama, and wheat grasses are briefly described, and notes on the work with less important grasses and leguminous forage crops are given.

Annual forage crops, including sorghum, millet, cowpeas, small grains, corn, soy bean, rape, Canada field pea, and vetch are discussed with reference to their value for Nebraska, and the yields obtained in culture tests with some of these crops are given. A list of plants which have been tested but can not be recommended concludes the bulletin.

Pasture, meadow, and forage crops, T. L. Lyon and A. S. Hitchcock (*Nebraska Sta. Bul. 84, pp. 66, figs. 5*).—An account of the cooperative work noted above from another source (E. S. R., 16, p. 148).

A six-year rotation of crops, H. J. Wheeler and G. E. Adams (*Rhode Island Sta. Bul. 90, pp. 81–118, pl. 1*).—The results obtained with 3 and 4 year rotations have been previously noted (E. S. R., 12, p. 1030). The experiments here discussed were conducted on 6 plats of poor grass land. The succession of crops for the rotation was as follows: Corn on grass sod, potatoes, winter rye, common red clover with timothy and redtop, grass, grass. A detailed account of the treatment of each of the plats for the term of the rotation is given. The purpose of the experiment was to ascertain if by the use of small quantities of stable manure, supplemented by commercial fertilizers, or if by the use of commercial fertilizers alone this exhausted soil could be improved and finally its fertility be maintained at a profit.

It was found early in the experiment that the influence of wood ashes could be profitably duplicated by the use of lime aud potash salts. One of the plats in the absence of lime and wood ashes showed only a trace of timothy and only 4.8 per cent of red clover, while on another plat which received wood ashes timothy constituted 22.4 per cent and red clover 37.9 per cent of the herbage. A comparison of the yields during the 2 rotations is given in the following table:

Comparison of yields in the first and second course of the rotation.

	Corn.			Potatoes.		Rye.			Hay.	
	Year.	Yield of grain per acre.	Yield of stover per acre.	Year.	Yield per acre.	Year.	Yield of grain per acre.	Yield of straw per acre.	Year.	Yield per acre.

Plat No. 4	......	....	....	1899	183.33	1900	18.93	1.72	1903	4.11

The crops of hay recorded in the table represent the first and last full crops thus far grown in the 2 rotations. The high yield of hay on plat 2 in 1896 is considered to be due to an application of 1,068 lbs. of air-slaked lime per acre in 1894. The top dressing first employed for grass land in these experiments consisted of 120 lbs. of muriate of potash, 120 lbs. of nitrate of soda, and 300 lbs. of dissolved boneblack or its equivalent of acid phosphate per acre; but beginning with 1901 it was changed to 350 lbs. of nitrate of soda, 200 lbs. of muriate of potash, and 500 lbs. of acid phosphate per acre. During the second course of the rotation the potato formula was changed to 200 lbs. of nitrate of soda, 275 lbs. of high-grade dried blood, 800 lbs. of

low-grade acid phosphate, and 300 lbs. of muriate of potash per acre, which was applied entirely in the drill.

The general results of the experiments showed that rye and grass, especially on fine and compact soils, should come early in the rotation and be followed by corn and potatoes after the tilth of the soil has been materially improved. It is believed that, if lime or wood ashes had been applied at the very beginning of the tests, regardless of the crop, the results would have been more satisfactory. The authors believe that, if the rotation is begun as suggested and the fertilizers used during the second course are applied as described, most Rhode Island soils may be profitably renovated and their fertility maintained solely by the use of commercial fertilizers. The financial results obtained on the different plats are shown in tables.

The department of agronomy, L. A. MERRILL (*Utah Sta. Rpt. 1902, pp. XIX–XXXIII*).—The work and equipment of the department are briefly noted and experimental results are recorded. A rotation experiment has been in progress for only 2 years, but some differences as a result of the treatment are already noticed. Two plats upon which wheat is to be grown continuously, the one receiving barnyard manure each year and the other receiving no fertilizer whatever, yielded in 1901, 20.66 and 17.83 bu., and in 1902, 30 and 10.83 bu., respectively. In all cases the yields for 1902 were much greater from the manured than from the unmanured plats, the increase for wheat being 24 per cent in one rotation, 177 per cent in another, and 99 per cent in a third. The results further show the need of fertilization for the successful production of sugar beets. Comparing the results from the barnyard manure plat with those from the plat receiving 200 lbs. of nitrate of soda per acre, it is seen that in both years the yields were in favor of the manure. Summer fallow every third year to follow wheat and oats does not show as large an increase as the continuous cropping with the yearly use of barnyard manure.

Forty-eight varieties of fall wheat were tested, Turkey leading with a yield of 42.17 bu. per acre, and being followed in productiveness by Red Chaff, Siberian, and Ruby. Canadian Wonder, Red Cross, and Ramsey, standing last in the list, yielded each 31.95 bu. per acre. The average yield for the 2 years of the 2 subsoil plats was 9.5 per cent better than that on plats plowed 10 in. deep but not subsoiled.

Thirty varieties of spring wheat were grown, and the highest yield obtained per acre was 44.78 bu. Sixty-Day oats yielded in 1901, 87.18 bu. as compared with 68.75 bu. for the variety next highest in yield; and in 1902 the yield was 88.89 bu., again considerably higher than that of any other variety.

The following varieties of barley, named in the order of highest yield, were grown: Salzer California Prolific, Highland Chief, Mandscheuri, Silver King, Success, California, and Black Barley.

Twelve varieties of macaroni wheat were grown without irrigation, giving an average yield of 32.11 bu. per acre. The leading variety, Mahmoudi, produced a yield per acre of 42.46 bu.

Several varieties of sorghum were tested and the chemical analyses of the cane and the sirup are given. Rape, sand vetch, flat pea, soy bean, giant spurry, cowpeas, velvet beans, teosinte, and lentils have made good growth at the station.

Cross-bending test of stems in cereal breeding, P. HOLDEFLEISS (*Illus. Landw. Ztg., 24 (1904), No. 26, pp. 293, 294, fig. 1; Deut. Landw. Presse, 31 (1904), No. 29, p. 256, fig. 1*).—The value in cereal breeding of cross-bending tests of the straw to determine its strength, with a view to selecting seed from plants with strong stems and consequently with a reduced tendency to lodge, is discussed and methods of conducting the tests together with the apparatus used are described.

The cultivation of corn, C. P. HARTLEY (*U. S. Dept. Agr. Yearbook 1903, pp. 175–192, pls. 5, figs. 7*).—In the discussion of the subject the author considers the production of corn in its relation to the fertility of the soil, means of preventing soil

washing, the retention of soil moisture, fertilizers and crop rotation, and the different phases of the culture of the crop, such as plowing, planting, and cultivation.

Selection of corn and wheat, E. F. Ladd (*North Dakota Sta. Rpt. 1903, pp. 36–41*).—The results with 8 samples of wheat under test since 1900 for the purpose of determining whether the protein content in wheat can be increased by selection, and whether wheats retain this property from year to year, are given in a table. The samples did not all continue to increase their protein content, and in some of them it was even lower in 1903 than in 1900. In 1901, a season unfavorable to full maturity, the protein content was exceptionally high for all samples. A study of the gluten content and of the gluten constituents is reported in progress.

Analyses of corn planted at different distances; of samples selected for high protein content; of the stalks, cob, and kernel of individual plants, and of corn planted on different dates are reported. In all cases, except in the study of individual plants, the results are compared with those of previous years.

Consumption of cotton in the cotton States, J. L. Watkins (*U. S. Dept. Agr. Yearbook 1903, pp. 463–478, pls. 3, fig. 1*).—The history of cotton manufacture in the United States is reviewed by periods, and the consumption and production of cotton and the number of mills and spindles in operation in South Carolina, North Carolina, Georgia, Alabama, Tennessee, and Virginia in different years, from 1850 to 1903, are presented in tables. In addition, the cotton consumed with the number of mills and spindles in operation in Mississippi, Louisiana, Texas, Arkansas, Kentucky, and Missouri at the close of each decade from 1860 to 1900, inclusive, and in 1902 and 1903 are given, and the condition of the cotton industry in various countries during the past 20 years is briefly noted. A tabulated summary of the statistics presented, showing the consumption and production of cotton in the Southern States from 1850 to 1903, concludes the article.

The growing of long-staple upland cottons, H. J. Webber (*U. S. Dept. Agr. Yearbook 1903, pp. 121–136, pls. 5*).—This paper discusses the importance of extending the culture of long-staple upland cottons, notes the history of their introduction, and describes briefly the principal races which are now being grown. Directions for the improvement of varieties, selection of seed, cultivation, picking, ginning, baling, and marketing are also given.

The A, B, C of cotton planting, D. Morris (*Imp. Dept. Agr. West. Indies, Pamphlet 31, 1904, pp. 60*).—The principal facts of cotton culture are presented in a series of questions and answers.

Principal commercial plant fibers, L. H. Dewey (*U. S. Dept. Agr. Yearbook 1903, pp. 387–398, pls. 5*).—After reviewing the importance of the fiber industry and outlining a classification of fibers into cottons and hard and soft fibers, the author presents discussions of American upland, Sea Island, Egyptian, India, and Peruvian cotton, flax, hemp, jute, Manila fiber, sisal, New Zealand hemp, Mauritius hemp, and istle.

Lupines as green manure for rye, Causemann (*Deut. Landw. Presse, 31 (1904), No. 39, pp. 344, 345*).—Rye was sown on light soil after lupines had been turned under by shallow plowing. The seeding was late, October 15, but the crop wintered well and made a rapid growth the following spring.

The percentage of husk in different varieties of oats, C. Hauter (*Illus. Landw. Ztg., 24 (1904), No. 25, pp. 279, 280*).—The percentage of husk determined in 32 varieties is reported, together with the weight of the oats per hectoliter and the weight of 100 whole and husked grains. The grains with the husks removed constituted from about 70 to 75 per cent of the whole grain. Potato and a variety of side oats stood highest in the percentage of husked grains.

Irish potatoes, E. C. Green (*Texas Sta. Bul. 71, pp. 16, figs. 4*).—This bulletin discusses the results of experiments at Troupe Substation. The results of a culture test show that planting 3 in. deep produced a larger total yield and a larger per-

centage of marketable tubers than planting $4\frac{1}{2}$ or 6 in. deep. Shallow planting also produced earlier maturity. Level cultivation proved more profitable than throwing soil to the row and hilling the plants. A second crop of Triumph from home-grown seed ripened a week later than the same variety grown from northern seed. Home-grown and northern-grown seed of Triumph planted March 26, yielded 36 and 24 bu. per acre, respectively. Thorburn, Irish Cobbler, and Eureka, yielding 68, 67, and 53 bu. per acre, respectively, were the most productive among the varieties tested on plats which received no fertilizer.

In connection with fertilizer experiments it was observed that the gray, sandy clay soil with red subsoil at the station responded more profitably to acid phosphates than to any other single fertilizer. In complete fertilizer applications over 6 per cent of potash was unprofitable, while from 8 to 10 per cent of phosphoric acid largely increased the yield. Cotton-seed meal applied shortly before planting did not become available in time to be of benefit to early potatoes.

Competitive potato culture in Belgium in 1903, L. LACROIX (*Jour. Soc. Cent. Agr. Belg., 51 (1904), No. 5, pp. 185–187*).—The variety grown was President Kruger, and the areas devoted to the test varied from 1 to more than 25 ares. The maximum yields per hectare were as follows: Plats containing more than 25 ares, 59,500 kg.; plats from 10 to 25 ares in size, 65,150 kg.; plats from 5 to 10 ares, 64,532 kg.; and plats containing 1 to 5 ares, 44,422 kg.

The effect of frequent cultivation on the yield of potatoes, BACHMANN (*Deut. Landw. Presse, 31 (1904), No. 19, p. 162*).—Potatoes grown on a poor, sandy soil were given different fertilizer applications and some plats were hoed once and others 3 times. Frequent cultivation in all cases gave the highest yields, the greatest increase being obtained on the plats receiving a complete fertilizer. Where nitrogen was not given in the fertilizer the increase was smallest, while the absence of phosphoric acid did not show such marked effects on the yield.

Variety tests with potatoes at Capelle, F. DESPREZ (*Semaine Agr., 24 (1904), No. 1192, pp. 93, 94*).—The tests comprised varieties for industrial and feeding purposes and for general consumption. The leading varieties in the different groups were as follows: For industrial and feeding purposes, Géante blanche, G. bleue, Professor Withmann; for industrial purposes and general consumption, Jaune ronde, Professor Maercker, Fleur de pêcher; table varieties, Georges Poulet, Magnum bonum, Preciosa, Blanche française; and as an especially fine table variety, Marjolin hâtive.

Rice, W. C. STUBBS, W. R. DODSON, and C. A. BROWNE, Jr. (*Louisiana Stas. Bul. 77, 2. ser., pp. 363–393, pls. 18*).—This bulletin is a revision of Bulletin 61 of the station (E. S. R., 12, p. 741), including additional information gained since it was issued. Statistics on the production and importation of rice are shown, the lands suitable for rice culture in Louisiana are described, and general directions for the culture of the crop are given. The analyses of water from different localities used in irrigating rice are recorded in a table, and the fertilizing elements contained in these waters per acre irrigated are estimated.

Green and yellow grained rye and their yields under field conditions, REICHERT (*Illus. Landw. Ztg., 24 (1904), No. 20, pp. 217–219, figs. 7*).—Different experiments with the 2 kinds of rye are reviewed, and attention is called to the fact that on heavy as well as light soils the yields were in favor of the green-grained varieties.

In all tests but one the protein content of the green-grained rye was larger than in the yellow-grained strains. In the one experiment the green rye contained 12.7 per cent of protein and the yellow 14.4 per cent, but the total amount of protein produced per morgen was 265.17 lbs. and 167.04 lbs., respectively. Average results show that the green-grained varieties contained about 4 per cent more protein than commonly grown varieties of rye.

Relation of sugar beets to general farming, C. O. TOWNSEND (*U. S. Dept. Agr. Yearbook 1903, pp. 399–410, pls. 3*).—This article, in addition to pointing out the

relation of sugar-beet culture to general farming, gives directions for the culture of sugar beets and discusses the cost of production and the future of the industry.

Comparative production of alcohol and sugar from the beet (*Jour. Soc. Cent. Agr. Belg., 51 (1904), No. 7, pp. 265, 266*).—Figures are given showing that when alcohol brings 35 francs per hectoliter and sugar 26 francs per kg., distillery beets may be used as well for the production of one as for the other.

Comparative results of seedling sugar canes D. 74 and D. 95 with our home sugar canes (Louisiana Striped and Louisiana Purple), W. C. STUBBS and R. E. BLOUIN (*Louisiana Stas. Bul. 78, 2. ser., pp. 46*).—The history of the 2 seedling canes is given. The analyses of the different canes for the years 1894 to 1903, inclusive, are reported, and the character of the seasons and the results are briefly noted. It is shown that in every instance the 2 seedling varieties were lower in glucose content than the home canes.

A low glucose content is of great advantage in working the juice. D. 74 gave especially favorable results in this respect. The average analysis also showed that this seedling contained 1.8 per cent more sucrose, and D. 95 0.9 per cent more than the home canes. D. 74 yielded 5.68 tons of cane more per acre than the 2 native varieties, while D. 95 was about equal to them in cane production. The financial results presented are based on a value of 4 cts. per pound for yellow clarified sugar, giving half to the producer of the cane and half to the manufacturer of the sugar. On this basis the crop of plant cane and first year's stubble of D. 74 gave an average increase of $39.70 per acre and D. 95 of $21.81 over the home canes; and when the plant crop and the first, second, and third years' stubble were considered, the corresponding figures were $26.28 and $28.14 per acre, respectively.

The results obtained in the sugar house indicated a marked superiority of D. 74 over the 3 other canes, although D. 95 gave better returns than the 2 native sorts. In total extraction D. 74 showed an increase of 7.87 per cent, or nearly 11 per cent in the juice over home canes. A summary of the results gives an increase of 2.34 per cent in extraction, and of 40.7 lbs. of sugar per ton of cane ground in favor of the 2 seedling canes. Cooperative tests made by 27 planters throughout the State confirmed the results obtained by the station. "D. 74 is more vigorous, a more rapid grower, gives a larger tonnage, is an erect cane, and believed from this to be more economical in harvesting, stubbles well if not better than home canes, gives a larger extraction, and has a larger sugar content, yielding more sugar per ton and giving a greater tonnage per acre than home canes. The same remarks in a lesser degree apply to D. 95."

Tobacco culture in South Carolina, T. B. YOUNG (*South Carolina Sta. Bul. 86, pp. 21, figs. 4*).—After briefly reviewing the history of tobacco culture in South Carolina and giving statistical data showing the increase in the tobacco production of the State for a series of years, this bulletin describes the culture, harvesting, and curing of the crop, and presents preventative and remedial measures against the insect enemies and diseases of the plant.

Macaroni wheat, J. H. SHEPARD (*U. S. Dept. Agr. Yearbook 1903, pp. 329–336*).—A discussion is given of the introduction, increase in production, and methods of cultivation of macaroni wheat, and the results of a study of the chemistry and milling factors of this class of wheat, which have been previously noted (E. S. R., 15, p. 1073). The different uses of macaroni wheat are briefly noted.

HORTICULTURE.

Second report on the pithiness of celery, C. F. AUSTIN and T. H. WHITE (*Maryland Sta. Bul. 93, pp. 95–101*).—Further work at the station in the comparison of American-grown and French-grown celery seed as regards the production of pithy and green stalks confirms the results reported in Bulletin 83 of the station (E. S. R.,

14, p. 250), to the effect that French-grown seed produces plants true to type, while American seed produces plants many of which are pithy and green. This result is believed to be due to the more thorough "rogueing" practiced by French seedsmen. In the station experiments seed was raised from a typical stalk of the Golden Self-Blanching variety that was completely pithy. Of 12 plants grown from this seed every one was pithy, and 11 of the 12 developed into large, coarse-growing green plants having no resemblance whatever to the type of Golden Self-Blanching.

"During the same year seed was saved from a solid stalk and from a pithy stalk of Dwarf Golden Heart. From the seed of the solid stalk 14 plants were started and 12 harvested. The 12 plants were true to the type and free from pithiness. From the pithy stalk, 20 plants were raised and every one pithy. They showed as decided reversion of type as the plants from the pithy seed of the Golden Self Blanching variety. Many of the plants from the pithy seed showed the fine parsley-like foliage so common in the wild species.

"After giving this matter careful study there seems to be no doubt but that pithiness in celery is due to the parent plant, and not to any extent to the soil, methods of culture, etc. We believe that the foregoing results fully prove the inference made in Bulletin 83, that pithiness in American celery is due to a lack of 'rogueing' or removing of the pithy plants from the seed beds of American celery seed growers. We also believe that green plants that are not true to the type are caused by the same oversight, namely, by not removing from the seed beds every plant that does not conform to the type of Golden Self-Blanching celery. From a very small amount of work with several other varieties of celery, we are convinced that what is true of the Golden Self-Blanching is true of them.

"The cause of pithiness is hereditary and dates back to the seed-producing plant. The difference in soil, cultivation, season, methods of handling, etc., has very little to do with causing pithiness. The seed is contaminated before it reaches the grower, by a condition that he can not help."

A table is given showing the relative amount of pithy and green celery produced by seed from 29 different seed firms. In some cases as much as 30 per cent of the plants grown were pithy. It is believed that much of the so-called French seed obtained from American sources is adulterated with American seed, and directions are given for detecting such adulterations. The authors believe that "just as good seed can be grown in this country as in Europe, if our growers will give the same care and attention to it. In our work it has been the rarest case to find a pithy or green stalk in celery seed that is imported direct from the best growers in Europe. We believe that such a record can be established by our American growers, if they will 'rogue' their plants, by removing all plants that are pithy and that do not conform to the type of the variety wanted."

Ovidius, a new winter vegetable, G. T. GRIGNAN (*Rev. Hort.* [*Paris*], *76* (*1904*), *No. 8, pp. 177–179, figs. 2*).—Under the name of "Ovidius" the plant *Crambe tataria* has this year been introduced to French commerce. One of the peculiarities which it is claimed must be observed in the culture of this plant is that the seeds must not be covered. If covered with soil they fail to germinate. Germination at best appears to be very slow and irregular. In the fall the young plants are covered over with earth about 2 meters deep, through which the blanched stalks push their way the following March or April. One of the advantages of the plant is that it comes early in the season before asparagus. The decapitated plants form new shoots which serve for production the following year. Directions are given for preparing the plant for the table.

The seeds of garden beans, DENAIFFE (*Jardin*, *18* (*1904*), *No. 412, pp. 116–118, figs. 4*).—French varieties of garden beans are classified and illustrations given of the seeds of about 60 varieties.

Cross fertilization (*Jardin, 18 (1904), No. 412, p. 114*).—It is stated that in some experiments recently reported by M. Leclerc, melons were cross-pollinated with the pollen from melons and from cucumbers. In the latter case there was a marked diminution in the sugar content of the melons, held to be due to the effect of cross-pollinating with cucumber pollen. Melons pollinated with pumpkin and vegetable marrow pollen were also similarly affected. It is pointed out, therefore, that melons should not be planted near these vegetables.

Department of horticulture, C. B. WALDRON (*North Dakota Sta. Rpt. 1903, pp. 120–123*).—Brief notes are given on the culture of plums, apples, strawberries, currants, gooseberries, raspberries, and asparagus at the station. Asparagus rust was very destructive in 1902. Covering the beds heavily with straw in August of that year apparently checked the development of the rust in 1903. It is noted that 2 new varieties showed no sign of rusting during the first season grown.

Experiment station work with apples, C. B. SMITH (*U. S. Dept. Agr., Office of Experiment Stations Rpt. 1903, pp. 537–570*).—A summary is here given of the cultural experimental work reported by the experiment stations in the United States since 1888 with apples. Foreign experimental work along the same lines, so far as available, has been included.

The summary covers the work done on period of growth of the tree; the characteristics of apple buds and pollen; self-sterility in apples; crossing; root-grafting; planting and pruning trees; root-pruning; hardy stocks; orchard cultivation and cover crops; fertilizing orchards; girdling to produce fruitfulness; thinning the fruit; harvesting and storing apples; cold storage; composition of fruit, trees, nursery stock, etc.; and the utilization of waste apples for evaporation, jelly, cider, vinegar, marmalade, etc. The article has also appeared as a separate.

Notes on apple culture, C. F. AUSTIN (*Maryland Sta. Bul. 92, pp. 55–94, figs. 34*).—The author in this bulletin calls the attention of Maryland orchardists to some of the principles and methods that are considered absolutely essential to successful apple growing. Very complete directions are given for the care and management of orchards, including budding, grafting, and pruning.

Relation of cold storage to commercial apple culture, G. H. POWELL (*U. S. Dept. Agr. Yearbook 1903, pp. 225–238, pls. 6*).—The author discusses the present status of the apple industry as regards markets, marketing, cold-storage development, and the proper harvesting and handling of apples to secure the best results in cold storage. The essential points in the article have been brought out in an earlier publication of the Department (E. S. R., 15, p. 581).

An apple for the Tropics (*Gard. Chron., 3. ser., 35 (1904), No. 905, p. 280*).—It is stated that M. d'André has found a new species of Pyrus at the summit of Lang-Bian, at Annam at an altitude of 2,000 meters. The tree is without spines. The flowers have not yet been seen, but the fruit is 4 to 5 cm. across, greenish yellow, and of a rough flavor like that of a crab apple. The climate of Lang-Bian is similar to that of southern Europe. "The importance of the discovery of this new Pyrus rests in the circumstance that it may be used as a stock whereupon European varieties may be grafted," and grown in tropical and subtropical countries.

The lemon industry of Sicily (*West Indian Bul., 5 (1904), No. 1, pp. 63–75*).—Considerable information, obtained largely through the English consul at Palermo and from diplomatic and consular reports, is here given on the citrus industry of Sicily. Cultural methods and the prevailing custom of packing, shipping, gathering, etc., are noted. Some notes on the pickling of lemon and orange peel, and the manufacture of essence are included.

Promising new fruits, W. A. TAYLOR (*U. S. Dept. Agr. Yearbook 1903, pp. 267–278, pls. 7*).—Descriptions, with colored illustrations of the fruit, are given for the Akin apple, a variety well adapted to the fancy fruit trade in the larger cities; the Terry apple, a variety considered very promising for the South; the Hiley peach, a

commercial sort of good shipping quality and excellent flavor, originated in Georgia; the Welch peach, a promising hardy sort obtained in a collection of Hill Chili seedlings; the 2 varieties of prunes, Splendor and Sugar, originated by Luther Burbank; the Headlight grape, originated by T. V. Munson, and especially promising in the South on account of its vigorous growth, disease-resistant foliage, productiveness, and early ripening; and the Cardinal strawberry, a promising commercial sort originated in Ohio.

A new method of budding (*Queensland Agr. Jour., 15 (1904), No. 1, pp. 476, 477, fig. 1*).—In the method described a piece of bone was sharpened like a lead pencil and fitted with a handle. This was used to make incisions into the bark of a 10-year-old peach tree, into which buds were fitted. The buds were held in place by tacking on a small piece of leather, using upholsterers' half-inch gimp pins "which being enameled do not rust." As the buds swelled the tacks were loosened.

The method is recommended for all old trees requiring new wood, "an advantage being that it does not interfere with the tree bearing fruit while the buds are being matured. No string or clay or grafting wax is required, as with the old system." The method is illustrated.

Sexual hybridization and variation by grafting, A. JURIE (*Rev. Vit., 21 (1904), No. 543, pp. 519–523, figs. 2*).—Further evidence is presented to show that hybridization of grapes by grafting can actually take place. Photographs of the changes in grape seeds brought about by grafting are given.

Studies on the manuring of Chablis grapes, E. ROUSSEAUX and G. CHAPPAZ (*Prog. Agr. et Vit. (Ed. L'Est), 25 (1904), Nos. 15, pp. 460–467; 16, pp. 477–487*).—An account of investigations made to determine the fertilizer requirements of the vineyards of Chablis. Analyses with reference to fertilizer constituents are given for the dry leaves and branches and of the marc, wine, and lees obtained from typical vines grown in the vineyards of Chablis. A study was also made of the geology and of the physical and chemical composition of the soil and subsoil in a large number of vineyards throughout the region.

With these data and data from other sources on the effect of different fertilizers on the production and quality of wine, methods of manuring Chablis vineyards are worked out. It was found that typical vines of the district withdraw yearly from the soil the following amounts of fertilizing constituents: Nitrogen, 32 kg. per hectare; phosphoric acid, 6 kg. per hectare; and potash, 27 kg. per hectare. The soils of Chablis were generally found strongly calcareous, rich in potash, fairly rich in phosphoric acid, but a little below normal in nitrogen. They contained only a small amount of gravel, the larger part being made up of fine sand and clay. They would be classed as heavy soils, but owing to the large amount of lime they contained were very permeable and easily worked.

Allowing, therefore, for certain losses which occur in applying fertilizers and for the fact that the vine roots do not reach all the fertilizers applied, and taking into consideration the effect of the fertilizers on the quality of the wine, the authors recommend the use of about 50 kg. of nitrogen per hectare in the vineyards of Chablis and 50 kg. of phosphoric acid. The use of additional amounts of potash with these soils appears to be without effect and is not recommended.

In order that the maximum effect of the commercial fertilizers used may be obtained, an occasional manuring of the vineyards with barnyard manure is recommended. Specifically it is recommended that every third year the vineyards of Chablis be manured with 10,000 to 12,000 kg. of barnyard manure supplemented with 250 kg. of superphosphate. In each of the two intervening years apply 300 kg. of superphosphate and 300 kg. of nitrate of soda per hectare. If farm manure is difficult to obtain, then apply it only every fifth or sixth year, and in the interval use yearly 700 kg. oil cake, 100 kg. nitrate of soda, and 300 kg. superphosphate per hectare.

Grafting European vines on phylloxera-resistant stocks, M. BLUNNO (*Agr. Gaz. New South Wales, 15 (1904), No. 6, pp. 557–572, figs. 18*).—An extensive review of this subject.

Tests of etherization for grapevines, F. CHARMEUX (*Jardin, 18 (1904), No. 416, pp. 188, 189, fig. 1*).—One-year-old grafted grapevines dug in part in the autumn before freezing weather came and kept buried in a cellar, and in part in December after there had been freezing weather, were placed February 3 in 2 jars holding 12 liters each, sealed air-tight, and submitted to the fumes of 3.5 and 4 gm. of ether, respectively, for 48 hours. The roots of the vines were covered with about 4 liters of sand.

The temperature during etherization was kept at 15° C. After etherization the vines were forced in a house held at 20° in the daytime and about 17° at night. Three days later the vines dug before freezing had their buds well swollen and nearly open, while the others had apparently made no growth. At the end of 8 days the early-dug vines were in full vegetation, while on the late-dug vines the buds were just beginning to start. Some control vines that had not been etherized were still in complete repose at this time and did not show signs of growth until about the twelfth day.

It was noticed in the experiment that different varieties and stocks were not all affected alike by etherization, the degree of vegetation being much stronger in some than in others on the same date. In some other experiments Chasselas, Rose, and Gamay-Teinturier-Freau were etherized with 3.5, 4, and 4.5 gm. of ether, respectively. Ten days later the Gamay-Teinturier-Freau, etherized with 3.5 gm., had a good appearance and appeared to be growing where the larger amounts were used. With the Chasselas and Rose, however, the growth with 3.5 gm. was practically nil for a few days and then slowly caught up with the others. When 4 gm. were used all the plants were weaker than the others, while with 4.5 gm. all the plants were completely destroyed.

The effect of etherization on the forcing of plants, G. BELLAIR (*Rev. Hort. [Paris], 76 (1904), No. 14, pp. 333–335*).—This is an abstract of a paper presented by M. Aymard at the Congrès horticole in 1904. According to M. Aymard, success in etherization depends upon the amount of ether employed, the duration of its action, and the temperature during the operation. A study of these factors led to the following deductions:

Anesthetics produce the same effect on vegetation as freezing or drought. Their effects are in proportion to the temperature when used, but inversely proportional to the amount of protection afforded the buds by the bud scales. The amount of liquid used and the duration of action of the vapors are in proportion to this same protection, but inversely proportional to the number of freezings the plants may have received, and proportional to the time between when the operation is performed and the time when the treated plant would vegetate naturally.

Caution must be observed not to treat the plants at too high a temperature. At 25° C., with 35 gm. of ether per hectoliter of air space, the buds were blasted. At 24° the action of ether was also harmful. The best temperature was not determined, but it is believed that it should not exceed 20°. M. Aymard believes that anesthetics act on vegetable tissue as dehydrating agents. As proof of this he found that roots of Lily of the Valley, placed under a bell jar with phosphoric anhydrid and other drying liquids, forced even more quickly than when submitted to ether vapor. It was found also that etherized plants lose considerable in weight.

The anesthetic effect of chloroform is about 4 times as strong as ether, and, therefore, when this agent is used, only about $\frac{1}{4}$ the quantity should be taken. A good combination was found to be 20 gm. of ether and 5 gm. of chloroform per hectoliter of air saturated with vapor. The quantity used should be greatest early in the season and less toward the end of the season. Thus, at the beginning of the season

40 gm. of ether or 14 gm. of chloroform may be used for 72 hours in the case of several varieties of lilacs, while late in the season 25 gm. of ether or 8 gm. of chloroform used 48 hours would be sufficient. Commenting on the above paper, M. Bultel claimed to have secured good results in the etherization of strawberries.

Experiments to determine the effect of ether and chloroform on plants, J. BOLLE (*Ztschr. Landw. Versuchsw. Oesterr., 7 (1904), No. 3, pp. 182, 183, figs. 2*).—An account of experiments made to determine the forcing effect of ether and chloroform on plants, with an announcement of experiments under way to determine the effect of the same agents in forcing grape and rose grafts or cuttings, etc.

Lilacs (*Syringa vulgaris*) subjected to the fumes of chloroform the last of November were in full bloom by Christmas, while control plants otherwise handled in the same manner had made no development whatever. Like results were secured with *Azalea mollis*, Hortensia, and roses which were treated after the leaves had fallen.

The possibilities of the western sand cherry, N. E. HANSEN (*Proc. Soc. Prom. Agr. Sci., 1904, pp. 102–104*).—As a result of fruiting thousands of sand cherries (*Prunus besseyi*) the author is of the opinion that this fruit can be raised to advantage upon the most exposed prairies. Of a hundred selected varieties some have borne fruit ¾ in. in diameter and of good enough quality to eat out of hand. It hybridizes readily with plums and other members of the genus. Seedlings fruit well in 3 years. When worked on native plum stock fruit is obtained in 1 year from the bud or graft; and on heavy soils heavier yields are obtained than on own roots.

The "Rocky Mountain Dwarf Cherry," introduced to commerce from Colorado, is considered to be a seedling sand cherry. The eastern sand cherry (*Prunus pumila*) is considered far inferior to the western form. The author believes that it will prove valuable as a dwarf stock for peaches, apricots, and Japanese and native plums.

Experimental forestry: Rubber, C. F. M. SWYNNERTON (*Rhodesian Agr. Jour., 1 (1903), No. 3, pp. 50–53*).—An account of the planting and growth of several rubber-producing trees and plants in Rhodesia. The greatest success in germinating Ceara rubber seed occurred when both edges of the pointed end of each seed were ground down until the kernel was just visible. The point was also ground down slightly, taking care not to injure the germ. Most of the rubber has been planted at an elevation of 4,000 ft. Trees planted in 1900 average 13 to 14 ft. in height.

The most rubber has been obtained from these trees by pricking with an instrument resembling a spur, which was run down 3 sides of the tree. "This method produced the greatest flow of latex and damaged the tree least." The largest amount obtained from a tree was a ball about ¾ in. in diameter. Landolphia has been planted over 200 acres of virgin forest. This plant makes a slow growth and gives a low yield of rubber of good quality, and is not recommended except under special conditions.

Formalin in treating Castilloa rubber (*Agr. Bul. Straits and Federated Malay States, 2 (1903), No. 9, pp. 285, 286*).—An account is given of the treatment of latex from mature trees with formalin for the purpose of coagulating the rubber. The quality of rubber obtained was excellent, and it is thought that rubber thus treated may keep much better on account of the intimate mixture of this preservative with the rubber globules.

Hevea brasiliensis in the Malay Peninsula, S. ARDEN (*Agr. Prat. Pays Chauds, 3 (1904), Nos. 16, pp. 404–440, figs. 7; 17, pp. 550–573, figs. 6*).—A popular account of the methods observed in the culture of *Hevea brasiliensis* in the Malay Peninsula.

Extraction of gutta-percha from the leaves, W. R. DUNSTAN (*Agr. Bul. Straits and Federated Malay States, 3 (1904), I, No. 4, pp. 128–130*).—Leaves of *Palaquium pustulatum* (?) were forwarded from the Straits Settlements to London, where they were analyzed and found to contain about 2 per cent of pure gutta and a large amount of resinous substance. It is believed that had the fresh leaves been analyzed larger amounts of gutta would have been found.

Report on gutta-perchas from the Straits Settlements, W. R. Dunstan (*Agr. Bul. Straits and Federated Malay States, 3 (1904), I, No. 4, pp. 121-128*).—Analyses are given of 6 samples of gutta-percha obtained from as many different species of plants, with estimates as to the commercial value of each. The best sample was obtained from *Dichopsis gutta*, which contained 77.1 per cent gutta and 16.9 per cent resin, and was valued at about $1.50 per pound.

Para rubber in Selangor, S. Arden (*Agr. Bul. Straits and Federated Malay States, 2 (1903), No. 10, pp. 316-320*).—The author's earlier experiments indicated that the first 3 ft. of the trunk from the base of the tree contains the largest amount of latex, while if tapping is extended beyond 6 ft. from the base the latex decreases in quantity and the quality is poorer, containing a smaller amount of caoutchouc and larger proportion of resin, thus yielding a less elastic rubber. It is thus seen that the tapping area is limited, "for no matter how skillfully the wounding is accomplished the result will be a rough and broken surface which will be found difficult to work, while the disconnecting tissue will undoubtedly interrupt the flow of latex if tapping operations are repeated before cicatrization is complete."

Experiments were therefore made to determine the relative yield of rubber obtained by opening new wounds each day, beginning at 6 ft. from the base of the tree and making a V-shaped wound, and on each succeeding day tapping 6 in. lower until the base of the tree was reached; and in making a single V incision at 3 ft. from the ground and on each succeeding day reopening the wound by taking off a thin slice from the cut surface, thus taking advantage of what is termed the "wound effect" and economizing the tapping area. In one experiment 10 trees tapped according to the former method yielded 8.75 oz. of rubber in 4 days, and by the latter method 23.25 oz.

In another experiment 10 trees tapped each day with a V-shaped incision for 6 days yielded 56.75 oz. of rubber; while 10 others tapped but once with a V-shaped incision and the wound reopened each day during the same period, yielded 68.25 oz. of rubber. The experiments indicate, therefore, not only a greater amount of rubber by reopening the old wound, but a great economy in the tapping area of the tree.

Manuring Para rubber, H. N. Ridley (*Agr. Bul. Straits and Federated Malay States, 2 (1903), No. 11, p. 351*).—The value of poudrette, lime, a mixture of burnt earth and decayed leaves, burnt earth, and cow dung, respectively, as manure for Para rubber seedlings was tested. The seedling beds were made on good low-lying soil. The plant height attained in each case with the different manures is tabulated. The most effective fertilizer was cow dung. Lime did not appear to be of much benefit. From the results obtained it is believed that cow dung may profitably be used in the nursery where Para rubber seedlings are grown.

Para rubber seed, F. J. Holloway (*Agr. Bul. Straits and Federated Malay States, 2 (1903), No. 9, pp. 284, 285*).—The author states that he has tested the relative growth of a Para seed from tapped and untapped trees and can see absolutely no difference in the development of the respective seedlings. The opinion of Mr. Willis, Director of the Royal Botanic Gardens at Peradeniya, is also quoted to the same effect. Relative to tapping Para trees, experience gained in tapping 6,500 trees indicates that 1 lb. of rubber per tree can easily be obtained if the trees are tapped twice yearly.

Transplanting trees at night (*Gardening, 12 (1904), No. 279, p. 611*).—Some French experiments are cited in which large 5-year-old trees and over were successfully transplanted late in the season by planting at night, watering copiously, and wetting the branches which had young shoots 5 or 6 in. long. The transplanted trees thus treated showed almost no sign of check. Linden, walnut, grapes, and various other trees and shrubs were successfully transplanted in this manner. It is stated that the work is best done between 10 o'clock at night and 2 in the morning, and it

is desirable that the young shoots should have begun to be woody throughout half their length.

Crossing rhododendrons, O. SCHULZ (*Möller's Deut. Gärt. Ztg., 19 (1904), No. 23, pp. 271–273, figs. 4*).—*Rhododendron griffithi* was crossed with pollen from *R. arboreum hybridum* and a number of fertile seeds obtained. These germinated readily and made good plants, but it was 10 years before any of the seedlings thus obtained came into bloom. Part of the seedlings resembled the mother plant as regards flower and growth, and part the father. Illustrations are given showing the coloring and marking of some of the blooms obtained.

[New hybrid orchid] (*Gard. Chron., 3. ser., 35 (1904), No. 910, p. 360, fig. 1; Sup., pp. 1, 2*).—At the seventeenth annual exhibition of the Royal Horticultural Society of England, a hybrid orchid was exhibited by Mr. C. Vuylsteke, of Ghent, which is described as one of the most remarkable hybrids ever raised, and the most remarkable of recent years. It has been named *Odontioda* × *Vuylstekeæ* (*Cochlioda noetzliana* × *Odontoglossum pescatorei*).

The flowers resemble those of *O. pescatorei* in size and form, but with the thicker substance of the other parent and much of its reddish-orange color. "Sepals and petals broad and flatly displayed, reddish-orange on the inner two-thirds, the color having light irregular banding of white; margin of sepals and petals rose-colored; lip whitish with yellow crest; side lobes reddish-orange; front lobe spotted with red."

Manures for passion vines, J. TAYLOR (*Agr. Gaz. New South Wales, 15 (1904), No. 2, pp. 125–129*).—Manures were used according to 40 different formulas on passion vines. Some of the formulas used and the yields obtained are given. In general, manuring was found very beneficial and profitable, and complete manures gave better results than where any essential element was omitted.

FORESTRY.

The basket willow, W. F. HUBBARD (*U. S. Dept. Agr., Bureau of Forestry Bul. 46, pp. 100, pls. 7, figs. 27, map 1*).—This bulletin treats of the growing of basket willows, their preparation for use, injurious insects, and statistics of production and consumption. After tracing the general history of willow culture the author gives an account of the distribution and characteristics of the willow. The history of willow growing in the United States is outlined, and statements given regarding the present culture of osiers in this country.

Notes are given on the preparation of the holt or willow plantation, preliminary cultivation, planting, weeding and cultivation, cutting, drafting, and peeling. Suggestions are also given for improvements in culture whereby the quality of the product, as well as the yield, may be increased. The species of willow grown in the United States are said to be the Welsh or purple willow (*Salix purpurea*), the Lemley, patent Lemley or Caspian willow (*S. pruinosa acutifolia*), and varieties of the same, and the green or almond willow (*S. amygdalina*).

Tables are given showing the estimated expenditures and receipts from willows grown on upland and bottom lands. When grown upon upland an average net profit of $17.88 per acre for 14 years is estimated, while on the bottom lands subject to inundations the net return is estimated at $87.28 per acre for 12 years. An account is given of willow growing in Europe, in which considerable advance has been made in scientific willow culture, and certain facts are deduced which it is believed would be of value to the growers in this country.

Notes are given on the insects injurious to the basket willow. The bulletin concludes with statistics on the imports of raw and manufactured willow from 1855 to 1901, and also of the American production of willows and of willow basket ware.

The American forester at work, R. V. R. REYNOLDS (*Forestry and Irrig., 10 (1904), No. 5, pp. 204-213, figs. 8*).—An account is given of the forestry methods pursued by the members of the Bureau of Forestry of this Department, and the author claims that the work thus far carried on has shown the necessity for an American system of forestry based upon sound principles and a thorough knowledge of their local application. In this respect it will differ materially from forestry as pursued in Europe. European forests will offer abundant suggestions to the American forester, but they must be adapted to the local conditions present in this country. The different classes of work as subdivided in the Bureau of Forestry are briefly described.

Some practical notes on forestry, J. H. MAIDEN (*Agr. Gaz. New South Wales, 15 (1904), No. 5, pp. 442-444*).—Directions are given for the preparation of seed bed and sowing of seed for some of the more difficultly handled species of trees. The seed of a number of these species are said to germinate very slowly and to be favored by certain conditions which are described.

To facilitate transplanting and to insure against loss in some of the more tender species the author suggests the use of bamboo pots, which consist of bamboo cut into sections about 3 in. long. These are placed on end close together in the seed bed, covered with fine earth, and the seed thickly sown over them. In this way nearly every section of bamboo will have from 1 to 3 or 4 seedlings, and when the time for transplanting comes the weaker ones are removed and the better plants set in the ground in the pot. This soon decays and the young tree is not seriously affected by the removal from the seed bed. Where bamboo is not available, the author suggests the use of small flower pots or small tin cans in a similar way.

The raising of young trees from seed, T. R. SIM (*Natal Agr. Jour. and Min. Rec., 7 (1904), No. 2, pp. 129-146, figs. 8*).—Directions are given for collecting forest-tree seed and their preservation, preparation of seed beds and methods of sowing, care of the young seedlings, transplanting, etc.

The planting of trees, T. R. SIM (*Natal Agr. Jour. and Min. Rec., 7 (1904), No. 4, pp. 383-394, pl. 1, figs. 8*).—Directions are given for planting forest and ornamental trees.

Planting white pine (*Forestry and Irrig., 10 (1904), No. 6, pp. 264-267, figs. 2*).—A brief account is given of investigations carried on by the Bureau of Forestry, in which the planting of white pine in New England is shown to be commercially feasible. The information is based on U. S. Department of Agriculture, Bureau of Forestry Bulletin No. 45 (E. S. R., 16, p. 57).

Propagation of trees by means of cuttings, T. R. SIM (*Natal Agr. Jour. and Min. Rec., 7 (1904), No. 3, pp. 247-258, figs. 10*).—Directions are given for propagation of trees by means of cuttings. The different forms of cutting are described, and the results of this method of propagation, as put in practice, are shown.

While theoretically most species of trees can be propagated in this manner, yet in practice in Natal only a few can be propagated by hard-wood cuttings. Among those successfully propagated are the plane or sycamore, ash, cottonwood, Lombardy poplar, willows, white mulberry, catalpa, various species of elm, Spanish chestnut, and a number of hedge plants, such as privet, pomegranate, quince, etc. All attempts to propagate species of eucalypts, acacias, pines, cypress, maples, black locust, and honey locust have failed.

On the latest experiences as to heather plantations, C. DALGAS (*Hedeselsk. Tidsskr., 1904, No. 2-3, pp. 23-41*).—The author discusses in this paper the symbiosis between mountain pine and spruce, to which Mueller has called attention in his pamphlet On the Relation of Mountain Pine to Red Spruce in Jutland Heather Plantations, 1903 (Om Bjergfyrrens Forhold til Rödgranen i de jydske Hedekulturer, 1903), and illustrates this relation with a number of reproductions of photographs of forest plantations.—F. W. WOLL.

Reforesting the valley of the Rhone, H. Badoux (*Chron. Agr. Canton Vaud, 17 (1904), No. 7, pp. 247–249*).—An account is given of the reforesting of the Rhone Valley, the object being to break the force of the winds which sweep the valley, often causing serious injury to crops. The undertaking was the result of an agitation begun in 1890.

Plantings have been made at right angles to the axis of the valley at different distances throughout the canton. In all 68.5 hectares have been planted in 5 plantations varying in width from 50 to 100 m. In making these plantings 491,500 plants were used, 48 per cent of which were spruce, 18 per cent fir, 1.8 per cent pine, 24 per cent alder, 4.5 per cent oak, and the remainder ash, Canada poplar, and willows.

The total cost of the undertaking thus far has been $17,641, one-fourth of which was paid by the canton, about one-fourth by the general government, and the remainder charged to the various properties benefited.

The big trees and forest fires, G. F. Schwarz (*Forestry and Irrig., 10 (1904), No. 5, pp. 213, 214*).—Attention is called to the fact that the big trees of California, together with the nearly related redwood, are free from insect and fungus attacks to a very considerable degree. In addition the trees are protected to a great extent from forest fires by their thick spongy bark, which is free from pitch and not very combustible.

Although a large number of big trees have been severely burned about the base, their vitality has rarely been seriously affected. While they may not be physiologically injured, they are indirectly harmed by the change in mechanical conditions caused by large excavations at their bases. These excavations extend over a large part of the circumference, wounding the root system and rendering them liable to be overturned in severe storms.

The hardy catalpa as a farm crop, W. J. Green (*Ohio Sta. Bul. 149, pp. 69–80, figs. 8*).—Compiled notes are given on the characteristics and value of hardy catalpa, and the author gives directions for the collection of the seeds, sowing them, preparation of permanent plantations, planting, and subsequent care. This is preliminary to an extended investigation of this tree for forest planting. The station has begun growing trees for posts, poles, and railroad ties, and the intention is to extend the work so as to include a greater variety of forestry questions.

Forest thinning and its results, W. F. Hubbard (*Forestry and Irrig., 10 (1904), No. 6, pp. 268–271*).—This is the first of a series of papers by the author and deals with the theory and practice of thinning forests. The present paper gives the value and technique of thinning, being based on the practices followed in Europe.

The relation of forests to stream flow, J. W. Toumey (*U. S. Dept. Agr. Yearbook 1903, pp. 279–288*).—In this article the author considers a forest as an average growth of trees sufficiently dense to form a fairly unbroken canopy of tops and not a scattered growth of low, round-headed trees with bushes and herbage constituting a dominant type of vegetation.

The influence of such a forest on rainfall, evaporation, transpiration, the run-off of water, etc., is discussed, and in conclusion the author states that although "the forest may have, on the whole, but little appreciable effect in increasing the rainfall and the annual run-off, its economic importance in regulating the flow of streams is beyond computation.

"The great indirect value of the forest is the effect which it has in preventing wind and water erosion, thus allowing the soil on hills and mountains to remain where it is formed, and in other ways providing an adequate absorbing medium at the sources of the water courses of the country. It is the amount of water that passes into the soil, not the amount of rainfall, that makes a region garden or desert."

The reserve policy in operation, E. A. Braniff (*Forestry Quart., 2 (1904), No. 3, pp. 137–144*).—An attempt is made to show how the forest policy of the Government

is working out when put to test. The writer thinks the policy could be improved in several ways, the chief recommendations being in regard to the "lieu selections" of private and corporate lands included within the reserves and regarding the reserve management which he thinks should be turned over to the Bureau of Forestry of this Department.

The grazing problems, which at one time seemed of great importance, the writer believes are rapidly solving themselves, and so far as his observations go there is nothing in the forest policy which is unfriendly to the mining interests of the regions affected.

Forest problems of Michigan, J. H. BISSELL (*Forestry and Irrig., 10 (1904), No. 6, pp. 280, 281*).—A brief review is given of the former forest conditions of the State, contrasting them with the present condition.

From 50 to 55 per cent of the area of the entire State was originally in pine forest. The total production of pine for the State is said to have been 161,475,000,000 ft. B. M. This with the hard wood that has been lumbered represents a value of $2,649,175,000. Of the area cut over a great portion is said to be of little or no agricultural use, but is well adapted to the growing of white pine.

In order to secure the reforesting of these nonagricultural lands, the author makes a number of suggestions, among which are the repeal of all existing land laws, the acquiring by the State of all pine stump lands, the enactment of new land laws prohibiting the sale of public land except to actual homesteaders, and a policy of taxation which would encourage private owners in the improvement of their holdings.

Forest fires in Minnesota in 1903 (*Forestry and Irrig., 10 (1904), No. 6, pp. 285, 286*).—From an extract taken from the report of the chief fire warden of Minnesota it is shown that the number of forest fires reported upon in 1903 was 52, which burned over an area of 15,585 acres, causing a damage of $28,292. In addition 35 prairie fires were reported, which caused losses amounting to $4,666.

The various prosecutions that were brought under the law are briefly noted, and the cost of the enforcement of the law is shown. Appropriations for this purpose amounted during the year to $5,000, an amount which the fire warden shows is inadequate for the efficient execution of the law.

State forestry in Minnesota, C. C. ANDREWS (*Forestry and Irrig., 10 (1904), No. 5, pp. 228–230*).—An account is given of the State forestry in Minnesota and suggestions given for rendering it more extensive and efficient. For this purpose the author states that a sentiment for forest extension and preservation must be encouraged and sustained.

Forest legislation in New York (*Forestry and Irrig., 10 (1904), No. 6, pp. 273–278*).—A report is given of legislation recently enacted by the legislature of New York in which important amendments are made to the fire law; the boundaries of the Adirondack and Catskill parks are defined, and a proposed amendment to the State constitution is given by which it will become possible to secure the removal of the dead timber from State lands.

The forest interests of Ohio, W. R. LAZENBY (*Forestry and Irrig., 10 (1904), No. 5, pp. 227, 228*).—A brief account is given of proposed legislation for the State of Ohio, which is being urged by the Ohio State Forestry Society, assisted by others interested in the subject.

Some features of the Swiss forest service, A. CARY (*Forestry and Irrig., 10 (1904), No. 5, pp. 219–222*).—Some notes are given on the Swiss forestry service as it was observed by the author in a recent tour of that country. According to the report, 28 per cent of the area of the country is unproductive and 20 per cent is devoted to forestry. This area even under good management does not supply the needs of the country for timber and about $3,000,000 worth is annually imported, mostly from Austria and Germany.

A description is given of the forest system in which the relationship between the

federal government and the various cantons is shown in the forest code revised in 1902. The general oversight of all the forests within the limits of the country is given to the general government, whether the forests are the property of any public body or belong to individuals. To the cantons is left the regulation of the municipal woods and the control over private forests, subject to the veto of the federal regulations.

Among the striking regulations attention is called to the federal contribution to the salaries of the forest officers of the cantons, from 25 to 35 per cent of which are provided by the general government. In the protection work the federation may contribute from 50 to 80 per cent without sharing in the acquired title of reclaimed lands. In fire protection the government contributes half, and to the cost of the roads 20 per cent.

In this and many other ways the cooperation between the general government and the different divisions of the country is maintained. The efficiency of these methods of control varies in the different cantons as would naturally be expected.

The forests of the Hawaiian Islands, W. L. HALL (*Hawaiian Forester and Agr., 1 (1904), No. 4, pp. 84-102*).—A description is given of the forests in the Hawaiian Islands, particular attention being given to the algaroba (*Prosopis juliflora*). This species occurs near sea level and is said to have all sprung from a single tree which was introduced in 1837 and which still stands in Honolulu.

Some of the forest types occurring on the different islands are described, and notes given on some of the more important species. The causes of the rapid decline in the Hawaiian forests are said to have been overstocking, insect injury, rank growth of grasses following grazing, forest fires, and injudicious clearing.

Report of the chief of the forestry bureau, G. P. AHERN (*Ann. Rpt. Philippine Com., 1903, pt. 2, pp. 275-313, pls. 11, figs. 2*).—A report is given of the activity of the forestry bureau for the period from September 1, 1902, to August 31, 1903. A statement is given regarding the changes and present organization of the bureau, after which the work of the different divisions is reviewed at some length.

In the division of inspection the authorized force consisted at the time of the report of 4 inspectors, 20 assistant inspectors, and 128 rangers. The Philippine Islands have been divided into forest districts and at this time the number of stations was 55. Investigations of the division of forestry management are reviewed and descriptions given of some of the forests which have been under investigation. During the year covered by the report 2,430 applicants were granted licenses, an increase of 85 per cent over the number granted during the previous year.

A report is given of the investigations of the timber-testing laboratory and workshop, comparisons being given in tabular form of the results of crushing tests of a number of Philippine timbers and a number of United States species reported upon by the Bureau of Forestry of this Department.

One of the serious problems said to confront the forester of the Philippine Islands is the utilization of many of the unknown woods that grow on the islands. There are believed to be between 1,000 and 1,500 species of trees producing timber on the islands of which about 50 varieties make up 80 per cent of the timber in the market. An attempt is being made to find uses for other species in order to provide an outlet for additional kinds of timber. The author states that there have been registered in the forestry bureau 129 estates, embracing 106,647 hectares of private woodlands. The location and extent of these woodlands are shown.

A report is made on the amount of timber and forest products taken from public lands of the Philippines during the fiscal year, in which it appears that 4,740,738 cu. ft. of timber, 218,100 cu. ft. of firewood, and a large amount of miscellaneous products were collected during the year. In addition there was imported 113,483 cu. ft. of timber and 87,000 ft. B. M. were exported. A classification is given of the different varieties of timber cut, and tables are given showing the market price of timber, the receipts and expenditures of the bureau of forestry, etc.

Recommendations on policy, organization, and procedure for the Bureau of Forestry of the Philippine Islands, G. Pinchot (*Ann. Rpt. Philippine Com., 1903, pt. 2, pp. 315-325*).—A brief preliminary report is given in which recommendations are made on the organization and procedure of the bureau of forestry of the Philippine Islands, based upon the author's observations in a survey of the forests of the Philippine Islands.

Report on investigations made in Java, 1902, E. D. Merrill (*Philippine Dept. Int., Forestry Bureau Bul. 1, pp. 84, pls. 10*).—An account is given of a trip made by the author to Java in the interest of the Bureau of Forestry, descriptions given of a collection of plants that had been secured by the various field parties of the Forestry Bureau, the methods of investigating forest flora of Java are described, and notes given on the Botanical Institute at Buitenzorg.

A new hypsometer, H. D. Tieman (*Forestry Quart., 2 (1904), No. 3, pp. 145-147, pl. 1*).—A description is given of a new form of hypsometer which is believed to be an improvement on the existing forms in a number of ways. This instrument, which is used for ascertaining the height of trees, etc., makes use of a new principle in that it brings 2 points, the vertical distance between which is to be measured, and the scale rod into single parallax by means of a rotary mirror. The readings are taken very rapidly since only one sighting is necessary and the height of the tree is read off directly.

A method of timber estimating, C. Leavitt (*Forestry Quart., 2 (1904), No. 3, pp. 161-163*).—A brief description is given of a method of estimating standing timber which is said to be in actual use. This is adapted to the use of the cruiser accompanied by a compass-man. The method described is adapted to tracts of any size and by it the timber on a quarter of a section may be estimated in a single day.

The preservative treatment of wood, S. P. Sadtler (*Tech. Quart., 17 (1904), No. 2, pp. 129-144, figs. 3*).—This paper reviews the history of the development of methods of preservative treatment of wood, especial attention being given to the apparatus and methods used in impregnating wood with aluminum sulphate and ferrous sulphate made slightly basic by previous treatment with alkali, according to the Ferrell process.

Recent progress in timber preservation, H. von Schrenk (*U. S. Dept. Agr. Yearbook 1903, pp. 427-440, pls. 3, figs. 3*).—According to the author, considerable interest has been recently manifested throughout the United States on the subject of timber preservation. Directions are given for the preparation of various woods for chemical treatment, and some of the more common methods are described.

Notes are given on the cost and relative efficiency of different treatments, and the author states that it is more profitable to treat inferior cheap timbers, such as the loblolly pine and red oak, than the longleaf pine and white oak, as the latter timbers take treatment very poorly. All timber should be thoroughly seasoned before being treated, as seasoned timbers not only take treatment better and consequently have a longer period of usefulness, but are easier handled.

For the present he recommends the following preservatives: For fence posts, either charred or treated when absolutely dry with carbolineum, spirittine, or tar oil. They may also be soaked in corrosive sublimate. Telephone and telegraph poles may be treated in a like manner. For structural timbers, creosote treatment, using 10 lbs. of tar oil per cu. ft., is recommended. For railroad ties, treating with creosote, zinc chlorid, and zinc chlorid and tar oil is recommended. For piling, the tar-oil treatment is to be preferred.

SEEDS—WEEDS.

The vitality and germination of seeds, J. W. T. Duvel (*U. S. Dept. Agr., Bureau of Plant Industry Bul. 58, pp. 96, figs. 2*).—This paper treats chiefly of the conditions influencing the vitality and germination of seeds when subjected to such methods of treatment as are met with in the ordinary handling of seeds, particular

attention being paid to the effect of climate, moisture, and temperature on vitality. A discussion is given of the respiratory activities of seeds and the part played by enzyms.

In the investigations the author employed sweet corn, onion, cabbage, radish, carrot, pea, bean, pansy, phlox, tomato, watermelon, and lettuce seed. These were given a preliminary test, after which the effect of climatic conditions and of moisture and temperature were investigated. Samples of seed from the same lots were distributed to be tested under what are known as trade conditions, dry-room, and basement conditions in Porto Rico, Florida, 2 stations in Alabama, Louisiana, Indian Territory, New Hampshire, and Ann Arbor, Mich. After intervals of 128 and 251 days lots of the seed were returned for testing. They were germinated as speedily as possible and the results are given in tabular form.

Marked differences were shown in the depreciation of the vitality in the different lots as reported. It was observed that there was a close relationship between the precipitation and the loss in vitality, the deterioration in vitality being directly proportional to the total annual rainfall. The effect of moisture and temperature was studied, and it was found that most seeds if kept dry were not injured by prolonged exposures to temperatures below 37° C., it being immaterial whether the seeds were in open or in sealed bottles. If the temperature was increased beyond 37° C. the vitality was seriously affected. Seeds kept in a moist atmosphere at temperatures as high as 30° C. were considerably injured within a short period of time, and the degree of injury rises rapidly with the increase in temperature. With the same degree of saturation, the deleterious effect of moisture was as great with samples kept in open as in closed bottles.

The effect of definite quantities of moisture on the vitality of seeds when kept within certain known limits of temperature was studied, and a marked decrease in the number of germinable seeds was observed with an increase in the moisture and temperature.

A comparison was made of the methods of storing and shipping seeds in order to protect them from moisture and consequently to secure a better preservation of vitality. An attempt was made to ascertain how small quantities of seed should be packed to retain a maximum germinative energy for the longest time, what immediate external conditions are best suited to the longevity of seeds, and the effect of climatic conditions on the life of the seeds. In the first experiment duplicate samples of various kinds of seed were put up in double manila coin envelopes and in small bottles, some of the bottles being filled, others only partly full. In order to determine the immediate effect of external conditions different lots of seed were subjected to trade conditions, dry rooms, and basements, these conditions representing the usual methods of seed storage.

Samples were distributed as mentioned before and it was found that different seeds behaved very differently under identical conditions. The relative value of different methods of storing seeds in paper packets is shown by the average losses of vitality, as reported from the 8 different stations. The depreciation for trade conditions was 36.63 per cent, for dry rooms 21.19 per cent, and for basements 42.28 per cent. Comparing these general averages with the averages given from the bottle samples, it is seen that the loss for those kept in bottles was for trade conditions 3.93 per cent, dry rooms 8.08 per cent, and basements 4.51 per cent. Experiments are reported on keeping and shipping seeds in special packages in which the envelopes and bottles mentioned above were sealed with paraffin, etc. The result obtained showed decidedly in favor of protecting seeds in moist climates from the action of the atmosphere.

The author gives a discussion of the respiration of seeds and the action of enzyms in the preservation of vitality, after which he summarizes his investigations, concluding that "the life of a seed is undoubtedly dependent on many factors, but the

one important factor governing the longevity of good seed is dryness." A considerable bibliography of literature is given.

Seed testing for farmers, B. O. LONGYEAR (*Michigan Sta. Bul. 212, pp. 11, figs. 30*).—Popular directions are given for the examination of seed for impurities and testing them for their germinative ability, as well as descriptions and notes on the more common weed seed found in examining alfalfa and various clover seeds.

Trifolium incarnatum, D. FINLAYSON (*Aynsome Agr. Sta., Grange-over-Sands, Cent. Seed-Testing Lab. Farmers' Bul. 5, pp. 8, figs. 7*).—A discussion is given of the crimson clover (*T. incarnatum*) in which its value for renovating lands for hay crop, etc., is shown. Attention is called to the necessity of early cutting in case it is used as a hay crop, since the abundant hairs result in the formation of balls in the intestines of animals, frequently causing death. A description is given of the seeds of crimson clover, and the average purity and germination of a good quality of commercial seed are given. Illustrated notes are also given of the more common weed seeds which are met with as impurities in samples of clover seed.

Rice weeds in Louisiana, W. R. DODSON (*Louisiana Stas. Bul. 77, 2. ser., pp. 394–429, figs. 14*).—This bulletin describes and illustrates the more important weeds growing in the rice fields of Louisiana and gives suggestions for their destruction. It is, in a way, a continuation of a previous publication on this subject (E. S. R., 12, p. 760). A number of new weeds are described, and additional points in the eradication of others have been developed, so that this publication will take the place of the previous one.

Charlock spraying (*Jour. Bd. Agr. [London], 11 (1904), No. 3, pp. 155, 156*).—A brief summary is given of investigations carried on in 1902–3 with charlock spraying on 24 farms in the various counties in the south of Scotland. Altogether several hundred acres were sprayed, the herbicide used being a 3 per cent solution of copper sulphate at the rate of 50 gal. per acre.

It was found that one spraying under favorable circumstances would kill the charlock, but this was dependent on proper application under suitable climatic conditions. In many instances two applications at intervals of 10 days were required to completely eradicate the weed from growing cereals. There was found no necessary relation between the size of the plant and the stage when it could be most easily destroyed. In cold, backward seasons and on exposed land the charlock frequentyl comes into flower when less than 3 in. in height. Such plants are usually of slow growth, stunted, and are much more difficult to kill than when the plant is young and succulent. In cases of this kind it was found desirable to use a 4 per cent instead of a 3 per cent solution.

The destruction of wild mustard, H. HITIER (*Jour. Agr. Prat., n. ser., 7 (1904), No. 16, pp. 510, 511*).—In response to many inquiries regarding the efficiency of chemicals for the destruction of wild mustard, the author summarizes the claims put forth for different herbicides. He describes the method of preparation and application of solutions of copper sulphate, copper nitrate, iron sulphate, and iron-sulphate powder.

The time for applying the different chemicals is given, and their efficiency not only toward the wild mustard but other weeds is shown. The amount of injury which any of these chemicals produce on cereals, clover, alfalfa, etc., is said to be small. While these chemicals are claimed to be efficient for the destruction of wild mustard, the average cost is said to be rather excessive, being from $2 to $3 per acre.

A new method for the destruction of mustard, L. CAZAUX (*Prog. Agr. et Vit. (Ed. L'Est), 25 (1904), No. 18, pp. 556, 557*).—An account is given of the use of finely powdered iron sulphate spread upon the field at the rate of 200 to 300 kg. per hectare. This treatment was quite efficient in destroying the mustard and was without injury to the crops, which were barley and oats.

DISEASES OF PLANTS.

The origin of parasitism in fungi (*Jour. Bd. Agr.* [*London*], *11* (*1904*), *No. 3, pp. 152–154*).—An abstract is given of a paper by George Massee, in the *Philosophical Transactions of the Royal Society of London*, on parasitism in fungi.

It is said that the author has brought to light some of the factors which determine immunity of certain species of plants and individuals to the attack of specific fungi. The investigations seem to show that small differences in the character of the sap of the plants are probably the main determining causes as to whether the fungus shall be able to gain entrance into a plant. As a general rule it was found that, if a weak solution of sugar was introduced within a leaf and spores of any of the commoner parasitic fungi placed on the treated portion of the leaf, the fungus could penetrate and live on the sugar solution, eventually attacking the adjoining tissues. If, on the other hand, a weak solution of acids was introduced the fungus, as a rule, showed no disposition to enter.

The investigator seems to have been able to cause certain saprophytic fungi to attack living plants, and he concludes that all parasites have developed from saprophytes, and it is possible for almost any fungus living on dead vegetable matter to acquire the habit of parasitism. He cites as an illustration the fungus *Dendryphium comosum*, which until recently had not been reported as attacking living plants, but by the aid of unnatural conditions produced under glass houses has been found attacking young cucumbers in a very serious manner.

Recent observations on the loose smut of cereals, E. SCHRIBAUX (*Jour. Agr. Prat., n. ser., 7* (*1904*), *No. 15, pp. 479–482*).—A discussion is given of the biology of the loose smuts of cereals, and also the results of the author's observations. He states that the smuts penetrate the wheat plant at 2 different periods, first during germination and second during the flowering season. The infection during the flowering season is not manifested until the following year. This form of infection is what is called the internal, while the infection which takes place during germination is called external infection.

For the internal infection the hot-water treatment is said to be the only efficient means, while for preventing external infection other methods are equally as good. The spores of the smut found within the seed are less dangerous to the general crop than those adhering to it, and in cereals where the glumes remained closed, or open for a very short time, the chances for infection are rather remote. This is particularly true if flowering takes place during a period of cool weather.

Treating seed grain to prevent smut, H. O. JACOBSON ET AL. (*Rpt. Wisconsin Agr. Expt. Assoc., 1904, pp. 62–66*).—The results of treating oats with formaldehyde solutions for the prevention of smut are shown by the experience of a number of experimenters in different parts of the State. The directions given in Wisconsin Station Bulletin 98 (E. S. R., 14, p. 978) were followed in all essential details, and all the investigators report a greatly lessened amount of smut and greater yields from treated seed when comparisons were made with small areas grown from untreated seed.

Black scab of potatoes (*Bd. Agr. and Fisheries* [*London*], *Leaflet 105, pp. 4, figs. 2*).—A brief popular account is given of the black scab of potatoes (*Œdomyces leproides*), which was first reported in England in the autumn of 1900, having probably been brought to that country with potatoes imported from the Continent.

This disease, which has been previously described (E. S. R., 14, p. 1085), is characterized by the abnormal growth of the tissues about the infected portions of the tuber. The fungus seems to stimulate a rapid growth, resulting in the formation of large, irregular-shaped outgrowths of a blackish color. When potatoes are planted in soil containing the fungus the young sprouts are often attacked and their further

growth checked. It is known that the organism survives in the soil for at least 2 years and that beets and mangels are subject to attacks of the same organism, consequently, in rotation these crops should be omitted.

Rolling the tubers in sulphur and treating the infected soil with the same fungicide have given results that fully repaid the cost of material and labor. The application of quicklime, while effective, has not been as efficient as powdered sulphur. Gas lime and winter plowing have been practically useless as means of combating this disease.

Some diseases of cane specially considered in relation to the leaf-hopper pest, and to the stripping of cane, R. C. L. PERKINS (*Hawaiian Forester and Agr., 1 (1904), No. 4, pp. 80–84*).—The relation between the pineapple disease in its various forms and the injury produced by leaf-hoppers, etc., is pointed out, and notes are given on other diseases of cane in which there appears to be no connection between the disease and insect attacks.

Onion blight, H. H. WHETZEL (*New York Cornell Sta. Bul. 218, pp. 139–161, figs. 17*).—In 1903 a serious outbreak of onion blight or mildew caused by *Peronospora schleideniana* was reported. The disease seemed to spread from definite spots in the onion field where first noticed, and later investigations showed that it was rather generally distributed throughout the principal onion-growing districts of the State. The attack was so severe as to materially reduce the crop, and inquiries brought out the fact that it was prevalent the previous year and probably other years, but the fungus made its appearance so late in the season as to do comparatively little injury.

The present report is a preliminary one, designed to interest onion growers and gardeners in checking the disease, and is to be followed by investigations of the nature and control of this disease. For the prevention of the disease it is recommended that the plants be sprayed with Bordeaux mixture, attention paid to the location and drainage of the land, and raking and burning of tops after harvesting, and although there is considered little danger of distributing the disease through the seed the author recommends soaking them for 30 minutes or more in a 0.5 per cent solution of formaldehyde before sowing.

A technical account is given of the fungus causing the blight, and brief notes are given of a secondary fungus (*Macrosporium parasiticum*), which blackens the bulbs and is associated with the blight. Notes are also given on injury by onion maggot, onion thrips, and a disease known as white tips, the nature of which is not definitely known.

A new eggplant fungus, C. O. SMITH (*Jour. Mycol., 10 (1904), No. 71, pp. 98, 99, figs. 6*).—In the autumn of 1903 the author observed a disease of eggplant which proved to be new to Delaware. At first it was thought to be caused by the spot fungus (*Phyllosticta hortorum*), but subsequent investigations showed that this was not the case. The fungus producing the disease agrees so closely with *Ascochyta lycopersici* that in the absence of authentic specimens it has been referred to that species.

Inoculation experiments with pure cultures have demonstrated that this fungus is parasitic on eggplant, tomato, horse nettle, and Jamestown weed. A technical description of the organism is given.

Vitality of Pseudomonas campestris on cabbage seed, H. A. HARDING and F. C. STEWART (*Science, n. ser., 20 (1904), No. 497, pp. 55, 56*).—Investigations are reported in which it is stated that the organism causing black rot of cabbage may live on dry cabbage seed for at least 10 months.

In the experiment reported cabbage seed was wet with water into which a culture of *P. campestris* had been thoroughly stirred. The seed was then dried and stored in test tubes, some of which were plugged with cotton and others were plugged with cotton and then sealed with paraffin. Once a month the seeds were tested for the presence of living germs, and although the experiment was unfinished at the end of 10 months living germs were found both in the paraffined and unparaffined tubes,

and healthy cabbage plants inoculated with these germs showed the presence of black rot in from 1 to 3 weeks.

It was also shown that seed produced by cabbage plants infected with black rot are able to carry the organism and infect seedling plants. The details of this investigation are to be published in a forthcoming bulletin of the New York State Station.

Peach diseases, III, A. D. SELBY (*Ohio Sta. Bul. 148, pp. 55-67, pls. 7*).—This bulletin gives notes on the prevalence, surrounding conditions, and methods employed for the prevention of leaf curl and scab of the peach during recent years in Ohio, and is in continuation of notes previously given (E. S. R., 10, p. 557; 11, p. 357).

The occurrence and distribution of the leaf curl in northern Ohio for the past 11 years is traced, and an attempt made to correlate the occurrence of the disease with weather conditions. It is stated that the leaf curl was prevalent during seasons of frequent rainy days in April, May, and June. When these months were warm and fairly bright the amount of leaf curl was greatly reduced. Spraying the trees with a single application of Bordeaux mixture before the opening of the blossoms proved effective for the prevention of leaf curl, and where fungus diseases only are to be combated Bordeaux mixture is to be preferred. Where it is desired to treat the trees simultaneously for leaf curl and scale insects some of the sulphur sprays are recommended.

The results of 7 years' study of the prevalence and injury of the fruit spot or scab fungus confirm the popular opinion that this fungus is influenced in its development by the amount of rainy weather in the late summer and early fall. The severe losses that frequently follow the presence of this fungus may be largely prevented by the proper use of fungicides, and in addition to 1 spraying before the blooming period recent observations indicate that 2 applications of weak Bordeaux mixture, one about June 15 and the second 3 or 4 weeks later, will largely or entirely prevent the occurrence of scab.

Crown gall, J. B. S. NORTON (*Maryland Sta. Circ. Bul. 56, 2. ed., pp. 8, pls. 6*).—The attention of growers is called to some of the principal characteristics of the crown gall and hairy root, which are considered by some to be forms of the same disease. According to the author, the nurseries of the State, which are subject to regular inspection, are practically free from crown gall, and nurserymen are especially careful to discard infected stock when shipping. Care in the selection of stock and the use of resistant strains where known are recommended as preventive measures.

A note on the collar rot of the orange, R. A. DAVIS (*Transvaal Agr. Jour., 2 (1904), No. 6, pp. 133, 134, pl. 1*).—The author shows that the collar rot of the orange has been present in the Transvaal for a considerable time, in spite of the frequent assertion that the disease does not exist in that region.

The usual method of irrigating the orange, which consists of the formation and filling of a basin around the trunk of the tree, is held to be partially responsible for the presence of the disease. Fully nine-tenths of the orange trees are said to be suffering from the application of water around the trunks. This with the improper drainage frequently leads to disease. Where the trees have become badly infested the author recommends total destruction, but where only slightly affected it is recommended that the bark be cut away from about the spots, leaving the wood exposed for several days. If no exudation of gum be observed it may be considered that the disease has been removed and the wounds should be protected by a coating of some fungicide. So far as practicable the use of resistant stock for grafting and budding is suggested.

The sooty mold of the olive, ZACHAREWICZ (*Bul. Dir. Agr. et Com. [Tunis], 9 (1904), No. 31, pp. 208-211*).—The sooty mold of the olive, according to the author, is due to the fungus *Fumago salicina*, which develops over various portions of the tree as a black coating, from whence it gets its name. It follows the *Lecanium oleæ*.

Associated with it is another fungus (*Cycloconium oleaginum*). For combating these 2 diseases the author recommends treating the olive trees with a mixture composed of soap 1 kg., kerosene 4 liters, copper sulphate 1 kg., and water to make 100 liters. Directions are given for the preparation of this compound insecticide and fungicide, and notes are given on its efficiency, cost, etc.

The sooty mold of the olive, CHAPELLE (*Bul. Dir. Agr. et Com.* [*Tunis*], *9* (*1904*), *No. 31, p. 223*).—The author reports a successful treatment of olive trees for protection against sooty mold by spraying them with a strong Bordeaux mixture to which was added "Nicotine." This was sprayed over the trees 3 times during the season, and is said to have been very efficient in removing the fungus.

A new species of fungus-producing canker on cacao trees, A. HEMPEL (*Bol. Agr. São Paulo, 5. ser., 1904, No. 1, pp. 22–24*).—A technical description is given of *Colonectria bahiensis*, a new species of fungus which has been recently recognized in Bahia, Brazil, as parasitic on the trunk of the cacao tree. In addition to this species brief notes are given on *C. flavida*, which occurs in Trinidad and other portions of the West Indies, and on *Nectria theobromæ*, both of which are quite injurious to cacao cultivation.

A new method for the treatment of black rot, J. DUCOS (*Prog. Agr. et Vit.* (*Ed. L'Est*), *25* (*1904*), *No. 27, pp. 11–13*).—An account is given of a preventive treatment of grapes against the black-rot fungus. The author has for a number of years been pursuing a plan which, in brief, consists of spraying the vines at the time when the fungus is making its successive appearances.

In order to determine the time for spraying a few plants are left unsprayed, and whenever the spots caused by the fungus are observed on the leaves the other vines are thoroughly sprayed with a rather strong Bordeaux mixture. As a preliminary to the treatment of the vines, they are given 2 sprayings with either copper sulphate or strong Bordeaux mixture before the appearance of the leaves. In this way the author claims to have prevented attacks of black rot with 5 sprayings in 1902 and 4 in 1903.

The treatment is said to have also been efficient in preventing the occurrence of the downy mildew.

The occurrence of black rot in Marmandais, A. GUY (*Prog. Agr. et Vit.* (*Ed. L'Est*), *25* (*1904*), *No. 22, pp. 663–665*).—A report is given of investigations on the dates of appearance of the black-rot fungus in the vineyards of Marmandais. Various dates are cited as to the time of the first observation of the fungus, and data are given regarding the time of first applications of fungicides for the protection of the vines from this disease.

The first application of fungicides should be made between April 26 and May 2. The example is cited of a vineyard in which an early spraying was given, followed by other applications during the season at intervals of about 8 days, resulting in almost total absence of the disease.

The treatment of chlorosis of grapes in calcareous soils, L. VERNET (*Prog. Agr. et Vit.* (*Ed. L'Est*), *25* (*1904*), *No. 13, pp. 385, 386*).—The usual treatment for chlorosis by which iron sulphate is added to the soil is said to be most too slow in its action, and the author proposes a treatment in which there is combined action of the iron salt and a decalcification of the soil.

The method of treatment described consists of the addition of 10 kg. of commercial sulphuric acid to about 160 liters of water, and to this is added 10 kg. of sulphate of iron, which is suspended at the surface of the liquid and gradually dissolved. After solution and thorough mixing this is poured about the vines at the rate of about 2 liters to each vine, care being taken to bank up the earth about the grape vine to protect it from direct injury.

The treatment of gray rot of grapes by hydraulic lime, G. MARAIS (*Prog. Agr. et Vit.* (*Ed. L'Est*), *25* (*1904*), *No. 24, p. 704*).—The author reports having suc-

cessfully combated the gray rot of grapes due to *Botrytis cinerea* by heavy applications of powdered hydraulic lime to the vines.

Treatment for control of gray rot of grapes, E. ZACHAREWICZ (*Prog. Agr. et Vit. (Ed. L'Est), 25 (1904), No. 22, pp. 651–655, pl. 1*).—The author claims that by treating vines with a solution of copper sulphate, powdered soap, and water, followed with applications of sulphur and sulphosteatite or plaster, powdered soap, and sulphosteatite it is possible to prevent injury to grapes by *Botrytis cinerea*.

In an editorial note a doubt is expressed regarding the efficiency of the present fungicides and mixtures for the control of this disease.

The brunissure of the grape, L. RAVAZ (*Prog. Agr. et Vit. (Ed. L'Est), 25 (1904), No. 3, pp. 69–72, figs. 6*).—The author briefly describes the brunissure of the grape, which he holds is not of fungus or bacterial origin, but is due to a weakened condition of the plant resulting from overbearing.

Notes on verdigris in combating grape mildew, E. CHUARD and C. DUSSERRE (*Chron. Agr. Canton Vaud, 17 (1904), No. 9, pp. 291–297*).—Studies are given of the relative value of 2 forms of verdigris which are in common use as fungicides for use in preventing grape mildew. One, which is called neutral or refined verdigris, contains from 31 to 32 per cent copper and is distinguished by its ready solubility in water, while the second form, known as basic or adherent verdigris, is less soluble in water and remains in suspension for a considerable time. It is less rich in copper, containing only 23 or 24 per cent on an average.

The experiments conducted with these fungicides showed that the soluble verdigris was more easy of application, did not present any visible traces after some little time, nor was it washed off by rains if the treatment was given the vines at a time when they were completely dry. A 0.5 per cent solution gave results as satisfactory as when a more concentrated form was employed.

The results of an investigation with grape mildew and its treatment in 1903, E. CHUARD and H. FAES (*Chron. Agr. Canton Vaud, 17 (1904), No. 8, Sup., pp. 51*).—The results of an investigation into the mildew of grapes, times of its invasion in different regions, methods of treatment and their results, and conclusions regarding this disease are given.

Much of the information published is based on returns received from circular letters sent out to correspondents throughout every grape region of Switzerland. Formulas for the preparation of fungicides and directions for application are given, and it is concluded that the proper use of fungicides, even in years when mildew is very prevalent, reduces the amount of injury to a great extent.

The wintering of the powdery mildew of the grape, G. DE ISTVANFFI (*Bul. Agr. Algérie et Tunisie, 10 (1904), No. 6, pp. 130–132*).—The importance of determining the method by which the powdery mildew is carried over from one season to another has led to numerous investigations.

In Europe this fungus seldom produces the perithecial form and consequently must have some other method of propagation. The author reports having observed in October the mycelium of the fungus as well as its conidial stage on buds which were produced on late shoots. The microscopical examination of the tissues of these buds showed that the fungus had penetrated them and fructified. Cuttings of vines attacked by the mildew in autumn were collected through the winter which showed a presence of the mycelium in considerable quantity. A third method of spending the winter is said to be on the dried clusters of grapes remaining on the vines. An examination made in January and February showed the mycelium quite abundant.

Based upon the author's investigations, he recommends for the destruction of this fungus winter treatment of vines and the collection of all dried clusters, etc.

Occurrence and treatment of grape powdery mildew, L. RAVAZ (*Prog. Agr. et Vit. (Ed. L'Est), 25 (1904), No. 22, pp. 645–651*).—The author reviews the recent publications of Istvanffi (see above) regarding the method by which the grape pow-

dery mildew is carried over in its conidial phase from season to season, and gives the results of some of his own observations upon the subject.

As far as the author's information goes, he has never been able to find any conidia of the fungus on the shoots or bark, although they have been more or less covered with the mycelium. The buds seem to be a common abiding place for the fungus during the winter time and the disease is frequently first observed upon the stipules.

In attempting to combat this disease the author states that the reason why some fungicides are not efficient is that they do not thoroughly wet the plant. On this account Bordeaux mixture and some of the more adhesive fungicides are inadequate, but if the leaves and bunches of fruit are thoroughly wet with a fungicide it is possible to control the mildew.

On the simultaneous treatment of the powdery and downy mildew, E. CHUARD and C. DUSSERRE (*Chron. Agr. Canton Vaud, 17 (1904), No. 11, pp. 329–332*).—Spraying grapevines with a fungicide composed of Bordeaux mixture to which is added a form of sulphur, which the authors state is easily wet with water, is recommended as a treatment for the prevention of both the powdery and downy mildew.

This form of sulphur is said to be in the market in 2 qualities, one, which is used as a simple mixture and is applied at the rate of 1 to 3 kg. per 100 liters of Bordeaux mixture, and a second, which contains a portion of carbonate of soda. It is also said that the sulphur may be used with Burgundy mixture, verdigris solutions, etc.

Destruction of grape buds by copper sulphate, L. VERNET (*Prog. Agr. et Vit. (Ed. L'Est), 25 (1904), No. 15, pp. 467, 468*).—In order to protect grapes against late spring frosts it is a common practice to cover them with screens of coarse bagging. These are very commonly dipped in a 5 per cent solution of copper sulphate to protect them against mildew, etc., and prolong their durability.

The author states that dew and rain falling upon the screens cause the copper sulphate to go into solution and drop through upon the vines, frequently burning and destroying the buds. In order to prevent this injury he recommends soaking the screens in eau celeste. Rain or dew falling upon this does not make as injurious a fungicide and at the same time the screens protect the buds.

A disease of coniferous trees, P. VAN BIERVLIET (*Rev. Gén. Agron. [Louvain], 13 (1904), No. 4, pp. 166–168*).—An account is given of attacks on spruce, silver fir, and other coniferous trees by *Botrytis douglasii.* As a preventive measure the author recommends the burning of the diseased trees, and where possible spraying with a fungicide composed of copper sulphate 900 gm., copper carbonate 1,360 gm., potassium permanganate 85 gm., soft soap 225 gm., and rain water 80 liters.

Two fungi growing in holes made by wood-boring insects, P. SPAULDING (*Missouri Bot. Garden Rpt. 1904, pp. 73–77, pls. 3*).—An account is given of 2 species of fleshy fungi which were observed in the long-leaf pine district of eastern Texas in a region where *Pinus palustris* is exclusively cut for timber. After lumbering, the tops and small logs are left on the ground to rot and this material is the home of a great number of wood-boring insects; one species in particular is very abundant, making a hole about ¼ in. in diameter. On many small logs were found fungi of the Agaricus type, and upon being submitted to Prof. Charles H. Peck they were identified as *Flammula sapineus* and *Claudopus nidulans.*

The fungus mycelium was found in every instance to extend but a short distance into the portions which were filled with a mass of wood fiber which had been chewed up by the borer. The mycelium was found only in the somewhat decayed material in the burrows and apparently never entered into the wood which bounds the opening left by the grub. Similar instances are sighted of other fungi which are associated with bark-boring and other insects.

Revised plant import regulations, C. P. LOUNSBURY (*Agr. Jour. Cape Good Hope, 24 (1904), No. 6, pp. 702–707*).—After calling attention to the necessity for the inspection of nursery stock and the dangers from the introduction of diseases, the author

gives the regulations under which plants may be introduced into South Africa, discussing them at some length.

Preparation and use of fungicides (*Chron. Agr. Canton Vaud, 17 (1904), No. 10, pp. 311–315*).—Directions are given for the preparation of Bordeaux mixture, Burgundy mixture, and neutral and adherent verdigris, the quantity of each fungicide to be used, time for its application, etc., being indicated.

ENTOMOLOGY.

The attraction of colors and odors for insects, J. Pérez (*Mem. Soc. Sci. Phys. et Nat. Bordeaux, 6. ser., 3 (1903), pp. 1–36*).—Observations were made on honeybees, bumblebees, syrphus flies, and many other insects for the purpose of determining the influence of the odor and color of flowers upon the visitation of insects. It was found that bees do not always confine themselves to any one species of plant during a given flight. Such is the case especially when pollen is being collected. In Hymenoptera other than bees, it was observed that the insects confined their attention largely to one family of plants.

Injurious insects, E. Fleutiaux (*Agr. Prat. Pays Chauds, 3 (1903), Nos. 14, pp. 241–252; 15, pp. 372–376; 3 (1904), Nos. 16, pp. 495–502; 17, pp. 623–627, figs. 6*).—Descriptive and economic notes are given on various insects injurious to sweet potatoes, cassava, chickpea, beans, sorghum, cocoanut, cacao, banana, and other tropical plants.

Insects injurious to cultivated plants, F. Corboz (*Chron. Agr. Canton Vaud, 17 (1904), No. 11, pp. 338–341*).—Notes on the injurious effects and means of combating brown-tail moth, *Cossus ligniperda*, *Hybernia defoliaria*, *Agrotis segetum*, etc.

Insect injuries to hardwood forest trees, A. D. Hopkins (*U. S. Dept. Agr. Yearbook 1903, pp. 313–328, pl. 1, figs. 17*).—The author discusses the habits, life history, and means of combating a number of the most important insect enemies of hardwood trees. The hickory-bark beetle may be controlled by cutting and burning the bark of infested trees before the middle of May of each season. The oak-bark beetle is to be controlled by felling infested trees, removing the bark from the trunks, and burning the branches. Notes are also given on cherry-bark beetle, two-lined chestnut borer, oak-timber worm, carpenter worm, etc.

Powder-post injury to seasoned wood products, A. D. Hopkins (*U. S. Dept. Agr., Division of Entomology Circ. 55, pp. 5*).—The character of the injury caused by so-called powder-post beetles and the extent of losses thus produced are briefly described. The damage of this sort is caused by several species of insects which burrow in seasoned wood. In general the winter is passed in the dry wood. The eggs are deposited in the spring and the larvæ begin work at once. Sapwood which has been stored in one place for 2 or more years and manufactured wood articles are most frequently injured.

In preventing losses from these pests it is recommended that infested pieces of wood and lumber be destroyed or treated with kerosene, or by steaming or subjection to dry heat. It is also suggested that lumber yards be frequently inspected to detect the presence of the insect.

Catalogue of exhibits of insect enemies of forests and forest products at Louisiana Purchase Exposition, St. Louis, Mo., 1904, A. D. Hopkins (*U. S. Dept. Agr., Division of Entomology Bul. 48, pp. 56, pls. 22*).—The object of the exhibit is to show the most important forest insects and the nature of their injuries to trees and woods. The exhibit is classified according to geographical distribution and systematic position of the host plants and insects.

Some insects that attack fruit trees in the spring, T. B. Symons (*Maryland Sta. Circ. Bul. 57, pp. 8, figs. 9*).—Attention is called to the necessity of making careful observations in the spring in order to prevent the ravages of injurious insects

upon fruit trees. Notes are given on the appearance, habits, life history, and means of combating apple aphis, codling moth, tent caterpillar, plum curculio, fruit-tree bark-beetle, flat-headed apple-tree borer, and peach-tree borer.

Report of the State entomologist, R. A. Cooley (*Montana Sta. Bul. 51, pp. 199–274, pls. 8, figs. 10*).—Detailed notes are presented on the appearance, habits, life history, distribution, natural enemies, and means of combating the most important species of injurious insects in Montana, including bud moth, oyster-shell bark-louse, apple aphis, flat-headed apple-tree borer, pear-leaf blister-mite, and grasshoppers. The author discusses also the economic value of toads and presents a brief list of Montana fruit pests with notes on insecticides and fungicides.

Bulletin of the commission of agricultural parasitology (*Bol. Com. Par. Agr., 2 (1904), No. 4, pp. 143–206, pls. 9, fig. 1*).—Biological and economic notes are presented on various injurious insects of grapes and other crops, protection of insectivorous birds, cotton-boll weevil, pyrethrum insect powder, etc.

The status of the Mexican cotton-boll weevil in the United States in 1903, W. D. Hunter (*U. S. Dept. Agr. Yearbook 1903, pp. 205–214, pls. 5, fig. 1*).—A brief account of the distribution, depredation, life history, and means of controlling this pest.

The author believes that no direct insecticide methods such as the use of poisons will be effective in destroying the pest. Neither is any hope entertained of great help from the use of fungus diseases or resistant varieties of cotton. Apparently the greatest reliance must be placed in proper cultural methods such as the early destruction of plants in the fall and hastening the maturity of the crop in order to avoid the attacks of the weevils.

The Mexican cotton-boll weevil, H. A. Morgan (*Proc. Louisiana State Agr. Soc. and Stockbreeders' Assoc., 1904, pp. 64–71*).—The conditions of the weevil problem in Texas and Louisiana are briefly outlined. The habits, life history, distribution, and means of combating the pest are also discussed.

An enemy of the cotton-boll weevil, O. F. Cook (*U. S. Dept. Agr. Rpt. 78, pp. 7*).—While studying the varieties of cotton grown by Indians in Guatemala, the author discovered that a large reddish-brown ant which normally visits the cotton plants for the purpose of feeding upon the nectar secreted by the leaves and other parts of the plant also attacks the cotton-boll weevil and destroys it by stinging and injecting a poisonous substance.

The author believes that the successful cultivation of cotton by the Indians of Alta Vera Paz is made possible by the assistance of ants in destroying the cotton-boll weevil. Brief notes are given on the habits of this ant.

Grasshoppers in alfalfa fields, S. B. Doten (*Nevada Sta. Bul. 57, pp. 6, pls. 2*).—Grasshoppers are considered the most injurious insects in the State of Nevada. They do greatest damage to the second crop of alfalfa. Notes are given on the habits and life history of the pests. Deep fall plowing is recommended for the destruction of the eggs. Fall plowing is more effective than spring plowing. Harrowing in the spring destroys a considerable proportion of the eggs. The use of poisoned baits and various forms of hopperdozers is also recommended.

Combating wireworms in cereals, G. Caruso (*Atti R. Accad. Econ. Agr. Georg. Firenze, 4. ser., 26 (1903), No. 4, pp. 373–380*).—Tests were made of fertilizers, white mustard, and lupines in determining their value for preventing the attacks of wireworms in cereal fields. The wireworms were found to be most numerous in the first 30 cm. of soil and most injurious during fall and winter. Oil of tar sprayed on the soil at the rate of 25 kg. per hectare had no effect on the wireworms. Lupines, however, checked them to a considerable extent.

Black grub or cutworm, E. E. Green (*Circs. and Agr. Jour. Roy. Bot. Gard., Ceylon, 2 (1904), No. 11, pp. 2*).—Brief mention is made of the usual mechanical and chemical methods of combating cutworms.

Grubs on oats (*Jour. Bd. Agr.* [*London*], *11* (*1904*), *No. 4*, *pp. 215, 216*).—For preventing injury to oats from crane-fly larvæ it is recommended that the ground be thoroughly ploughed in June or July, and that the soil be treated with gas lime at the rate of 3 or 4 tons per acre.

The western cricket, S. B. Doten (*Nevada Sta. Bul. 56, pp. 18, pl. 1*).—A study was made of the life history of *Anabrus simplex* for the purpose of learning a successful method of combating the pest. The crickets invade cultivated fields from the grazing lands and foothills. They may be checked and destroyed by water in irrigation ditches. Trenches with vertical sides serve to prevent the further progress of the insects. Kerosene appears to have but little effect on them. Poisoned horse dung or poisoned bran is an efficient means of destroying the pests. The most certain method of protecting fields against the attacks of crickets consists in the use of barriers of oilcloth or tin. The tin may be obtained from kerosene cans and should be about 12 in. high. The crickets are unable to jump over it.

In Nevada much damage is done to alfalfa. The crickets move in immense armies and seem to withstand very inclement weather. The eggs are deposited in the soil of the lower foothills. The crickets reach full size about the middle of July.

The nut-grass coccid, W. W. Froggatt (*Agr. Gaz. New South Wales, 15* (*1904*), *No. 5, pp. 407–410*).—*Cyperus rotundus*, known as nut grass, is considered one of the worst weeds in New South Wales. This weed has been held in check and, in some localities, quite exterminated by a scale insect (*Antonina australis*), which infests the roots of the plant. The habits and life history of the insect are described.

Destruction of slugs, S. Mottet (*Ann. Soc. Agr., Loire, 2. ser., 23* (*1903*), *Nos. 3, p. 202; 4, p. 236*).—Dusting with ashes or lime is recommended. Slugs have the habit of collecting under some protection during the daytime and may be readily destroyed in such situations.

Results of practical experiments with peach borer, C. C. Newman (*South Carolina Sta. Bul. 83, pp. 9*).—On account of the general prevalence of this pest in Scuth Carolina, experiments were undertaken to control it. As a result of these experiments it is recommended that the soil be removed about the base of the peach trees in the fall and that the trunks be coated with a wash containing lime, whale-oil soap, sulphur, and Paris green. This process should be repeated about the middle of March. Detailed directions are given for preparing the wash and notes are presented on the habits and life history of the pest. The careful inspection of nursery stock is also recommended.

The gypsy moth, P. Lesne (*Jour. Agr. Prat., n. ser., 7* (*1904*), *No. 26, pp. 836, 837, figs. 3*).—The habits and life history of this pest are briefly noted. It recently defoliated oak trees over large areas in Hungary. The usual remedies are recommended, preference being given to destruction of the eggs.

Studies on the transformations of saturnian moths, with notes on the life history and affinities of Brahmæa japonica, A. S. Packard (*Proc. Amer. Acad. Arts and Sci., 39* (*1904*), *No. 22, pp. 547–578*).—Detailed biological and economic notes are given on a number of species of the family Saturniidæ, with an account of their habits and structure.

The tea tortrix, E. E. Green (*Circs. and Agr. Jour. Roy. Bot. Gard., Ceylon, 2* (*1903*), *No. 3, pp. 33–46, pl. 1, fig. 1*).—*Capua coffearia* has caused serious damage to tea since 1889. The insect is described in all its stages, and notes are given on its food plants, distribution, and natural enemies. There are about 6 broods per year. Collection and destruction of the eggs is considered the most effective remedy.

Shot-hole borer, E. E. Green (*Circs. and Agr. Jour. Roy. Bot. Gard., Ceylon, 2* (*1903*), *No. 9, pp. 141–156, figs. 7*).—The appearance, habits, and life history of *Xyleborus fornicatus* are discussed, with notes on its food plants, natural enemies, distribution, and means of repression. This beetle is particularly injurious to tea plants.

The pest may best be combated by thorough pruning and destruction of infested wood, combined with the rational use of fertilizers.

The "lobster caterpillar," E. E. GREEN (*Circs. and Agr. Jour. Roy. Bot. Gard., Ceylon, 2 (1903), No. 5, pp. 97–107, pls. 3*).—Notes are given on the habits, life history, and injurious attacks of *Stauropus alternus*, which is usually considered a rare species or of no economic importance. It has recently caused great damage to tea in the Kalutara district. The distribution, natural enemies, and food plants of the pest are also discussed. It may best be treated by thorough pruning and the use of arsenical sprays.

Parasites of coffee in New Caledonia, SPIRE (*Agr. Prat. Pays Chauds, 3 (1904), No. 16, pp. 480–483.*)—Attention is called to the scarcity of literature on this subject. The author presents notes on the habits, life history, and means of combating cockchafers, *Aphis coffeæ*, and certain leaf-eating caterpillars.

Cocoanut beetles, L. C. BROWN (*Agr. Bul. Straits and Federated Malay States, 2 (1903), No. 2, pp. 65–67*).—Notes are presented on *Rhynchophorus ferrugineus* and *Oryctes rhinoceros*. The former, or red beetle, is very injurious to the cabbage in its larval stage. The burrows of the second species offer an opportunity for the first species to attack the trees. In combating these pests it is usually sufficient and practicable to dig out the beetles from infested trees.

Cabbage diseases and insects, J. B. S. NORTON and T. B. SYMONS (*Maryland Sta. Circ. Bul. 58, pp. 10, figs. 6*).—Descriptive and biological notes are given on club root, black rot, soft rot, wilt, and mildew of cabbage. The authors also describe and mention the chief means of combating a number of injurious insects including imported cabbage butterfly, cabbage plusia, cabbage mamestra, diamond-back moth, harlequin cabbage bug, and cabbage aphis.

A castor-oil pest (*Agr. Bul. Straits and Federated Malay States, 3 (1904), No. 1, pp. 22, 23*).—*Ophiusa melicerte* and *O. serva* are reported as very injurious to castor bean, the caterpillars devouring nearly the whole plant. It is recommended that the caterpillars be shaken into nets or cloths and also caught by means of lantern traps.

Elm-leaf beetle, P. L. LESNE (*Jour. Agr. Prat., n. ser., 7 (1904), No. 14, pp. 456–460, pl. 1*).—A history is given of some of the most serious outbreaks of this pest in France. The habits and life history of the insect are described. Formulas are presented for the preparation of arsenical and contact insecticides. Preference is given to the latter class of remedies. The most convenient means of spraying trees are also briefly described.

Catching insects with lantern traps, D. BELLET (*Jour. Agr. Prat., n. ser., 7 (1904), No. 13, pp. 415, 416*).—A brief review of the work done in the United States with lantern traps.

A new wash for scale insects (*Bul. Dept. Agr. Jamaica, 2 (1904), No. 5, pp. 110, 111*).—A brief review is given of the work along this line in Georgia, Connecticut, and Illinois. Various formulas are suggested for the preparation of lime-salt-sulphur wash.

Fungicides, insecticides, and spraying calendar, G. E. STONE, H. T. FERNALD, and F. A. WAUGH (*Massachusetts Sta. Bul. 96, pp. 16, fig. 1*).—Formulas are given for guidance in the preparation of the most important insecticides and fungicides, including materials used in fumigation. Directions are also given for the preparation of mixtures of insecticides and fungicides. Suitable treatment is recommended for insect pests and fungus diseases of greenhouse plants. A general outline is given for treatment of the common fruits and garden vegetables.

Revised plant import regulations, C. P. LOUNSBURY (*Agr. Jour. Cape Good Hope, 24 (1904), No. 6, pp. 702–707*).—It is urged that the conditions in South Africa fully justify drastic measures to prevent the further introduction of insect pests and fungus diseases. A copy is given of the revised law of Cape Colony relating to this

matter. The law provides for the compulsory fumigation of all imported trees and woody plants.

Formaldehyde fumes and steam according to the method of Esmarch, KISTER and TRAUTMANN (*Ztschr. Hyg. u. Infectionskrank., 46 (1904), No. 3, pp. 379-393*).—The authors tested Esmarch's method, which consists in a combination of a disinfectant, such as formaldehyde, heat, and vacuum. Under ordinary conditions formaldehyde fumes were found to have little penetrating power. Insects such as fleas, flies, and bedbugs were killed when the temperature reached 60-70° C. in the room, but remained alive at 40° C. Moist heat combined with formaldehyde fumes seemed to be very effective in destroying bacteria and household insects.

Directions for mailing insects, E. D. SANDERSON (*Texas Sta. Circ. 9, p. 1*).—Specific directions are given regarding the manner of packing and shipping insects so as to comply with the regulation of the Post-Office Department and so as to secure the safe arrival of the insects.

The study of "insects" in the public schools, T. B. SYMONS (*Maryland Sta. Circ. Bul. 55, pp. 13, figs. 15*).—In the author's opinion entomology is peculiarly adapted to fill a place in nature study in the public schools. The variety of species is very great and material for study is easily obtained. The general biological laws may be conveniently studied in insects. Directions are given for collecting, preserving, and studying insects. The bulletin is intended as a guide to teachers in the collection and study of insects and in class-room demonstrations.

The destruction of white ants, A. LOIR (*Agr. Prat. Pays Chauds, 3 (1903), No. 13, pp. 19-31, figs. 4*).—The various forms of individuals in white-ant colonies are described in detail, and notes are given on the habits, natural enemies, and means of combating these pests. Bisulphid of carbon and SO_3 are recommended for destroying the insects in their tunnels.

The botfly, R. E. WEIR (*Jour. Dept. Agr. West Australia, 9 (1904), No. 1, pp. 17, 18*).—This insect appears to be increasing in numbers in West Australia. The symptoms of infestation are briefly described. Formulas are given for medicinal treatment of infested horses.

Preventive and remedial measures against mosquitoes, C. B. SIMPSON (*Transvaal Agr. Jour., 2 (1904), No. 7, pp. 354-357*).—The author recommends the usual remedies, such as drainage, use of kerosene, and screens for destroying larval and adult mosquitoes.

Fighting mosquitoes in California, H. A. CRAFTS (*Amer. Inventor, 12 (1904), No. 14, p. 310*).—Brief notes on the work of the California Experiment Station in exterminating mosquitoes.

Bee keeping, R. WEST (*Jour. Jamaica Agr. Soc., 8 (1904), No. 6, pp. 223-226*).—The author discusses the characteristics and comparative advantages of different races of bees and the management of queens.

Bee keeping, R. WEST (*Jour. Jamaica Agr. Soc., 8 (1904), No. 7, pp. 282-284*).—Attention is called to the importance of a proper selection of bees in order to obtain vigorous colonies with long-lived individuals and increased honey-gathering power.

Bee notes, J. SUTTON (*Jour. Dept. Agr. West. Australia, 9 (1904), No. 3, pp. 145-147*).—The past season has been unfavorable to honey production on account of the protracted drought and prevalence of bee diseases. In some localities the bee hives were invaded by ants. It was found to be a comparatively simple matter to destroy these insects in their nests.

Means of improving the races of bees, E. VAN HAY (*Rev. Gén. Agron. [Louvain], 13 (1904), No. 1, pp. 43-48*).—Honey production may be increased by proper selection of bees of a given race, by judicious crossing of different races, and by the use of improved apparatus. Brief mention is made of the chief desiderate in a profitable swarm of bees. Notes are also given on experiments for the purpose of increasing the length of the tongue of bees.

The United States Department of Agriculture and silk culture, L. O. HOWARD (*U. S. Dept. Agr. Yearbook 1903, pp. 137-148, pls. 5*).—A historical statement is given of the various efforts which have been made in this country to establish the raising of silk worms upon a profitable basis. The present work of the Department along this line began July 1, 1902, and has involved an inspection of methods of silk raising in southern Europe, the purchase of cocoons by the Department, and experiments in reeling silk.

The outlook for a natural market for cocoons in this country is considered problematical but rather hopeful. In order to show the economic importance of raising our own raw silk, statistical data are presented concerning the importation of raw silk during the years 1892 to 1902.

FOODS—NUTRITION.

Entire wheat flour, C. D. WOODS and L. H. MERRILL (*Maine Sta. Bul. 103, pp. 61-76, pl. 1*).—The results of studies upon the milling of wheat, chemical composition, digestibility, and nutritive value of so-called entire wheat, Graham, and ordinary flours are summarized and discussed. The fact is pointed out that the introduction of the roller process of milling has made it possible to utilize hard spring wheats rich in gluten and to include in the straight or standard patent flour a considerable portion of the grain which in the old process of milling was lost in bran and middlings. It is noted that "this has materially improved the bread flours in common use until the standard flours from hard wheat carry more protein than almost any Graham flour in the market 25 years ago, and as much or more than many Graham flours now on the market. Furthermore, the demand for bread flour of high gluten content has stimulated wheat breeding and the growing of hard wheat, so that even winter wheats are now grown which in gluten content rival the hard spring wheats of the Northwest."

Analyses of cleaned wheat and bran from entire-wheat flour and from straight-grade flour are reported. These analyses and microscopical studies showed that the brans from the 2 sorts of flour were "as nearly identical as 2 brans from the same kind of milling and the same wheat would be likely to run."

According to the authors' calculations 100 lbs. of cleaned wheat will, with modern methods of milling, yield very nearly 100 lbs. of Graham flour, about 85 lbs. of entire-wheat flour with 15 lbs. of bran, or about 72 lbs. of straight or patent flours with 13 lbs. middlings and low-grade flour and 15 lbs. bran. In other words, the entire-wheat flour and the standard patent flour differ from each other only in that the former contains the middlings and low-grade flour, the bran being omitted from both.

"It therefore follows that whatever of nutritive value there is in entire-wheat flour that is lacking in patent flour must be sought for in the middlings and low-grade flours. These materials are usually higher in protein content than the straight flour. The protein of the most importance in wheat flours is in the form of gluten. The gluten of second clear flour is of poor quality and on this account this grade of flour makes a heavy loaf. The red-dog flour is obtained from the germ or embryo and adjacent parts of the kernel. While usually high in protein, it is dark in color, and because of the poor quality of its gluten has little expansive power and makes a very inferior loaf. The middlings contain much of the germ, the aleurone layer of the bran, and finely ground particles of the outer coatings. It is usually high in protein content, but with practically no gluten.

"It is probable that much of the laxative qualities noticed in Graham flour and which Lawes and Gilbert attributed to the coarse particles of bran, are in reality due to the character of the protein and mineral compounds of the aleurone layer and the germ. For while entire-wheat flour is not so much of a laxative as Graham, it pos-

sesses this property to such a degree that the claims made by some manufacturers that it is a 'complete remedy for constipation' would probably hold true in most cases.

"The low-grade flours and the middlings carry quite high percentages of ash which are valuable in nutrition. All these nutrients found in the low-grade flour and middlings enter into the entire-wheat flour, and upon them depend the differences between entire wheat flour and patent flour."

Studies on the nutritive value of different sorts of bread carried on in cooperation with this Department are summarized. (See below.)

A milling experiment with entire-wheat flour, C. D. Woods and L. H. Merrill (*Maine Sta. Bul. 103, pp. 77–80*).—The details of a milling experiment are reported in which so-called entire-wheat flour was ground from No. 1 hard northwestern spring wheat.

"At this mill, and at all mills where we have been given definite information, the cleaned wheat is crushed between rollers and purified in the same way as in the manufacture of patent flour, with the exception that all the product other than the bran is included in the flour."

From the 1,031 lbs. of wheat ground 81.9 per cent entire-wheat flour and 17.5 per cent bran were obtained, the loss in milling being 0.6 per cent. The yield of bran was somewhat smaller than usual according to available data. The authors note that it was well cleaned and that the yield could not have been greatly increased with this particular wheat with further treatment. "On the other hand, the flour contained less crude fiber than most samples of entire-wheat flour examined at this station, and under the microscope there was less of the outer layers of bran cells than in most flours of this class. . . . Apparently the flour differed from straight patent flour only in containing the middlings, red-dog, and second clear flours, which are kept out of the high-grade patent."

Analyses of the wheat, flour, and bran are reported. Of the total nitrogen of the wheat 80 per cent was found in the flour and 20 per cent in the bran. In the case of ash 42.5 per cent was found in the flour and 57.5 per cent in the bran.

Wheat flour and bread, H. Snyder and C. D. Woods (*U. S. Dept. Agr. Yearbook 1903, pp. 347–362*).—Some of the data obtained in experiments carried on in cooperation with this Office are summarized and discussed. According to the authors, "while the coarser grades are not more nutritious than the finer flours, there are many cases in which they are especially desirable, as, for instance, for persons of sedentary habit and occupation, because their stimulating of the alimentary tract may help to procure a larger secretion of the digestive juices and also to overcome a tendency to constipation. This, however, is a purely physiological action, and should be considered apart from the nutritive value.

"Finally, it may be said that wheat flour of all the various grades is one of the cheapest, most digestible, and most nutritious of human foods, and well worthy of the high estimation in which it is generally held. The use of different sorts of wheat flour is a convenient way of giving variety to the diet, a matter which is of no little importance."

Studies on the digestibility and nutritive value of bread, C. D. Woods and L. H. Merrill (*U. S. Dept. Agr., Office of Experiment Stations Bul. 143, pp. 77*).—The results of a number of natural and artificial digestion experiments with bread made from standard patent, whole wheat, and Graham flour, ground from the same lots of wheat, were in accord with those obtained in earlier investigations of this series (E. S. R., 15, p. 63), and showed that the patent flour is slightly inferior to the coarser flour as regards composition, but is superior as regards digestibility, so that in general it may be said that bread made from all the common grades of flour is quite thoroughly digested and differs little in nutritive value. The investigations emphasize the fact that breads of all sorts are among the most useful and economical

articles of diet. In connection with the digestion experiments the income and outgo of nitrogen was determined.

Digestion experiments depend for their success quite largely upon an accurate separation of the feces, and different methods of accomplishing this were tested, including the use of knotted strings and of lampblack in gelatin capsules, some of which were treated with shellac, tannin, and formaldehyde, i. e., substances designed to retard the solution of the capsule in the stomach. None of the markers tested proved entirely satisfactory.

"While too great reliance should not be placed on a marker of any kind, as shown by the results of a large number of experiments, lampblack, when properly used, has given tolerably good results, and may be considered a valuable aid in the separation of feces. The texture of the feces and the time of their appearance (if the subject be of regular habits) are factors which must be considered of equally great importance.

"In digestion experiments reliable results can be hoped for only when the experimental period is fairly long, at least four days, and the subjects are of regular habits. Regularity is a matter of the greatest importance, since feces can rarely be so marked that separations can safely be made by color alone. Increased accuracy may be obtained when evacuations take place daily and at about the same hour. Retention of the intestinal contents beyond the usual period appears often to result in greater displacement of different portions of the feces than would otherwise be likely."

Report of the food commissioner, E. F. Ladd (*North Dakota Sta. Rpt. 1903, pp. 132–228*).—Under the provisions of the State pure-food law 268 samples of foods were examined for the detection of adulteration or sophistication, the period covered by the work including 6 months. The total number of samples examined, the author states, was larger than for the preceding year, "but the percentage of adulterated goods has been reduced from 72 to 32 per cent. The most marked change has been found in preserves, jams, jellies, etc. Where one year ago every sample examined was adulterated, now but 30 per cent are found to be illegal. We may add also that the quality has been proportionately improved."

Analyses are reported of a number of samples of canned and potted meats, spices, and teas. The report also contains a summary of court cases and some data regarding the State pure-food law.

Foods, T. S. Dymond and F. Hughes (*Essex Education Com., Notes Agr. Anal. County Tech. Labs., 1901–1903, pp. 22–31, 40–46*).—Analyses are reported of a number of feeding stuffs, samples of milk, and potable and other waters.

Foods and food control, W. D. Bigelow (*U. S. Dept. Agr., Bureau of Chemistry Bul. 69, pt. 6, pp. 463–503*).—This bulletin contains a digest of the food laws in force in the United States on July 1, 1902, and also serves as an index to the compilation of these laws contained in the parts previously published (E. S. R., 14, p. 683).

Foods and food control. I, Legislation during the year ended July 1, 1903, W. D. Bigelow (*U. S. Dept. Agr., Bureau of Chemistry Bul. 83, pt. 1, pp. 157*).—The food legislation enacted during the year ended July 1, 1903, in the United States and the insular possessions has been compiled.

The danger of keeping food products warm, F. Schardinger (*Wiener Klin. Wchnschr., 16 (1903), p. 468; abs. in Hyg. Rundschau, 14 (1904), No. 8, pp. 383, 384*).—Bacteriological studies showed that bad results may follow when food is kept warm for a considerable time.

Determination of effect of preservatives in foods on health and digestion, H. W. Wiley (*U. S. Dept. Agr. Yearbook 1903, pp. 289–302*).—Experiments extending over long periods have been carried on at the Bureau of Chemistry with healthy young men to study the effects of adding borax and boric acid to the diet. These are briefly described and some of the results are summarized as follows:

"The addition of small quantities of borax or boracic acid to the food of healthy subjects, even for a considerable period, extending in some cases to fifty days, produces a slight disturbance in the digestion and assimilation of the food.

"In larger quantities the effect produced upon different individuals varies. In some cases large quantities are tolerated with apparently little inconvenience, while in other cases, when the amount given daily reaches 2 or 3 gms., somewhat profound disturbances of normal conditions are developed. These disturbances are manifested by a feeling of depression and discomfort, attended very frequently by a dull and continued headache, with a sense of fullness in the head. In no instance, even when large doses were administered, did either borax or boracic acid produce any pronounced symptoms of diarrhea or diuresis.

"When pushed to the limit of toleration the quantities of the borax or boracic acid which produce nausea, vomiting, and loss of appetite vary greatly with the individual. In some cases these symptoms were produced by from 3 to 4 gms. daily, while in other instances these quantities could be tolerated.

"The elimination of the added borax or boracic acid is accomplished mostly through the kidneys. The merest traces of the ingested substances are found in the feces, and considerable quantities in the perspiration.

"The effect of the added preservatives upon the metabolic processes is of such a character as to be properly discussed only in connection with the analytical data relating thereto, and this discussion will be found in the proposed bulletin.

"By reason of the different degrees of susceptibility to the influences of these added substances manifested by different individuals, it is evident that it is impossible to foretell in any given case what effect may be expected. For this reason the protection of those more sensitive to the influences of these preservatives seems to be a wise and just measure. Hence, without concluding from this experiment that the use of boracic acid and borax in food products should be absolutely prohibited, it is evident that if they are employed proper notice of the fact should be given to the consumer, either on the labels of the packages or otherwise."

Cream as a farm product and a food, J. O. Peet (*Jour. British Dairy Farmers' Assoc., 17 (1902), pp. 17–26*).—Different methods of obtaining cream, its preservation, food value, and other topics are spoken of.

As pointed out by the author, "cream is a highly concentrated food, especially rich in fat, which is the most efficient of all food constituents in the production of heat and energy in the body of the consumer. Foods rich in fat are usually somewhat difficult of digestion, and are neither very agreeable to the majority of palates, nor easily retained by delicate stomachs. The fat of cream, however, like that of most dairy products, is easily digested, probably because of the very fine state of division in which it is present.

"Cream is also easily retained by the stomach, and is frequently given to patients suffering from diseases in which a light, nutritious, and easily retained diet forms an important part of the curative treatment. The proportion of fat is too high for it to be classed as a well-balanced food, and it is unsuitable for forming a large proportion of a diet; but it is a most nourishing and agreeable constituent of a mixed diet, and its use along with tea, fruit, and pastry is certainly increasing amongst the middle and the artisan classes."

Breakfast foods, C. E. Ellis (*Iowa Agr., 5 (1904), No. 1, pp. 19–21*).—A brief summary of a publication previously noted (E. S. R., 15, p. 884).

Paraguay tea, F. W. Neger and L. Vanino (*Der Paraguay-Thee. Stuttgart: F. Grub, 1903, pp. 56, figs. 22; rev. in Ztschr. Untersuch. Nahr. u. Genussmtl., 7 (1904), No. 10, p. 637*).—In this monograph the authors discuss the botany, culture, chemistry, and uses of Paraguay tea, and related questions.

Judging natural ice, M. Klostermann (*Ztschr. Untersuch. Nahr. u. Genussmtl., 7 (1904), No. 9, pp. 546–549*).—The need of caution in the use of ice is insisted upon,

owing to its possible contamination with micro-organisms, especially typhoid bacteria.

Investigation of canned-food products, P. SCHWEITZER (*Missouri Sta. Rpt. 1903, pp. 28–31*).—According to the author, "nearly every one of the thirty-eight brands of canned vegetables and fruits tested contained preserving agents. Sulphur dioxid or some bisulphite, and boracic acid or borax are the chemicals employed for the purpose, having superseded salicylic acid, formerly often employed, and formaldehyde, neither of which occurred in any one of the brands under examination. Without entering here into a discussion of their deleterious effects, they should as a matter of common equity not be employed in the preparation of any food substance, and are to be unequivocally condemned."

The presence of tin in large amounts was noted in some of the samples examined.

Concerning the sugar content of canned peas, F. SCHWARZ and F. RIECHEN (*Ztschr. Untersuch. Nahr. u. Genussmtl., 7 (1904), No. 9, pp. 550–553*).—Experimental data are reported.

Identification of sprats in preserved sardines and anchovies, M. HENSEVAL (*Trav. Sta. Recherches Pêche Maritime Ostende, 1903, p. 89; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 7 (1904), No. 9, p. 556*).—Differences in these fishes are pointed out which, in the author's opinion, render possible the identification of sprats in canned goods.

Smoking and canning sprats, M. HENSEVAL (*Trav. Sta. Recherches Pêche Maritime Ostende, 1903, pp. 60–66; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 7 (1904), No. 9, p. 555*).—Methods are described.

Concerning the value of meat extract and other artificial condiments, K. BEERWALD (*Ztschr. Diätet. u. Phys. Ther., 8 (1904), No. 2, pp. 111, 112*).—The value of meat extract as a stimulant to the flow of digestive juices and related topics are spoken of. In the author's opinion the yeast preparations, which are in some respects similar to meat extract, are much inferior to it.

Meat preservatives, A. REINSCH (*Ber. Untersuchungs. Altona, 1903, p. 7; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 7 (1904), No. 9, p. 555*).—The results of the examination of several preservatives are reported.

Chemistry of oysters (*Pharm. Jour., 4. ser., 16 (1903), p. 46; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 7 (1904), No. 9, p. 556*).—Proximate and ash analyses of oysters are reported. According to the author, the nutrients are largely present in a form in which they are readily assimilated. It is stated that one-half the crushed oyster and one-fourth of the whole oyster is soluble in water. The solubility in various alcoholic beverages is also spoken of.

The investigations on the nutrition of man which have been conducted in the United States under the direction of W. O. Atwater, R. TIGERSTEDT (*Hygiea, 65 (1903), pp. 376–408*).—The author summarizes and discusses the investigations on the nutrition of man which have been reported in bulletins of this Office.

Nutrition investigations at the Government Hospital for the Insane, Washington, D. C., W. O. ATWATER (*U. S. Dept. Agr., Office of Experiment Stations Rpt. 1903, pp. 503–512*).—A brief account is given of nutrition investigations which were carried on at the Government Hospital for the Insane. So far as can be judged from the results of these studies as compared with similar data obtained elsewhere, the dietetic management of the institution was very satisfactory.

The author reports that opportunities for improvement were observed, which, however, have to do with details rather than with the system as a whole; that the diet was varied and attractive and certainly abundant, but that on the whole the waste was larger than seems necessary, which would partially account for the fact that the cost of the diet was higher than would appear needful on theoretical grounds and higher than that of a similar diet in other institutions. He adds that, with the knowledge of theoretical requirements and existing conditions, it should be possible

to provide an entirely satisfactory diet without unnecessary waste, and thus materially reduce the cost. (See also E. S. R., 15, p. 703.)

Who is underfed? H. STERN (*New York Med. Jour. and Philadelphia Med. Jour., 79 (1904), pp. 811, 812; Dietet. and Hyg. Gaz., 20 (1904), No. 7, pp. 405-409*).—In connection with a discussion of food with special reference to underfeeding and overfeeding, the author considers the food requirements of normal individuals. In his opinion a normal individual may remain in good physical condition on a diet furnishing 30 to 35 calories of total energy or 23 to 28 calories of assimilable energy per day per kilogram of weight. He states that in his experience women have been found to require only a very little less energy than men.

Contribution to the metabolism of phosphorus, L. BÜCHMANN (*Ztschr. Diätet. u. Phys. Ther., 8 (1904), Nos. 2, pp. 67-74; 3, pp. 148-160*).—In experiments with 2 convalescent patients, in which egg yolk with and without added lecithin and edestin formed a part of the diet, the income and outgo of nitrogen, phosphorus, calcium, and magnesium were studied, as well as the digestibility of fat and carbohydrates.

The conclusion was drawn that lecithin must be regarded as very important in inducing gains of tissue containing phosphorus. The experiments did not furnish data for judging how much it surpassed other organic phosphorus compounds. Since it was so superior to edestin combined with inorganic phosphorus compounds in the experiments reported, it seemed clear in the author's opinion that inorganic phosphorus was all excreted. Whether or not this is always the case must be learned by further experiments. No relation between the excretion of nitrogen and phosphorus was noted.

The metabolism of phosphorus in the adult man, C. TIGERSTEDT (*Skand. Arch. Physiol., 16 (1904), No. 1-2, pp. 67-78*).—The author was himself the subject of experiments in which the metabolism of phosphorus was studied in a diet made up of starch, butter, sugar, etc., and practically free from phosphorus. The average amount in the feces was 0.134 gm. per day, a quantity which the author considers practically equal to the amount excreted through the intestines as a metabolic product.

The income and outgo of phosphorus was determined on a mixed diet, but no conclusion could be drawn as to the question whether increased consumption of this constituent results in retention rather than equilibrium. On a vegetarian diet the percentage amount of phosphorus excreted in the feces was greater than on a mixed diet. In these tests the balance of income and outgo of nitrogen was also reported and discussed. When the diet contained practically no nitrogen the average amount excreted in the feces was 0.65 gm. per day.

A metabolism experiment with vegetarians, W. CASPARI and K. GLAESSNER (*Ztschr. Diätet. u. Phys. Ther., 7 (1904), No. 9, pp. 475-485*).—On a strictly vegetarian diet one of the subjects, a man, digested 73.79 per cent protein and 88.49 per cent fat, the energy of the digested food being 91.11 per cent of that of the total food. Similar values for the other subject, a woman, were 75.79, 89.92, and 92.93 per cent. The balance of income and outgo of nitrogen was determined, as well as the different nitrogenous constituents of the urine.

The author points out that the physiological nutritive value of the vegetarian ration was about the same as in the case of a mixed diet, the greater loss of energy in the feces being offset by the smaller loss in the urine. Creatin was found in the urine, but no creatinin. The other constituents of the urine are briefly spoken of.

Review of agricultural investigations [on the nutrition of man], L. GRANDEAU (*Temps [Paris], 1904, May 7 and 21*).—Apropos of the organization of a new society in France in the interests of the hygiene of nutrition and the rational feeding of man, the author summarizes and discusses nutrition investigations which have been carried on in the United States, especially those conducted under the auspices of the Office of Experiment Stations.

Experiments on the behavior of iron in the human and animal body, H. LANDAU (*Ztschr. Klin. Med.* [*Berlin*], *46* (*1902*), *No. 1–4, pp. 223–283; abs. in Ztschr. Diätet. u. Phys. Ther.*, *7* (*1904*), *No. 9, pp. 514, 515*).—A large number of experiments led the author to conclude that inorganic iron salts were resorbed in the duodenum, though under ordinary physiological conditions the amount absorbed is very small. The form in which iron is stored and other related topics are discussed. Iron, it is stated, is largely excreted through the lower portion of the intestine, and only a very small amount through the kidneys.

The final products of the peptic digestion of protein, S. SALASKINE and Mme. E. F. KOVALOWSKAIA (*Zhur. Russ. Fiz. Khim. Obshch.*, *35* (*1903*), *pp. 421–424; abs. in Bul. Soc. Chim. Paris, 3. ser.*, *32* (*1904*), *No. 9, pp. 583, 584*).—The results obtained in the series of experiments reported confirm Hoppe-Seyler's belief that crystallizable bodies are formed from protein by the action of gastric juice.

Experiments on autodigestion in solutions of liver proteids, F. BOTTAZZI (*Bol. R. Accad. Med. Genova*, *18* (*1904*), *No. 3; abs. in Zentbl. Physiol.*, *18* (*1904*), *No. 4, pp. 98–100*).—The experiments were carried on with nucleo-proteids extracted from liver.

Concerning antialbumens, F. ROTARSKY (*Zhur. Russ. Fiz. Khim. Obshch.*, *35* (*1903*), *pp. 424, 425; abs. in Bul. Soc. Chim. Paris, 3. ser.*, *32* (*1904*), *No. 9, pp. 584, 585*).—Experiments are reported and discussed.

Mucin as a bacterial product, L. F. RETTGER (*Jour. Med. Research*, *10* (*1903*), *No. 1, pp. 101–108; reprinted in Studies Rockefeller Inst. Med. Research*, *1* (*1904*), *Art. 16*).—Mucin and an intermediate body, pseudomucin, were identified as products of bacterial action.

Concerning the connection between lability and activity of enzyms, O. LOEW (*Arch. Physiol.* [*Pflüger*], *102* (*1904*), *No. 1–2, pp. 95–110*).—In the author's opinion enzymic activity depends upon chemical or molecular lability, being very probably due to the presence of keton and amido groups. This lability of the atomic groups involves a condition of atomic motion which may be regarded as kinetic energy. This would be maintained by the free atmospheric heat and increased by artificial heat up to a certain point at which molecular rearrangement takes place. These and other theoretical considerations are discussed in the light of experimental evidence.

The regulation of heat by chemical means in man, J. E. JOHANSSON (*Skand. Arch. Physiol.*, *16* (*1904*), *No. 1–2, pp. 88–93*).—A controversial and polemical article. The author points out that man can endure a very low temperature without chemical heat regulation if the muscles are perfectly quiet. If the cooling is carried far enough the carbon-dioxid excretion increases; that is, a chemical heat regulation takes place.

Testing the Sondén-Tigerstedt respiration apparatus, TORA ROSENBERG (*Skand. Arch. Physiol.*, *16* (*1904*), *No. 1–2, pp. 79–87*).—The accuracy of the Sondén-Tigerstedt respiration apparatus was tested by burning a lamp in the respiration chamber, the conclusion being reached that the error due to the apparatus was only ± 0.76 gm. CO_2.

Concerning rye pollen and the poison in it which causes hay fever, KAMMANN (*Beitr. Chem. Physiol. u. Pathol.*, *5* (*1904*), *No. 7–8, pp. 346–354*).—The author studied the constituents of rye pollen and their properties, identifying an albumin as an active cause of hay fever. He recognized the fact that the pollen of other gramineæ and some other plants also possess similar toxic bodies.

ANIMAL PRODUCTION.

The chemical composition and feeding value of rice products, C. A. BROWNE, Jr. (*Louisiana Stas. Bul. 77, 2. ser., pp. 430–458, figs. 6*).—The results of microscopical studies of rice grain are reported, together with analyses of rice products and adulterated rice brans, and the results of artificial digestion experiments and of an

experiment with steers fed rice bran and rice polish. The digestion experiments with steers and some of the analyses have been noted from another publication (E. S. R., 15, p. 288), though in the present instance the data regarding the digestion experiments are more detailed.

The author points out the fact that rice hulls contain a high percentage of woody matter and insoluble silica, which has a detrimental effect on their feeding value, the sharp silica particles often causing irritation of the delicate membranes lining the digestive tract. The need of establishing a standard for rice bran is spoken of.

"Judging from the results of reliable analyses, rice bran should contain at least 12 per cent protein and 12 per cent fat, though an excessive amount of grits or broken rice might reduce these figures. In fixing a standard more stress should be laid, therefore, upon the maximum of fiber and ash. Rice bran exceeding 10 per cent fiber or 9 per cent ash should be regarded with suspicion. These limits are suggested, however, only tentatively, as the analyses of many samples from different mills are necessary before a standard can be fixed."

Rice bran and rice polish commonly contain grits or broken rice screenings in varying amounts. Judged by composition these grains have a high feeding value, but the author points out that many of the broken grains pass through the animal undigested.

"These fragments of rice are very hard to break up and are not easily affected by the digestive juices of the animal. Nearly 10 per cent of the dry matter in the excrement of an animal fed with polish consisted of undigested grits. If these grits could be ground up, or if they could be removed during milling, the digestibility of the feed would be increased."

Rice feeds are frequently found to be unpalatable owing to the development of rancidity. A number of determinations were made of the free fatty acids in oil from rice products. The amount reported varies from 6.9 per cent in oil from raw rice to 83.5 per cent in oil from very rancid rice bran. "The unheated bran turned very rancid; this change went on very slowly in the heated sample, and the slight increase observed was due probably to the natural oxidation which all oils and fats undergo on exposure to the air." The author recommends heating rice bran as a preventive of rancidity.

"If our millers could subject their bran as soon as it is made to a dry heat of 200 degrees Fahrenheit, or even higher, as is done sometimes in the kiln drying of various feeds, and then press the material into cake form, we believe all dangers of rancidity would be removed."

Another method for the prevention of rancidity which is proposed consists in the removal of a part of the oil. This the author believes would be advantageous as the percentage of fat is quite large and the oil would have a commercial value. Furthermore, the removal of the oil would perhaps counteract the laxative effects which have been noted when animals are fed large amounts of rice bran.

The milling of rice, feeding of rice products to farm animals, the fertilizing value of rice products, and other topics are also discussed.

The composition of Texas cotton-seed meal, H. H. Harrington and G. S. Fraps (*Texas Sta. Bul. 70, pp. 15, maps 2*).—The value of cotton-seed products is discussed, a list of Texas cotton-seed oil mills is given, and data regarding the composition of Texas cotton-seed meals reported.

"Of 46 samples of Texas meals tested, 33 contained over 7.5 per cent of nitrogen, while of 151 samples of meal examined in 9 other States only 8 contained over 7.5 per cent nitrogen.

"Texas cotton-seed meals on the average are richer in nitrogen than meal from other sections, and, therefore, should have a higher commercial value.

"The meals richest in nitrogen come from the western part of the State; those

lowest in nitrogen from the East, and the medium grades from the central cotton-growing region.

"There is very possibly a relation between the rainfall and the nitrogen content of cotton seed, the seed being richer in more arid sections. This difference may, however, be due to other causes."

Carob beans in the feeding of farm animals (*Rev. Gén. Agron.* [*Louvain*], *13* (*1904*), *No. 3, pp. 123–125*).—A summary of data on the feeding value of St. John's bread.

A summary of recent American work on feeding stuffs, C. F. LANGWORTHY (*U. S. Dept. Agr., Office of Experiment Stations Rpt. 1903, pp. 513–536*).—Data regarding investigations published in the United States during the last three and a half years, which have to do with the composition, digestibility, feeding value, adulteration, and sophistication of feeding stuffs, and related topics are summarized and discussed, with a view to showing the scope and extent of the work—particularly that carried on at the experiment stations.

Feeding-stuff inspection, C. D. WOODS and J. M. BARTLETT (*Maine Sta. Bul. 102, pp. 37–62*).—In carrying out the provisions of the State feeding-stuff law, 668 samples were analyzed, including cotton-seed meal, sugar and flaxseed meal, linseed meal, old and new process, gluten meal and feed, distillers' grains, a mixed feed containing distillers' grains, calf meal, molasses feed, animal meal, beef scrap, and similar products, poultry feeds, mixed and proprietary feeds, clover meal, bran, flour, and red-dog flour.

In general the feeding stuffs analyzed corresponded with the guaranteed composition. "The gluten feeds run considerably under the guaranteed percentage of protein. . . . The seasons of 1902 and 1903 were unfavorable to corn, and it may be that another season's goods may contain nearer 28 per cent protein. In compounding rations it will, however, probably be safer to discount this guarantee somewhat."

Commercial feeding stuffs sold in Maryland (*Maryland Agr. Col. Quart., 1904, No. 24, pp. 1–13*).—According to the provisions of the State feeding-stuff law analyses were made of a number of samples of Ajax flake, bran, corn-and-cob meal, cotton-seed meal, corn oil-cake meal, dried distillers' grains, gluten feed, hominy meal, linseed meal, malt sprouts, meat meal, middlings, red-dog flour, molasses feed, wheat screenings, calf meal, mixed and proprietary feeds, and poultry feeds.

Miscellaneous analyses, E. F. LADD (*North Dakota Sta. Rpt. 1903, pp. 33–35*).—Analyses are reported of wheat bran and shorts, stock food, prairie grasses, flax shive, and a commercial cattle feed. Some of the data reported follow:

Composition of prairie grasses and flax shive.

[Water-free basis.]

	Protein.	Fat.	Nitrogen-free extract.	Crude fiber.	Ash.
	P. ct.	*P. ct.*	*P. ct.*	*P. ct.*	*P. ct.*
Quack grass	16.12	4.50	44.01	25.93	9.41
Sand grass	9.06	2.13	50.22	33.46	5.13
Flax shive	5.62	3.46	39.08	47.47	4.37

Molasses as stock feed (*Demeter, 2* (*1904*), *No. 8, pp. 26, 27*).—The manufacture, feeding value, and importance of molasses feeds is briefly discussed. According to the author one of the chief requirements in molasses feeds is a satisfactory absorptive material. "One of the best that has been tried is finely ground bagasse." Its absorptive power is high, and "from it and molasses a food can be made that has 70 per cent of digestible carbohydrates."

Alfalfa and beef production in Argentina, F. W. BICKNELL (*U. S. Dept. Agr. Rpt. 77, pp. 32, pls. 6, figs. 5*).—Alfalfa growing and its relation to the cattle-raising

industry in Argentina are discussed and data summarized regarding the character of the cattle raised, export trade, profits received, and related topics. According to the author, "at the rate of one animal to 8½ acres, the usual average carrying capacity of native grasses, alfalfa makes land for grazing purposes worth five to eight times as much as it was before alfalfa took the place of the native grasses.

"The proposition to feed dry alfalfa and corn has applied only to steers for export alive, but it is bound to be applied also to those destined for chilled beef, for experience is gradually teaching Argentine beef producers that a grass or alfalfa fed steer can not compete with a corn-fed steer. The latter will be sounder, more solid, and his carcass will cut up to much better advantage. The corn-fed beef is worth more to the pound, because it is firmer and has less water in it than that of animals fattened on green alfalfa or grass only."

Alfalfa is fed both green and cured. The profits in raising this crop for hay and methods of stacking and marketing the hay are spoken of. Many of the cattle in Argentina are wild and difficult to handle. Dehorning, etc., are facilitated by the use of a long chute called a bréte, the construction of which is described.

Steer and lamb feeding, J. J. Vernon (*New Mexico Sta. Bul. 50, pp. 45, pls. 6*).—The present status of the cattle and sheep industry in New Mexico, the management of cattle ranges, and similar questions are discussed and experiments to determine the possibility of profitably fattening stock under existing conditions are reported. In the sheltered New Mexico valleys the climate is so mild that animals need no protection in winter except such as is afforded by a wind-break.

In the first test 3 lots of 3 steers, each weighing about 1,900 lbs., were fed for 192 days during the winter. On alfalfa hay alone the steers made an average daily gain of 1.36 lbs. per head; those fed alfalfa hay and shredded Kafir-corn stover, 1.49 lbs., and those fed alfalfa hay and shredded corn stover, 1.16 lbs. The feed required per pound of gain was 17.82 lbs. on alfalfa hay alone, and the cost of a pound of gain 6.24 cts. Similar values for the Kafir-corn stover ration were 15.23 lbs. and 5.18 cts., and for the corn-stover ration 17.93 lbs. and 6.17 cts. The dressed weight was greatest with the alfalfa lot, 53.24 per cent, and least with the corn-stover lot, 51.3 per cent.

The second test was made with 4 lots of 8 steers each and covered 76 days in the winter. All the steers were fed alfalfa hay, lot 1 receiving in addition about one-third of a ration of corn, lot 2 a full ration of corn, and lot 3 about one-third of a ration of wheat, and bran 3:1. The average daily gain ranged from 1.22 lbs. per head with lot 1 (alfalfa and a limited corn ration) to 1.62 lbs. with lot 3 (alfalfa and mixed grain). In the case of the latter lot the smallest amount of feed, 12.09 lbs., was required per pound of gain, and the greatest quantity, 16.27 lbs., was noted with the former lot. The cost of feed per pound of gain ranged from 4.3 cts. with the steers fed alfalfa only to 6.59 cts. with those fed alfalfa and a limited corn ration. The dressed weight averaged about 51 per cent of the live weight in every case.

In a test with lambs 30 animals, weighing about 45 lbs. each, were divided into 3 uniform lots. In the 128 days of the test the lambs fed alfalfa hay alone made an average daily gain of 0.185 lb.; those fed alfalfa hay, shredded Kafir-corn stover, shredded corn stover, and corn, 0.233 lb., and those fed alfalfa hay, shredded Kafir-corn stover, and shredded corn stover, 0.144 lb., the cost of a pound of gain in the 3 cases being 4.15, 5.27, and 4.33 cts. The feed required per pound of gain ranged from 9.166 lbs. with lot 2 (fed grain) to 13.716 lbs. with lot 3 (alfalfa hay and stover without grain). The smallest dressed weight, 47.34 per cent, was noted with the latter lot, and the greatest, 54.31 per cent, with the former.

Among the conclusions drawn were the following:

"The results of these experiments indicate that feeding steers and lambs for the local markets will prove remunerative so long as dealers will pay the same price for the home-fed product that they must pay for the imported article of equal quality.

"Beef and mutton, of a quality suitable for the local market demands, can be produced by feeding alfalfa hay alone. In these tests the addition of grain, though rather high in price, showed the following advantages over feeding alfalfa hay alone: The return per ton for the alfalfa hay consumed was greater, more rapid gains were made, the feeding period was shorter, and a much better product was secured.

"The lambs in these experiments gave a greater return per ton for the alfalfa hay fed than did the steers.

"About one hundred days for lambs and five or six months for steers is a sufficient time in which to fit them for the local markets when fed on alfalfa hay alone. It will require less time when grain is fed with the alfalfa hay.

"Frequent weighing, because of the unavoidable excitement, is probably not conducive to rapid gains with range-grown steers."

Summer ranges of eastern Nevada sheep, P. B. KENNEDY (*Nevada Sta. Bul. 55, pp. 53, pls. 31*).—The grazing region studied lies in Eureka and Elko counties. Special attention was paid to the plants eaten, injury to plants by grazing and trampling, and methods of handling sheep. The principal forage plants were collected for identification and analysis.

In the author's opinion "there is plenty of forage for sheep at the present time on the eastern Nevada ranges.

"Grasses and grass-like plants are eaten to a very small extent by sheep during the summer, while cattle feed almost entirely on grasses. The forage for sheep during the summer consists for the most part of sunflowers, daisies, leaves of different shrubs, and many other plants commonly spoken of as 'weeds.'

"The plants which appear to have suffered most in this region are those of a shrubby nature, such as the Indian currant or snowberry, wild currants, rosebushes, service berry, and chokecherry. The sheep are responsible for the most part for the total destruction of numerous Indian currant, wild currant, and rosebushes. They eat them extensively during the fall months, feeding on the leaves and tender young shoots until finally the main stems die and a bunch of dry sticks remains. Cattle, however, are exceedingly destructive to the service berry and chokecherry.

"At the present time many of the ranges are better adapted for the raising of sheep than for cattle. This can be accounted for by the fact that the grasses which were once so abundant have been grazed on to an injurious extent by cattle and have not been allowed to produce seed, while the 'weeds' have been left untouched and have increased.

"The fact that water is frequently scarce in the late summer months has prevented the ranges from being overstocked by sheep."

The author discusses the problem of the control of sheep and cattle ranges and the need of studies of the feeding value of forage plants now growing on the ranges with a view to devising measures for restoring those which have been overstocked and keeping them in good condition.

Some of the plants found on the ranges are commonly regarded as poisonous, one of the principal ones being the poison camas (*Zygadenus paniculatus*), which is sometimes called poison sego lily or lobelia. So far as the author could learn no serious loss occurs from stock eating this plant in the spring, and he considers it probable that the large number of ewes and lambs lost at this time die from maternal or other causes.

Cape v. Turkey mohair, S. B. HOLLINGS (*Agr. Jour. Cape Good Hope, 24 (1904), No. 5, pp. 561–566, figs. 4*).—In an article quoted from the *Midland News* a number of different samples of mohair from the Cape of Good Hope and from Turkey are described.

Pig farming and bacon curing, W. FRANK (*Agr. Jour. Cape Good Hope, 24 (1904), Nos. 2, p. 243; 3, pp. 335, 336; 5, pp. 574, 575*).—A summary of available information with special reference to the requirements of local pig raisers.

The construction of pigsties (*Jour. Bd. Agr.* [*London*], *11* (*1904*), *No. 3, pp. 129–135*).—Directions are given for the construction of improved pigsties.

The artificial hatching of chickens (*Jour. Bd. Agr.* [*London*], *11* (*1904*), *No. 3, pp. 135–143, fig. 1*).—Tests of the artificial hatching of chickens carried on at the poultry farm of the college at Reading are reported. During the year 3,674 fertile eggs have been tested with 13 incubators and from these 2,572 chickens and ducklings were hatched. The incubators were kept in a specially constructed incubator house having provisions for satisfactory ventilation.

"The results of these observations prove that hatching houses can be successfully employed on a larger scale than has hitherto been thought desirable, and that a percentage of hatching may be obtained of more than 70, even where the operators have not had much experience. But to secure this result the conditions must be favorable, more especially in respect to ventilation."

The rearing and management of chickens (*Jour. Dept. Agr. and Tech. Instr. Ireland, 4* (*1904*), *No. 4, pp. 672–676, figs. 2*).—A general discussion of the subject. The article has also been reprinted as one of the Department of Agriculture and Technical Instruction for Ireland leaflets (No. 43).

Cooperative poultry societies in Ireland, H. de Courcy (*Jour. Bd. Agr.* [*London*], *11* (*1904*), *No. 2, pp. 80–95, figs. 5*).—It is stated that the poultry industry in Ireland has been very much helped by the work of a number of societies and the present article describes the methods followed by one of them, the Irish Agricultural Organization Society.

Cooperation, according to the author, "has already taught the farmers and cotters to place on the markets produce which, in freshness, cleanliness, quality, and general mode of treatment, is on a level with the best produce of other countries, and it has proved by demonstration that it is not quantity but quality which pleases customers, retains their custom, and produces most money."

DAIRY FARMING—DAIRYING.

The college dairy herd, H. H. Dean (*Ontario Dairymen's Assocs. Rpts. 1903, pp. 155–161*).—Individual differences in the cows of the Ontario Agricultural College herd are pointed out and the improvement of dairy herds in general is discussed.

Some experiments on the passage of odoriferous and coloring substances into milk, Dombrowsky (*Arch. Hyg., 50* (*1904*), *No. 2, pp. 183–191*).—Various substances were fed to a goat. Anise and fennel seeds, and also garlic were readily eaten, the odor of these materials passing into the milk. Garlic produced not only the characteristic odor of this substance, but also a very disagreeable taste which persisted for a long time, even after heating and cooling.

The odor of anise and fennel was not disagreeable nor very strong, and was removed by heating. A change in the color of the milk was produced by carrots and chrysophanic acid, but the alteration was not marked. Alizarin produced a coloration only when given with alkalis. There is believed to be practically no danger of food causing marked modification in the color of milk. Slight changes in the odor are produced more easily.

The absorption of odors by milk was also studied. The odors of iodoform and anise oil were taken up readily and held for a long time. The odor of carbolic acid was taken up quickly, but readily lost. This is also true of turpentine and formalin. The odor of chlorid of lime was only feebly absorbed.

The composition of milk, H. D. Richmond (*Analyst, 29* (*1904*), *No. 339, pp. 180–189*).—The average composition of 15,313 samples of milk analyzed during 1903 was as follows: Specific gravity 1.0322, total solids 12.78 per cent, fat 3.83 per cent, and solids-not-fat 8.95 per cent. The average fat content of the morning milk was 3.62 per cent, and of the evening milk 4.05 per cent. The average interval between the

morning and evening milkings was 10.8 hours, and between the evening and morning milkings 13.2 hours.

Analyses of this character have been made at the same laboratory for a series of years and the results have sometimes been quoted as representing the average composition of milk in England. As this, however, has sometimes been disputed, the author considers the possibility of the samples analyzed being of exceptional quality. Milk coming from farms located on cretaceous formations showed a slightly higher percentage of fat than the milk from farms located on sandstone and clay formations, but the difference is not believed to be marked enough to permit of any sweeping assertions. The difference in the intervals between milkings, noted above, is also referred to as a cause of some samples being low in fat.

The author also discusses the views of Storch concerning the existence of a mucoid membrane surrounding fat globules, and concludes that the theory must be considered as disproved.

Contribution to the study of slowly creaming milks, L. MARCAS (*Rev. Gén. Lait, 3 (1904), No. 16, pp. 361–368*).—Samples of slowly creaming milk allowed to separate spontaneously in the separator and also subjected to centrifugal separation, left in both cases more fat in the skim milk than did ordinary milk. As a general thing, the samples of slowly creaming milk examined were richer in fat, total solids, and ash than the average milk furnished the dairy at which the investigations were made. Of the constituents in the ash, phosphoric acid and lime especially were increased.

On the breaking up of globules of fat in milk, C. BARTHEL (*Rev. Gén. Lait, 3 (1904), No. 19, pp. 434–440*).—Milk subjected to strong mechanical action has been reported to cream less perfectly and to give much greater differences between the Adams and Gottlieb methods of analysis than the same milk not subjected to such agitation.

The author believes that this difference is due to the breaking up of the fat globules into still finer globules, and in this article reports countings of the number of globules, both before and after churning for different periods ranging from 5 to 90 minutes. The number of globules increased in some instances from about 3 million to 11 million per cubic centimeter. Determinations of the percentage of fat by the Adams method showed a corresponding decrease, while the percentage determined by the Gottlieb method remained practically constant.

It is believed that the Gottlieb method might well be adopted universally as a standard method for the determination of fat in milk.

Investigations on the membrane surrounding fat globules in milk, W. VÖLTZ (*Arch. Physiol.* [*Pflüger*], *102 (1904), No. 8–9, pp. 373–414*).—Chemical investigations extending over a series of years are reported in detail, from which the author concludes that the fat globules possess a firm membrane containing nitrogenous and nonnitrogenous organic compounds, lime, phosphoric acid, magnesia, and sulphur, the proportions of the different constituents varying greatly in the different kinds of milk under investigation.

The proportion of nitrogen to ash ranged from 1:0.09 to 1:14.7; the proportion of organic substances to ash, 1:0.01 to 1:0.86; nitrogen to phosphorus, 100:0.15 to 100:15.5; and ash to phosphoric acid, 100:0.34 to 100:48.43. The author also reports staining the membrane with carbol-fuchsin. The individual globules showed great variation in the intensity with which the membrane was stained. The membrane did not appear to be homogeneous, and at times appeared in the form of a network.

On the origin of lactose, C. PORCHER (*Compt. Rend. Acad. Sci. Paris, 138 (1904), No. 13, pp. 833–836*).—In order to determine whether lactose is formed in the animal body before reaching the mammary gland or is formed in the gland itself, the author removed the mammary glands of 2 goats and examined the urine before and after parturition.

In neither case was sugar present in the urine before parturition, but it was present in large quantities, mainly in the form of glucose, after parturition. A slight amount of lactose found in the urine was attributed to the incomplete removal of the glandular tissue. The author therefore concludes that normally the glucose is transformed into lactose in the mammary gland.

On the origin of lactose, C. PORCHER and COMMANDEUR (*Compt. Rend. Acad. Sci. Paris, 138 (1904), No. 14, pp. 862–865*).—A study of the urine of a pregnant woman suffering with diabetes confirmed the author's conclusions, noted above, that normally lactose is produced from glucose in the mammary gland.

On the origin of lactose, C. PORCHER (*Compt. Rend. Acad. Sci. Paris, 138 (1904), No. 15, pp. 924–926*).—Observations were made on cows affected with milk fever, the results of which, along with those obtained in previous studies, are believed to establish thoroughly the rôle of the mammary gland in forming milk sugar from glucose brought to it from the blood.

On the decrease in the citric-acid content of milk due to heating, G. OBERMAIER (*Arch. Hyg., 50 (1904), No. 1, pp. 52–65*).—The fact that symptoms of infantile scurvy often appear in infants fed sterilized milk, and the fact also that such symptoms tend to disappear by the feeding of uncooked milk or the administration of fruit juices containing citric acid, led the author to make determinations of citric acid in milk subjected to heating at different temperatures for varying lengths of time.

In general, heating was found to produce a notable diminution in the percentage of citric acid which, according to different observers, is normally from 0.18 to 0.25 per cent. Heating for 10 minutes on an open fire caused a diminution of about 15 per cent of the total amount present. The explanation is offered for this change that the citric acid exists normally in milk in the form of an acid salt, calcium bicitrate, and is transformed by oxidation during heating into calcium tricitrate, which is only slightly soluble. Heating at 80° C. produced a much smaller change in the content of citric acid, and in this respect pasteurization at that temperature is better than sterilization at 100°.

Influence of aeration on lactic fermentation, C. BARTHEL (*Rev. Gén. Lait, 3 (1904), No. 13, pp. 294–301*).—Experimental work is reported, from which the conclusions are drawn that aeration retards fermentation in milk due to bacteria belonging to the lactic-acid group, and that the retardation caused by aeration is still further increased by the lowering of the temperature.

Experimental investigations on the preservation of milk, C. NICOLLE and E. DUCLOUX (*Rev. Hyg. et Police Sanit., 26 (1904), No. 2; abs. in Bul. Inst. Pasteur, 2 (1904), No. 11, p. 504*).—Milk kept at 5° C. for 24 hours showed at the end of that time 10,800 bacteria per cubic centimeter, while milk kept at 14° showed 5,820,000 bacteria, showing the benefit of refrigeration in reducing the number of bacteria.

Tests were also made of hydrogen peroxid as a means of preserving milk. Hydrogen peroxid was added to milk to the extent of 1 to 2 per cent, and the samples were then kept at temperatures of 15, 22, and 34°. In the samples treated with hydrogen peroxid the number of bacteria diminished during the first 10 hours, following which the number of bacteria gradually increased, but did not in any case equal the number in the control samples. No trace of the antiseptic was found in the milk after several hours.

While the use of hydrogen peroxid has an advantage over pasteurization in not altering the constitution of the milk, it does not destroy the pathogenic bacteria.

On pasteurized milk, N. SWELLENGREBEL (*Centbl. Bakt. u. Par., 2. Abt., 12 (1904), No. 11–16, pp. 440–448*).—Bacteriological examinations of pasteurized milk sold in hermetically sealed bottles in Amsterdam showed a wide variation in the bacterial content. The lowest number per cubic centimeter found was 290, and the highest 49,875. Other causes than the temperature of pasteurization were believed to influence these results.

Four such possible causes were studied, namely, the rubber band used in sealing the bottles, the dried milk on the inner surface of bottles not thoroughly cleansed, the formation of a membrane on the surface of the milk during heating, and the production of foam by the agitation of the milk. The use of perfect rubber bands and the thorough cleansing of the bottles were instrumental in lessening the bacterial content. In order to prevent the formation of a surface membrane and foam, it is believed to be better to heat the milk for a longer period at 60 to 65° C.

It is noted that while strong agitation prevents the formation of the surface membrane, it favors the production of foam and is, therefore, not to be recommended.

Utilization of milk as food, A. BONN (*Rev. Gén. Lait, 3 (1904), Nos. 16, pp. 368–372; 17, pp. 396–400*).—This is a brief résumé of legislation and regulations concerning the sale of milk in Germany, England, Belgium, Denmark, France, Italy, Switzerland, and the United States.

On the isolation of a ferment-producing enzym in cow's milk and human milk, J. STOKLASA (*Arch. Hyg., 50 (1904), No. 2, pp. 165–181*).—The author describes the isolation of a new enzym in milk having the power of fermenting lactose. The method employed in the isolation of this enzym is described in detail.

Milk powder prepared at the cooperative dairy of Oostcamp, C. HUYGE (*Rev. Gén. Lait, 3 (1904), Nos. 14, pp. 320–325, fig. 1; 17, pp. 400–402*).—Notes are given on the preparation and properties of this material, and several analyses are reported. The powder prepared from whole milk contained 3.62 per cent of water, 5.67 per cent ash, 26.75 per cent fat, 32.86 per cent casein, and 31.10 per cent of lactose.

Waste waters from dairies, F. SCHOOFS (*Rev. Gén. Lait, 3 (1904), Nos. 14, pp. 313–319; 15, pp. 344–352*).—This gives data concerning the quantity of water used in creameries, and reports results of chemical and bacteriological studies of the waste water.

The farm separator: Its relation to the creamery and to the creamery patron, E. H. WEBSTER (*U. S. Dept. Agr., Bureau of Animal Industry Bul. 59, pp. 47*).—Introductory notes are given on dairying in the West, following which the author points out the advantages derived from the use of the cream separator on the farm, discusses rather fully the proper care and management of the separator, describes the most approved methods for the management of cream on the farm, reports investigations made in Kansas during 1903, and in conclusion presents a system of cream grading which was recommended by the author and adopted by a creamery company in Kansas. The subject is discussed first from the standpoint of the dairyman, and, secondly, from the standpoint of the creamery. It is distinctly stated that the subject is treated wholly from the standpoint of western practice.

The experimental work reported in the bulletin was performed by the author at Colby, and by C. E. Gray in Topeka. During the period from July 20 to August 1, 68 patrons delivered cream at the receiving station at Colby, where an acid test was made of every can received. The data obtained are tabulated. The acidity of the milking of the morning on which delivery was made averaged 9.3, as determined by Mann's acid test; of the evening before, 22.1, and of the morning before, 29.5. From 30 to 50 per cent of the cream received each day was sweet.

Maximum and minimum temperatures at Colby during the period are reported, and the conclusion is drawn that the factor of temperature has considerable influence on the acidity of the cream. When the deliveries were made on alternate days only a few patrons delivered sweet cream, and these were provided with means for cooling the cream quickly and keeping it cool until delivered. Many other facts were brought out, such as the irregular methods followed in the delivery of cream, variations in the size of the cans used, etc.

Part of the cream received at the Colby station was pasteurized, and all of it was shipped to a creamery in Topeka, where observations were made on the temperature, acidity, and condition of the cream. Cream showing an average acid test of 10.21

when pasteurized was found on arrival at destination, 24 hours later, to have increased in acidity to 16.14. Pasteurized cream 2 days in transit showed an acid test of 12.28 before shipment and 30.88 after. The corresponding figures for unpasteurized cream, 1 day on the road, were 21 and 33.8; and 2 days on the road, 26.5 and 38.5.

The cream was also graded before and after shipment, according to the system devised by the author. Detailed data are given in tabular form relative to the shipments of both the pasteurized and unpasteurized cream. Several conclusions are drawn from the results obtained. "One important deduction from this work is that it does not pay to pasteurize sour cream at the shipping station."

The system of grading cream, devised by the author, is based upon the acid test as giving a very fair indication of the quality of the cream. In the creamery adopting this system the dividing line between grades 1 and 2 was made at 15 by Mann's acid test. Detailed instructions for making this test by the use of alkaline tablets are given in the bulletin. It is believed that this system of grading cream will go a long way toward making a line of demarcation between good and bad cream.

Recent investigations regarding the factors that control water content in butter, F. T. Shutt (*Ontario Dairymen's Assocs. Rpts. 1903, pp. 80–86*).—This is a brief summary of investigations relating to the factors affecting the percentages of water and salt in butter, details of which are to appear soon in bulletin form. Some of the results regarding the water content may be noted as follows: The higher the churning temperature within reasonable limits the higher the water content. The high temperature of wash water also tended to a high moisture content, and vice versa.

It was found that a high churning temperature could not be sufficiently corrected by using cold wash water. The larger the granules the more water the butter contained. The water content was not affected by allowing the butter to drip from 10 to 30 minutes after washing. Unsalted butter contained slightly more water than salted butter. Working slightly before salting did not materially affect the water content. Increasing the period between salting and working reduced the percentage of water.

Some of the factors affecting the salt content of butter were as follows: Decreasing the temperature of the wash water lessened the salt content of the butter. The larger the granules the higher the percentage of salt. The heavier the salting the more salt was retained in the finished product. An interval of 24 hours between salting and working decreased the salt content as compared with salting after 24 hours and working at once.

On the causes of the changes occurring in canned butter, L. A. Rogers (*Centbl. Bakt. u. Par., 2. Abt., 12 (1904), Nos. 11–16, pp. 388–396; 19–21, pp. 597–602*).—This is an account of investigations also published in another form as Bulletin 57 of the Bureau of Animal Industry (E. S. R., 15, p. 1116).

Contribution to the study of the butters of the Vendée, P. Touchard and L. Bonnétat (*Bul. Mens. Off. Renseignements Agr., 3 (1904), Apr., pp. 433, 434*).—Analyses are reported of several samples of butter made from cream which had been separated by slowly heating the milk at a temperature of 80 to 85° C. for 3 or 4 hours. The fat content of the butter was low, ranging from 76.8 to 82.5 per cent; while the casein was proportionately increased. The butter has poor keeping qualties.

On the physical constitution of butter, M. Beau (*Rev. Gén. Lait, 3 (1904), Nos. 10, pp. 224–228, figs. 3; 11, pp. 247–252*).—Physical studies of samples of butter designated opaque, clear, and mottled are reported

Note on some physical constants obtained with margarin, E. Russell and V. H. Kirkham (*Analyst, 29 (1904), No. 340, pp. 206–208*).—Considerable variation in the composition of margarin is believed to be demonstrated by the analytical data for 15 samples which are reported.

Export butter, J. W. MITCHELL (*Ontario Dairymen's Assocs. Rpts. 1903, pp. 174–182*).—Some of the requisites of butter for export are briefly stated, and the manufacture of such butter is discussed.

Studies on whey butter, G. FASCETTI (*Rev. Gén. Lait, 3 (1904), No. 18, pp. 409–416*).—In some of the cheese factories in Italy butter is made from the fatty material (brèches) obtained from whey by acidification and heating at 75 to 80° C. The butter made from this fat is of inferior quality and is sometimes used to adulterate butter made from cream. The author's method of detecting such butter, either alone or in mixtures, depends upon the staining of the albuminous material associated with the fat globules. An alcoholic solution of rocellin, obtained from the lichen *Rocella tinctoria*, was found suitable for this purpose. A small quantity of the coloring material in solution is incorporated with the butter and the mixture is examined under a microscope, butter made from cream showing no coloration, while samples containing "brèches" butter are more or less extensively colored, depending upon the quantity present.

On some constituents of Emmenthaler cheese, E. WINTERSTEIN (*Ztschr. Physiol. Chem., 41 (1904), No. 6, pp. 485–504*).—This is in continuation of investigations previously reported (E. S. R., 14, p. 696).

The author finds in Emmenthaler cheese a series of nitrogenous products which may be looked upon as primary cleavage products of the proteids of the fresh cheese. These are glycocoll, alanin, amido-valeric acid, leucin, carbo-pyrrolic acid, aspartic acid, glutaminic acid, tryptophane, histidin, and lysin. Oxyamido acids are also probably present. The amounts of the different cleavage products were not constant. In addition to the substances named simpler products were found, as follows: Tetramethylenediamin, guanidin, pentamethylenediamin, and ammonia.

It is believed that tetramethylenediamin and guanidin are derived from arginin, and pentamethylenediamin from lysin, and that this change is brought about by the bacteria present in cheese. In addition to the crystalline cleavage products, peptones are also present, of which two are described. In the ripened cheese, moreover, nuclein bases and cholin were also found. The nitrogen-free constituents include succinic acid, citric acid, and also lactic acid.

The present status of the question of cheese ripening, W. WINKLER (*Centbl. Bakt. u. Par., 2. Abt., 12 (1904), Nos. 4–5, pp. 97–105; 9–10, pp. 273–289*).—The literature relating to the ripening of hard cheese is critically reviewed, a bibliography being appended to the article.

On the importance of strictly anærobic butyric-acid bacteria in the ripening of hard cheese, A. RODELLA (*Centbl. Bakt. u. Par., 2. Abt., 12 (1904), No. 1–3, pp. 82–89*).—This is a discussion of this subject based, to a large extent, upon recently published work of the author. Such bacteria are believed to play an important part in the ripening process.

On the distribution of the bacteria in Grana cheese, C. GORINI (*Centbl. Bakt. u. Par., 2. Abt., 12 (1904), No. 1–3, pp. 78–81, pl. 1; Rev. Gén. Lait, 3 (1904), No. 13, pp. 289–293, pl. 1*).—It was found that in this Italian cheese the bacteria were in part uniformly distributed throughout the mass, and in part aggregated in colonies of different sizes which were irregularly distributed. This irregular distribution of the bacteria serves to increase the causes of error in quantitative bacteriological examination.

On the swelling of Edam cheese, F. W. J. BOEKHOUT and J. J. OTT DE VRIES (*Centbl. Bakt. u. Par., 2. Abt., 12 (1904), No. 1–3, pp. 89–93, pl. 1*).—A short thick bacillus growing readily on gelatin was obtained in a cheese factory, where the production of gassy cheese had long been a source of trouble, and used in experiments to determine the nature of this trouble.

Whey gelatin was inoculated with this micro-organism and the gas collected and analyzed. In 11 experiments from 27.7 to 52.8 cc. of gas was obtained from 160 cc.

of whey. The proportion of oxygen to carbon dioxid in this gas varied from 1 :2.51 to 1 : 1.45. Only a portion of the sugar in the whey was found to take part in the formation of these gases. In further experiments it was found that this micro-organism would not grow in the presence of over 0.3 per cent of lactic acid. It has been found possible in practice to lessen the production of gas by the addition of potassium nitrate. This was found experimentally to be converted into potassium nitrite, which was finally also decomposed. Sodium or potassium chlorate used in place of the potassium nitrite were also reduced in a similar manner.

In the production of gas where the atmospheric oxygen is excluded and the free oxygen contained in the cheese is soon used up, this micro-organism apparently decomposes the milk sugar; but when a more available source of oxygen, such as potassium nitrate, is present, this substance is apparently utilized first. When the added potassium nitrate was insufficient the milk sugar was also attacked. The addition, therefore, of potassium nitrate furnishes the micro-organism with oxygen in a more readily assimilable form than the oxygen of milk sugar, and also favors the transformation of milk sugar into lactic acid, which tends to check the growth of the gas-producing micro-organism.

On a slime-producing organism belonging to the Bacterium güntheri group, and the serious trouble caused by it in an Emmanthaler cheese factory, R. BURRI (*Centbl. Bakt. u. Par., 2. Abt., 12 (1904), Nos. 6-8, pp. 192-204; 11-16, pp. 371-388*).—In a cheese factory in Switzerland considerable trouble was experienced by the whey in the cheese becoming ropy within 8 to 12 hours after the cheese was put in the press. Such cheese was very much injured in appearance and tended to decompose early.

The investigation of this trouble by the author showed the causal agent to be a micro-organism not previously described, but resembling in its morphological and cultural characteristics *Bacterium guntheri*. This micro-organism produced ropiness in milk at a temperature of 37 to 40° C., and also brought about corresponding changes in cheese made from inoculated milk. The whey in such cheese was expressed only with great difficulty. The micro-organism was found in fresh milk obtained with great precautions to prevent infection.

It is therefore believed that the micro-organism was present in the udder. It was not found outside of milk and cheese. The changes brought about in milk by this micro-organism are similar to those previously described by other authors.

The preservation and safe transportation of butter and cheese, J. A. RUDDICK (*Ontario Dairymen's Assocs. Rpts. 1903, pp. 141-151, 170, 171*).—This is a general discussion of this subject, in which experimental data are reported on the loss in weight of cheese during curing, and also as affected by coating with paraffin.

The international dairy federation and international dairy congresses (*U. S. Dept. Agr., Bureau of Animal Industry Circ. 46, pp. 14*).—This contains an account of the First International Dairy Congress, held at Brussels in September, 1903, and information concerning the second congress, which it is proposed to hold at Paris in 1905. The United States was represented on the permanent international dairy committee by the late H. E. Alvord, of this Department.

A provisional committee for the United States has been appointed for the purpose of arousing an interest in the international dairy movement, and an effort is being made to have the dairy interests of the United States fully represented in the International Dairy Congress and International Dairy Exposition to be held at Paris in October, 1905.

The dairy situation, W. D. HOARD (*Ann. Rpt. New Jersey State Bd. Agr., 31 (1903), pp. 289-310*).—Needed changes in dairy methods are pointed out in this address.

Dairy management in New Jersey, E. B. VOORHEES (*Ann. Rpt. New Jersey State Bd. Agr., 31 (1903), pp. 263-287*).—This is a general discussion of this subject, includ-

ing considerable statistical matter and results of experiments at the New Jersey Station.

Report of the dairy institute at Proskau, 1904 (*Ber. Tät. Milchw. Inst. Proskau, 1904, pp. 22*).—This is a general review of the work of the institute during the year ended April 1, 1904.

Annual reports of the dairymen's associations of the Province of Ontario, 1903 (*Ontario Dairymen's Assocs. Rpts. 1903, pp. 190*).—Among the papers presented at the meetings of the associations of Western and Eastern Ontario, and published here in full, are the following: Chemical Notes for 1903, by W. P. Gamble; Cleanliness and Sanitary Conditions of Factories, by W. G. Medd; Bacteriological Notes on Butter, by F. C. Harrison; The Use of Acidimeter, by F. Herns; Judging Cheese, by R. M. Ballantyne; Defects of Canadian Butter, by P. W. McLagan; The Best Methods of Caring for, Delivering, and Determining the Value of Cream, by J. A. McFeeters; Managing a Herd for Profit, by Adda F. Howie; The Cooling of Curing Rooms, by W. A. Bothwell; Ripening Cream, Churning, and Packing Creamery Butter, by J. C. Bell; The Requirements of the Export Butter Trade, by A. Smith; Experiments in Ripening Cheese at Various Temperatures, by H. H. Dean; The Selection, Care, and Feed of the Dairy Cow, by H. Glendinning; Hints on Ventilation, by J. A. Ruddick; Footprints in the March of Modern Dairying, by T. McGillicuddy; Dairy Instruction at the Agricultural College, by H. H. Dean, and The Transportation of Dairy Products, by J. A. Ruddick. Other articles not included in the above list are noted above.

VETERINARY SCIENCE AND PRACTICE.

Alexins and bactericidal substances of normal serum, Y. PIRENNE (*Centbl. Bakt. u. Par., 1. Abt., Orig., 36 (1904), Nos. 2, pp. 256–266; 3, pp. 388–397*).—The present investigations were undertaken for the purpose of determining the bactericidal action of rat serum toward anthrax and other organisms, and also whether such action was due to one specific substance or to several causes. It was found that *Bacillus mesentericus*, *B. subtilis*, *B. megatherium*, and *B. mycoides* were as quickly destroyed by rat serum as was *B. anthracis*.

Notes are also given on the effect of heating rat serum, agglutination caused by the serum, filtration, and neutralization of the serum. Normal rat serum possesses, even after heating to 56° C., a bactericidal action of bacilli of the anthrax group. This action is apparently not due to alexins, immune bodies, or agglutinins. In general, however, the bactericidal power of sera is of special importance when it results from the combined action of an alexin and an immune body.

Bacterial hemolysins and antihemolysins, R. KRAUS and B. LIPSCHÜTZ (*Ztschr. Hyg. u. Infectionskrank., 46 (1904), No. 1, pp. 49–67*).—The authors carried on experiments with tetanolysin, staphylolysin, and vibriolysin. The amount of lysin required to dissolve 5 cc. defibrinated rabbit's blood in 0.85 per cent salt solution within 4 hours, at a temperature of 37° C., was taken as the hemolytic dose.

By adding an appropriate quantity of antihemolysin it was found possible to protect red blood corpuscles against the action of the hemolysin. The greater the toxicity of the lysin, the more rapid its injury to the cells, and the greater its affinity for the blood cells the more antihemolysin is required to neutralize it. Comparative experiments with normal and immune antihemolysins showed that these differ only in the intensity of their action and not in their essential nature.

The influence of the stromata and liquid of laked corpuscles on the production of hemolysins and agglutinins, G. N. STEWART (*Amer. Jour. Physiol., 11 (1904), No. 3, pp. 250–281*).—Rabbits and guinea pigs were used as experimental animals in these investigations. It was found that the stromata and hemoglobin-containing liquid of blood corpuscles, after laking by the use of reagents, stimulate

the production of specific hemolytic and agglutinating substances when injected into animals of another species. Blood corpuscles fixed by formaldehyde cause the production of agglutinins and hemolysins and are in turn susceptible to agglutination by specific sera.

Normal agglutinins, R. SCHELLER (*Centbl. Bakt. u. Par., 1. Abt., Orig., 36 (1904), No. 3, pp. 427–441*).—On the basis of his experiments the author concludes that normal horse serum agglutinates typhoid bacilli in dilutions of 1:100. Dead typhoid bacilli are similarly agglutinated at temperatures of 60 to 62° C. Distinction is made by the author between agglutinins and agglutinoids in normal immune sera.

Epizootic lymphangitis, GRAY (*Rhodesian Agr. Jour., 1 (1904), No. 4, pp. 78–80*).—The symptoms and etiology of this disease are briefly described. It is said to be amenable to treatment if taken in time. Carbolic acid and other antiseptics are recommended.

The varieties of Bacillus œdematis maligni, KIRSTEN (*Arch. Wiss. u. Prakt. Tierh., 30 (1904) No. 3, pp. 223–260*).—The purpose of these investigations was to determine whether the bacillus of malignant edema is a sharply defined and invariable species or a group of varieties. The literature of the subject is critically discussed in connection with an extensive bibliography.

The author describes in detail a number of types of this organism as determined by morphological, biological, and pathogenic properties. It is concluded that the edema bacillus, like many other bacterial species, forms a group of varieties which may readily be distinguished. The most of the varieties are only slightly or not at all pathogenic.

A comparison of Klein's yeast with other pathogenic yeasts, E. COHN (*Centbl. Bakt. u. Par., 1. Abt., Orig., 36 (1904), No. 3, pp. 369–379*).—The experimental investigations with pathogenic yeasts are briefly described. Attention is called to the necessity of giving strict heed to the age and other conditions of yeast cultures in studying their biology and pathogenic action.

Relations of Federal Government to control of contagious diseases of animals, D. E. SALMON (*U. S. Dept. Agr. Yearbook 1903, pp. 491–506*).—The work of this Department in preventing the spread of contagious diseases of animals is outlined with notes on the diseases to which most attention is given, the necessity of the control of contagion by the Federal Government, and the results obtained. Particular attention is given to the discussion of sheep scab, cattle scab, and Texas fever.

Report of the veterinarian, L. VAN ES (*North Dakota Sta. Rpt. 1903, pp. 124–131, pls. 3, figs. 4*).—During the short time the veterinarian has been connected with the station his work has consisted of field and laboratory investigations on various live-stock diseases.

Some active work has been begun, particular attention being paid to the scab or scabies among station cattle. As the conditions at the station are in a large degree similar to those prevailing throughout the State, the methods adopted are described at length. The treatment consists of dipping animals, for which purpose two types of apparatus are in use; one for large herds where the animals are driven through the vat, the other for use on a smaller scale, which consists of a small vat in the ground and movable cage in which the animal is placed and lowered into the tank. The dipping fluid used was a lime and sulphur mixture.

In cooperation with the assistant botanist, experiments were begun to study the effect of the ingestion of *Zygadenus elegans* on animals. A number of cases of stock poisoning have been attributed to this plant and investigations were conducted with a view to determining its poisonous properties. Only a small quantity of the plant could be obtained when the work was done, but with this rabbits were fed or received hypodermic injections of extracts made from the plant. In most cases negative results were obtained and efforts will be made to continue experiments not only on rabbits, but cattle and sheep during the coming season.

The Bacteriological Institute at Landsberg and the preparation and testing of sera, SCHUBERT (*Deut. Tierärztl. Wchnschr., 12 (1904), No. 18, pp. 169–172*).—A detailed account is given of the sera prepared in this institute for use in the treatment of swine erysipelas, swine plague, hog cholera, fowl cholera, and septic pneumonia of calves.

Combating bovine tuberculosis, G. MAZZINI (*Gior. R. Soc. ed Accad. Vet. Ital., 53 (1904), No. 23, pp. 540–544*).—A short outline is presented of various methods which have been suggested for controlling tuberculosis in cattle, including that of von Behring. Attention is called to the danger from consuming the milk and meat of tuberculous animals, and to the necessity of more severe methods in controlling the disease in Italy.

The effect of treatment with hetol upon inoculation tuberculosis of guinea pigs and rabbits, A. HOFFMANN (*Arch. Wiss. u. Prakt. Tierh., 30 (1904), No. 1–2, pp. 162–187*).—The literature relating to the treatment of tuberculosis by the use of hetol is critically reviewed. The chemical nature of hetol is discussed. In healthy rabbits and guinea pigs hetol in doses of 1 cc. of a 1 per cent solution produced slight elevation of temperature.

It was found that animals inoculated with tuberculosis and treated with hetol withstood infection considerably longer than the control animals. Striking differences were observed in the histological characters of the tissues of treated and untreated animals. In treated animals the tubercles were small, sharply delimited, and surrounded by leucocytes. Furthermore, treated animals gained in weight while untreated ones lost. Hetol may without any injurious effect be given to rabbits and guinea pigs hypodermically or intravenously in ½ per cent to 1 per cent solutions in doses of 1 cc.–2 cc. It is more effective when given intravenously than by the hypodermic method.

The author considers hetol a very satisfactory remedy and believes that it materially aids the animal in resisting the progress of tuberculosis.

Erroneous diagnosis of tuberculosis in cows, LIÉNAUX (*Ann. Méd. Vét., 53 (1904), No. 6, pp. 339–343*).—A milch cow showed loss of appetite and weight, with body temperature of 40° C. The case was diagnosed on the basis of physical symptoms as tuberculosis. On post-mortem examination the lungs were found to be free from tubercles. The case proved to be one of infectious lymphadenitis. Detailed notes are given on the pathological lesions.

The tuberculin reaction, FEISTMANTEL (*Centbl. Bakt. u. Par., 1. Abt., Orig., 36 (1904), No. 3, pp. 406–415*).—The toxic effect of large doses of glycerin has little or no influence in the production of a reaction to tuberculin in guinea pigs. Salt solutions are similarly without effect. It was found that from cultures of *Streptothrix farcinica* a toxin could be obtained which had the same action as tuberculin. The tuberculin reaction is therefore considered of a generic rather than specific character. The tubercle bacillus and *Streptothrix farcinica* are believed to be closely related.

Rhodesian tick fever, A. THEILER (*Transvaal Agr. Jour., 2 (1904), No. 7, pp. 421–438, pl. 1*).—The nature, symptoms, etiology, and pathology of this disease are described in considerable detail. The disease can not be transmitted by a single inoculation of virulent blood. The developmental stages of the blood parasite are described and notes are given on the biology and habits of *Rhipicephalus appendiculatus*, by means of which the disease is transmitted. The disease is carried only by the nymphal and adult stages of this tick. Treatment of Rhodesian tick fever is of no avail, but immunity may be produced by inoculation.

Rhodesian redwater, R. KOCH (*Arch. Wiss. u. Prakt. Tierh., 30 (1904), No. 3, pp. 281–319*).—This is essentially a German translation of the author's first three reports on this subject as already noted from English publications (E. S. R., 15, pp. 301, 1014, 1126).

The tick disease of cattle (hæmoglobinæmia ixodioplasmatica boum) in German and English East Africa and Uganda, A. SCHMIDT (*Arch. Wiss. u. Prakt. Tierh., 30 (1904), No. 1-2, pp. 42-101*).—The literature of this subject is discussed with references to a bibliography of 221 titles. An elaborate review is given of the history, symptoms, pathogenesis, etiology, and treatment of the disease. The developmental stages of the blood parasites are described and notes are given on the natural history of the ticks. The author argues that one set of quarantine regulations would be effective in controlling Texas fever, rinderpest, and tsetse-fly disease.

Trypanosoma theileri in German East Africa, O. PANSE (*Ztschr. Hyg. u. Infectionskrank., 46 (1904), No. 3, pp. 376-378, fig. 1*).—Specimens of an organism supposed to belong to this species were found in cattle on the island of Mafia. Notes are given on its morphological characters.

An African trypanosome pathogenic for horses, A. LAVERAN and F. MESNIL (*Compt. Rend. Acad. Sci. Paris, 138 (1904), No. 12, pp. 732-737, fig. 1*).—Notes are given on the morphological characters of *Trypanosoma dimorphon*. This parasite is pathogenic for rats, mice, rabbits, dogs, goats, horses, etc.

Some of the more recent work on the morphology of anthrax bacillus, A. GRIMME (*Centbl. Bakt. u. Par., 1. Abt., Orig., 36 (1904), No. 3, pp. 352-354*).—The author gives a brief review of recent literature on this subject. The fat globules of anthrax bacilli are spherical, highly refractive, and do not stain with ordinary anilin dyes. They are dissolved in chloral hydrate but not in Eau de Javelle.

Correction to the article of D. Ottolenghi "On the minute structure of anthrax bacillus," V. RUZICKA (*Centbl. Bakt. u. Par., 1. Abt., Orig., 36 (1904), No. 3, p. 354*).—A controversial article regarding the staining of anthrax bacillus.

The mechanism of natural immunity to anthrax, L. REMY (*Bul. Inst. Chim. et Bact. Gembloux, 1904, No. 74, pp. 1-32*).—A long series of experiments was carried out for the purpose of determining the bodies in the serum of white rats, rabbits, guinea pigs, goats, and horses.

On the basis of these experiments the author concludes that natural immunity is subject to the same laws which regulate artificial immunity. The bactericidal power of normal sera should not be attributed to the alexin entirely, but partly to the immune body. The author considers artificial immunity not as a means of defense on the part of the affected organism, but as an exaltation of the process of destructive digestion of pathogenic bacteria. The destruction of bacteria by means of sera in vitro is comparable with the artificial digestion of proteid substances.

The artificial immunity of rabbits to anthrax, O. BAIL (*Centbl. Bakt. u. Par., 1. Abt., Orig., 36 (1904), No. 3, pp. 397-406*).—The serum of immunized rabbits may be rendered practically inactive against anthrax bacilli by admixture of cellular material. The addition of bone-marrow cells, however, brings about the death or attenuation of the anthrax bacilli. The immune serum appears to be not bactericidal but rather antitoxic.

Blackleg, C. BIANCHI (*Gior. R. Soc. ed Accad. Vet. Ital., 53 (1904), No. 21, pp. 481-485*).—A brief account is presented of the symptoms and treatment of blackleg. The causes of death after vaccination are discussed.

The bacterial content of muscle tissue affected with blackleg and of blackleg vaccine, H. REGN (*Arch. Wiss. u. Prakt. Tierh., 30 (1904), No. 3, pp. 261-280*).—An attempt was made to determine quantitatively and qualitatively the blackleg bacilli in musculature and vaccine. The author made numerous aerobic and anaerobic cultures on various media and inoculation experiments with animals. The number of spores in blackleg muscles was found to vary enormously, being most numerous in spontaneous cases, in which a maximum of 1,202,000 per mg. was observed.

In experimental anthrax in cattle the number of spores varied from 215 to 133,000 per mg. of affected muscle, and in sheep from 410 to 2,100. The number of spores varies

with the age of the material, being less in older material. Attenuation of the material diminished the number of spores. Several species of saprophytic organisms were found in blackleg vaccine. Some of these are usually found in healthy cattle.

Vaccination against blackleg by the method of O. Thom s in Verdun, A. GUILLEBEAU (*Schweiz. Arch. Tierh., 46 (1904), No. 2, pp. 57-61*).—The author refers to the recent introduction of "blacklegine" into Germany and to the claims which have been made regarding its efficacy. The experience thus far had with this method does not seem sufficient, and the author prefers to wait for further data before coming to a final conclusion as to the value of the remedy.

Foot-and-mouth disease, GRAY (*Rhodesian Agr. Jour., 1 (1904), No. 4, pp. 83, 84*).—The author describes the symptoms and lesions of this disease in various animals, including camels.

Intravenous treatment of foot-and-mouth disease, G. MAZZINI (*Gior. R. Soc. ed Accad. Vet. Ital., 53 (1904), Nos. 2, pp. 31-37; 4, pp. 79-84; 6, pp. 131-136; 8, pp. 175-182; 9, pp. 200-203*).—A summary is presented of the results obtained in the intravenous use of corrosive sublimate in treating foot-and-mouth disease in France, Germany, Belgium, Roumania, Switzerland, Spain, Portugal, and Italy. From this elaborate review of the literature of the subject it is concluded that the method is worthless.

The pathogenic action of certain Streptothrix (Actinomycosis) species, F. SAUFELICE (*Centbl. Bakt. u. Par., 1. Abt., Orig., 36 (1904), No. 3, pp. 355-367*).—The author presents a systematic classification of this group of micro-organisms, with notes on the pathogenic action of various species. It was found to be impossible to obtain by inoculation of dogs a serum which would increase the resisting power of rabbits to infection with actinomycosis.

Hematuria in cattle, DETROYE (*Bul. Soc. Cent. Méd. Vét., 81 (1904), No. 6, pp. 187-193*).—Positive results were obtained in 10 out of 17 cases in which it was sought to transmit the disease by direct inoculation. Detailed notes are given on the technique of these experiments.

Malignant catarrhal fever of cattle, ISEPPONI (*Schweiz. Arch. Tierh., 46 (1904), No. 1, pp. 1-12*).—An outbreak of this disease occurred in which the symptoms were not of the usual nature. From his study of the disease the author concludes that it occurs sporadically or sometimes as an enzootic.

The disease may be mistaken for foot-and-mouth disease, rinderpest, meningitis, and dysentery. It is apparently not communicable immediately from animal to animal. The pathogenic organism is found in the soil, where it retains its virulence for long periods. When affected animals are killed before the croupous-diphtheritic symptoms appear the meat is suitable for food. The disease is fatal if allowed to reach full development. It may be controlled by quarantine, thorough disinfection, and serum treatment.

Inoculation against pleuro-pneumonia, sequels and complications, A. THEILER (*Transvaal Agr. Jour., 2 (1904), No. 7, pp. 357-368, pl. 1*).—An elaborate historical account is given of the methods of inoculation against this disease. The methods of vaccination are described and notes are given on their effect upon healthy cattle. Complications from inoculation are often manifested by lesions in the throat, peritoneum, or elsewhere. In the author's experience the duration of artificial immunity is about 1 year, occasionally 18 months.

Trichophyton tonsurans of cattle, POËNARU (*Bul. Soc. Cent. Méd. Vét., 81 (1904), No. 10, pp. 328, 329*).—This disease may be transmitted from cattle to man, but such is not commonly the case. The author classifies *Trichophyton tonsurans* with the yeasts.

The operative treatment of skin warts on cattle, M. STREBEL (*Schweiz. Arch. Tierh., 46 (1904), No. 1, pp. 12-17*).—Warts appear most frequently on young cattle, and preferably on the udder, inner surface of the thighs, and lower parts of the

abdomen. These warts may be classified into two groups, one group containing hard, horny outgrowths and the other containing softer tumors of various sizes beneath the skin. In the treatment of warts the author believes that surgical removal is far more satisfactory than the external application of caustic drugs.

Milk fever; its simple and successful treatment, J. R. Mohler (*U. S. Dept. Agr., Bureau of Animal Industry Circ. 45, pp. 13, figs. 2*).—Milk fever is described with particular reference to its cause, symptoms, distribution, pathological anatomy, prognosis, and treatment. The various lines of treatment which have been applied to this disease are described. Perhaps the simplest and most effective remedy consists in the distension of the udder with filtered atmospheric air.

At the suggestion of the author a convenient apparatus was devised for injecting air into the udder. The operation can be done by the ordinary dairyman, but it is recommended that, where possible, veterinarians be called. In preventing the development of milk fever, Epsom salts in 1-lb. doses may be administered for 2 or 3 days before calving, and some milk may be left in the udder at each milking for the first few days after calving.

Pathogenesis and treatment of milk fever, Hebbelynck (*Ann. Méd. Vét., 53 (1904), No. 1, pp. 16–25*).—The different theories regarding the etiology of milk fever are briefly discussed. The author inclines to the view that the disease will ultimately be found to be due to a pathogenic organism, and expresses the hope that a successful serum treatment may be devised.

Treatment of milk fever, N. F. Andreev (*Arch. Vet. Nauk. St. Petersburg, 34 (1904), No. 4, pp. 320, 321*).—An account is given of the treatment of milk fever by Schmidt's method and with atmospheric air. The author tested the latter method in 4 cases with very satisfactory results. The cows were able to stand up within 1 to 2 hours after treatment.

Investigation of "yellow galt," E. Zschokke (*Schweiz. Arch. Tierh., 46 (1904), No. 3, pp. 113–126*).—Statistics are given on the frequency of this mammary disease which appears to be enzootic in certain localities. The cause of the disease is infection with streptococci. The mode of infection is, however, not well understood. Cows inoculated in the milk cistern with pure cultures of streptococci showed elevation of body temperature, decrease in milk secretion, and pus corpuscles in the milk. No successful treatment of the disease has been devised, and attention is called to the urgent need of further investigation along this line.

Obstructions to the flow of milk, G. Giovanoli (*Schweiz. Arch. Tierh., 46 (1904), No. 1, pp. 20–22, fig. 1*).—A brief discussion of various causes of obstruction of the milk flow, due to pathological conditions of the udder or teats.

Some results from spaying milch cows, J. Jacobs (*Ann. Méd. Vét., 53 (1904), No. 2, pp. 73–83, figs. 2*).—A description is given of various instruments used in performing this operation. The method adopted was that of ligation of the oviduct without removal of the ovaries. The milk flow was maintained and the procedure is recommended as a wise practice.

Spaying milch cows, Degive (*Ann. Méd. Vét., 53 (1904), No. 1, pp. 1–16, pl. 1*).—The somewhat unsatisfactory results thus far obtained in spaying cattle are explained as due to the use of improper methods of operation. It is recommended that the operation be performed only on cattle in health and 8 or 9 hours after their last feed. Strict antiseptic precautions are urged. The oviducts may be successfully ligatured with silk thread.

Pseudo-epizootic abortion, Cagny (*Bul. Soc. Cent. Méd. Vét., 81 (1904), No. 10, pp. 320–322*).—Brief notes on pathological conditions which may be mistaken for this disease.

Infectious arthritis of calves, E. Thierry (*Jour. Agr. Prat., n. ser., 7 (1904), No. 18, p. 584*).—In preventing this disease it is recommended that the navel be dis-

infected by washing with a solution of iodin and iodid of potash followed with an alcoholic solution of iodin.

A case of cerebro-spinal meningitis in a calf, B. ANTONIO (*Gior. R. Soc. ed. Accad. Vet. Ital., 53 (1904), No. 17, pp. 396-398*).—A calf 20 days old developed a marked case of cerebro-spinal meningitis, resulting in death. A body temperature of 41° C. was reached. This case was believed to be one of the bacterial forms of the disease. The meninges were much injected and the lungs congested.

Alleged indiscriminate inoculation of cattle (*Rhodesian Agr. Jour., 1 (1904), No. 4, pp. 73-78*).—A thorough discussion is presented of certain reports regarding unsatisfactory results from inoculation of cattle by private individuals and persons of insufficient training. No bad results have occurred where inoculated stock have been kept under proper care and isolation and where the inoculation process has been properly carried out.

Scabies in sheep and cattle and mange in horses, L. VAN ES (*North Dakota Sta. Bul. 61, pp. 399-435, figs. 24*).—Detailed notes are given on the cause, symptoms, distribution, diagnosis, and treatment of sheep scab. The lime-sulphur dip is recommended as one of the most effective means of curing the disease. It is held that this dip causes no serious harm to the wool.

Directions are given for preparing and applying the dip, and for the preparation of dipping plants for the treatment of cattle scab. The lime-sulphur dip is recommended for this disease also, in the proportion of 21 lbs. sulphur and 16¾ lbs. lime per 100 gal. of water. The temperature of the dip should be between 102° and 112° F., in order to insure the best results. The treatment suggested for mange in horses consists in removing the scabs from affected parts and applying creolin or some other insecticide. Horses can not be dipped so successfully as cattle or sheep.

Verminous broncho-pneumonia of sheep, G. SAINT-HILAIRE (*Bul. Agr. Algérie et Tunisie, 10 (1904), No. 8, pp. 173-179*).—In 1903 this disease prevailed extensively in the northern part of Algeria. The parasites concerned were *Strongylus filaria* and *S. rufescens.* Notes are given on the symptoms, pathology, and treatment of the disease. Various methods of inhalation of fumes and intratracheal injections for the treatment of the disease are described.

Results of experiments with nodule disease of the intestines of sheep, W. H. DALRYMPLE (*Louisiana Stas. Bul. 79, 2. ser., pp. 16, figs. 2*).—The symptoms and pathological lesions of nodule-disease in sheep are briefly described.

The author conducted a number of experiments for the purpose of determining the method of infestation of sheep with this worm and also methods of eradicating the worm from infested pastures. It was found during these experiments that infested sheep may distribute the worms upon clean pastures and transmit infection to healthy sheep which may subsequently graze upon these pastures. When infested pastures are plowed and cultivated for a single season the infestation may be destroyed and lambs may safely be allowed to graze upon this land when subsequently allowed to run to pasture. The offspring of infested ewes may be raised in a healthy condition upon the exercise of proper precautions.

It was suggested that while this disease appears to be widely distributed throughout nearly all of the old pasture lands used for sheep, it might be eradicated by plowing and cultivation of such pastures and the destruction of the intestines of the infested sheep.

Swine plague, W. GRIPS ET AL. (*Fortschr. Vet. Hyg., 2 (1904), No. 4, pp. 113-135*).—It is maintained that the organism discovered by Grips and not the one discovered by Löffler is the cause of swine plague, which is considered a purely contagious disease of young hogs characterized by catarrh and suppurative processes. Infection usually takes place by way of the mouth. The Löffler bacillus is merely instrumental in causing acute complications. Distinction is made between swine erysipelas, swine plague, and hog cholera.

Shall veterinarians continue to vaccinate with cultures of swine erysipelas? KLEINPAUL (*Berlin. Tierärztl. Wchnschr., 1904, No. 16, pp. 303–306*).—Some writers on this subject have contended that vaccination with serum and culture of swine erysipelas is no protection against the disease but, on the contrary, contributes to its wider distribution. The author states, however, that hog raisers have found such vaccination necessary in order to secure a profit from the hog industry. Attention is called to the very important and reliable results obtained in the control of swine erysipelas by this method. The disease is not spread by vaccination. The method has only one disadvantage, viz, that the immunity thus produced is of short duration.

Report on pig disease in the Umtali district, G. V. S. JARVIS (*Rhodesian Agr. Jour., 1 (1904), No. 6, pp. 176, 177*).—The disease prevails most extensively during the rainy season. The rate of mortality is high. The symptoms and lesions are described in detail. Sty-fed hogs are seldom affected. Several species of ticks were found on diseased hogs. The affection does not appear to be contagious.

Sarcoptic mange in hogs, A. SCHOLL (*Ann. Méd. Vét., 53 (1904), No. 5, pp. 284–290*).—The symptoms of hog mange as caused by infestation with *Sarcoptes scabiei suis* are described and notes are given on the course of the disease, its distribution, transmission to other animals and man, and its treatment.

The leucocytes of horse blood, BIDAULT (*Bul. Soc. Cent. Méd. Vét., 81 (1904), No. 10, pp. 315–317*).—An elaborate review of this subject, together with personal investigations by the author, is considered to be of great value by the Veterinary Commission of France.

Horse sickness experiments, A. THEILER (*Transvaal Agr. Jour., 2 (1904), No. 7, pp. 332–334*).—Recovered animals are immune to the disease. Immunity may also be produced by simultaneous injection subcutaneously of serum and virus. The most certain and effective immunity, however, is produced by simultaneous injection of virus intravenously and serum subcutaneously. The duration of the inoculation is about 12 days.

Glanders in German East Asia, SCHLIE (*Berlin. Tierärztl. Wchnschr., 1904, No. 13, pp. 238, 239*).—A description is given of the clinical history and pathological lesions of glanders cases in a horse and a mule. The usual quarantine and disinfection measures were enforced in order to prevent the further spread of the disease among other army horses.

Hasty diagnosis in the case of horses suspected of glanders, A. DI GIROLAMO (*Gior. R. Soc. ed Accad. Vet. Ital., 53 (1904), No. 9, pp. 194–200*).—It is recommended that all suspected horses be properly quarantined and premises disinfected, after which a reliable diagnosis may be made.

The antiseptic action of glycerin and methyl violet on the glanders bacillus, G. ANGELICI (*Rec. Méd. Vét., 81 (1904), No. 1, pp. 14–18*).—Virulent cultures of the glanders bacillus were shaken up in sterile glycerin and left standing at various temperatures. It was found that the virulence was entirely destroyed after an exposure of 4 to 6 days, as determined by inoculation experiments with rabbits and guinea pigs. Methyl violet (5 parts to 1,000) destroyed the virulence of *Bacillus malleus* and *B. pyocyaneus* after exposure for 40 to 50 days.

Dourine and its treatment, E. MARCHAL (*Rec. Méd. Vét., 81 (1904), No. 7, pp. 231–237*).—Continued experiments have corroborated the author's previous work in showing that dourine may be successfully treated with cacodylate of soda. When given by way of the mouth this remedy may be decomposed into somewhat irritant and toxic substances. It is advisable therefore to administer the drug subcutaneously. The author treated six cases in horses, in which the characteristic symptoms were present and trypanosomata in the blood, as shown by inoculation of dogs. Of these 6 horses, 5 made a complete recovery. The author therefore considers the remedy a very satisfactory one for the treatment of dourine.

Etiology, pathogenesis, and treatment of equine paraplegia, PÉRICAUD (*Bul. Soc. Cent. Méd. Vét., 81 (1904), No. 4, pp. 55–58*).—This disease is also known under the name hemoglobinemia. Notes are given on several cases in which the author obtained good results from treatment with a mixture containing 5 parts potassium chlorid, 1 part potassium sulphate, 2 parts basic phosphate of potash, 1 part basic phosphate of soda, and 1 part soda. The mixture is injected subcutaneously.

Colic in horses (*Bul. Soc. Cent. Méd. Vét., 81 (1904), No. 4, pp. 59–80*).—This is a sort of symposium on the subject and contains clinical notes and discussions on numerous cases with an account of the etiology of the disease and the most promising lines of treatment.

Cerebral tumors in horses, R. BISSAUGE and NAUDIN (*Rec. Méd. Vét., 81 (1904), No. 1, pp. 5–9*).—A brief general account of cerebral tumors is given, together with detailed notes on a case which came under the author's observation. The horse had frequent attacks of cerebral congestion and depression without fever. Cold applications and purgatives were given with apparently good results. The animal finally had to be killed and notes are presented on the lesions observed during the post-mortem examination.

Perforative epithelioma of the upper jaw in the horse, G. GANCOLA (*Gior. R. Soc. ed Accad. Vet. Ital., 53 (1904), Nos. 1, pp. 10–13; 2, pp. 25–31; 3, pp. 57–63, figs. 3*).—The author discusses the various theories which have been proposed to explain the etiology of malignant tumors. Notes are given on the structure of maxillary epithelioma as observed in horses.

Poultry diseases, G. ANGELICI (*Gior. R. Soc. ed Accad. Vet. Ital., 53 (1904), No. 5, pp. 110–114*).—Spirillosis of fowls was found to be transmissible by inoculation with virulent blood or fresh serum. Immunity may be brought about by recovery from a mild attack of the disease or by inoculation with serum containing dead spirilla. Experiments are reported on the passage of fowl cholera organisms through filters. Brief notes are also given on tumors of fowls.

The diagnosis of rat plague, KISTER and P. SCHMIDT (*Centbl. Bakt. u. Par., 1. Abt., Orig., 36 (1904), No. 3, pp. 454–457, pl. 1*).—Ferrets used in the destruction of rats developed a disease which rapidly killed large numbers of them. From cases of this disease an organism was isolated which resembled the plague bacillus and which proved to be pathogenic for all ordinary experimental animals. Agglutination tests showed that the micro-organism is specifically distinct from the plague bacillus.

The use of ichthargan in veterinary practice, J. JOST (*Berlin. Tierärztl. Wchnschr., 1904, No. 14, pp. 257–259*).—The author used ichthargan per os, externally, and intravenously in the treatment of morbus maculosus, septicemia, fistulous withers, enteritis, dog distemper, and other diseases. Ichthargan proved much more effective than colloidal silver in cases of morbus maculosus. When given in cases of septicemia, the drug caused a prompt lowering of the temperature and healing of the skin wound by granulation. In the gastric form of dog distemper ichthargan per os had a markedly beneficial effect.

Adulterated linseed oil for veterinary purposes, P. SCHWEITZER (*Missouri Sta. Rpt. 1903, pp. 27, 28*).—An oil which had been sold for linseed, and which caused the death of cattle to which it had been administered as a medicine, was found to contain lead, naphtha, resin oil, and other oils than linseed, showing that the material was an impure boiled oil.

Comparative study of the antiseptic action of different alcohols, G. WIRGIN (*Ztschr. Hyg. u. Infectionskrank., 46 (1904), No. 1, pp. 149–168*).—The different alcohols were tested to determine their antiseptic power toward *Micrococcus pyogenes aureus*. It was found that their action varied as their molecular weight, methyl alcohol being least and amyl most active. Isomeric alcohols are nearly equal in antiseptic power. The hemolytic action of alcohols also varies as the molecular weights. None of the alcohols kills spores at ordinary temperatures. The most

powerful alcoholic mixtures are more active than a 4 per cent solution of boric acid or a 2 per cent solution of zinc sulphate.

AGRICULTURAL ENGINEERING.

Water resources of the Salinas Valley, California, H. HAMLIN (*U. S. Geol. Survey, Water-Supply and Irrig. Paper No. 89, pp. 91, pls. 12, figs. 30*).—"This report is based on investigations made by the United States Geological Survey, cooperating with the board of supervisors of Monterey County and the California Water and Forest Association, in Monterey County, Cal., during 1900, 1901, and 1902. The work was done under the supervision of Mr. J. B. Lippincott, resident hydrographer of the United States Geological Survey.

"The report relates particularly to that portion of the Salinas Valley that lies within the boundaries of Monterey County, and describes the topography, hydrography, and economic geology of a portion of the region. It also discusses the extent of the underground water, the methods of irrigation, the irrigation systems, and the possibility of extending irrigation by the utilization of surface streams and by impounding flood waters."

Geology and water resources of part of the lower James River Valley, South Dakota, J. E. TODD and C. M. HALL (*U. S. Geol. Survey, Water-Supply and Irrig. Paper No. 90, pp. 47, pls. 23*).

Review of irrigation investigations for 1903, E. MEAD (*U. S. Dept. Agr., Office of Experiment Stations Rpt. 1903, pp. 469–502, pls. 6*).—A résumé is given of irrigation investigations during the year in various States in the arid, semi-arid, and humid portions of the United States, with brief accounts of drainage investigations in different parts of the United States and of studies of laws and social institutions of irrigated regions in the United States and Italy, a statement regarding the collection and publication of information as to methods employed in the practical operations of irrigation farming, and a list of publications issued during the year.

Preparing land for irrigation, R. P. TEELE (*U. S. Dept. Agr. Yearbook 1903, pp. 239–250, pls. 2, figs. 5*).—A description is given of methods actually in use in the irrigated region for removing sagebrush and stones, smoothing and leveling land, locating and building farm laterals, and preparing land for irrigation by the check system and for the use of metal pipes and canvas hose.

Irrigation in the valley of Lost River, Idaho, A. E. WRIGHT (*U. S. Dept. Agr., Office of Experiment Stations Circ. 58, pp. 24*).—The results of sinkage measurements during August, 1903, at different points on this river, which sinks in its bed and rises again to the surface several times in its course, are summarized and discussed with reference to irrigation practices and water rights.

Railway embankments and irrigation, K. A. WIDEGREN (*Agr. Jour. Cape Good Hope, 25 (1904), No. 1, pp. 43–46, fig. 1*).—The possibility, advantages, and means of utilizing railway embankments as dams for storage of water for irrigation are briefly discussed.

Seepage investigations in the valley of the Laramie River, B. P. FLEMING (*Wyoming Sta. Bul. 61, pp. 32, figs. 3*).—The nature, extent, and means of prevention of seepage losses are discussed. Seepage measurements on the Laramie River as it passes through the Laramie Plains, on several canals which divert water from the river, and on Sand Creek, are reported. The results are summarized as follows:

"(1) The Laramie River throughout its length gains a varying, but always appreciable, amount of water by seepage from adjoining lands, the gain averaging 0.42 second feet per mile, the highest gains being 1.00 second foot per mile, near Woods Landing, and the lowest 0.06 per mile, below Reservoir No. 2.

"(2) All the canals investigated show large losses by seepage, the largest losses occurring on the highline canals, the smallest on the canals in the river bottoms.

"(3) The average loss per mile from canals, excluding the Divide Ditch, amounts to 5.79 per cent of the volume carried per mile, or 1.08 second feet per acre of wetted perimeter. The highest losses in terms of the volume carried occurred on the Divide Ditch and Highline Canal, amounting, respectively, to 50.2 per cent and 17.5 per cent.

"(4) It is probable that seepage has a greater influence in sustaining stream flow, and consequently in increasing the acreage of land irrigated, than is commonly known. As shown from results on Sand Creek and the Laramie River, the same water is undoubtedly diverted and used many times in succession."

Drainage conditions in Iowa, W. H. STEVENSON, G. I. CHRISTIE, and L. E. ASHBAUGH (*Iowa Sta. Bul. 78, pp. 237–263, figs. 4*).—This bulletin contains a discussion of the need and advantages of drainage in Iowa, based on results of an extended investigation of drainage conditions in the State, with notes and tables showing the grades and sizes of drains to be used under different conditions, the cost of tile drains, and forms of contracts and specifications for drainage. The order of procedure under the new State drainage law is also explained.

It is stated that "over four million acres of Iowa land would be greatly benefited by tile drainage. A very large percentage of this number was wholly unproductive last year. The direct financial loss to the State last season through lack of adequate drainage was approximately $20,000,000. The rapid rise in land values makes tile drainage imperative; it also makes it a profitable investment. Under-draining benefits rolling lands. It prevents the loss of the most valuable part of the soil through washing and by removing the surplus ground water prevents seepage. . . . By facilitating the cultivation and harvesting of otherwise broken fields drainage lessens the cost of crop production. Rotation of crops is essential to successful farming. On thousands of farms throughout the State well-planned, systematic drainage can alone make this possible."

Supplemental report on drainage in the Fresno district, California, C. G. ELLIOTT (*U. S. Dept. Agr., Office of Experiment Stations Circ. 57, pp. 5, fig. 1*).—This circular, which is supplementary to No. 50 of this Office (E. S. R., 15, p. 94), summarizes the results of observations in a series of 7 wells which were sunk to a depth of 8 ft. in the drained area for the purpose of studying the movement of the soil water. The bearing of the results upon the efficiency of the drainage system previously described is discussed.

Progress of road building in the Middle West, R. W. RICHARDSON (*U. S. Dept. Agr. Yearbook 1903, pp. 453–462, pls. 3*).—The topics discussed in this article are forces at work for highway improvement, the rural population and the roads, reasons for lack of progress in road building, State and National aid, antiquated methods, road laws and conditions in several States, road material, road construction, and educational work.

Building sand-clay roads in southern States, W. L. SPOON (*U. S. Dept. Agr. Yearbook 1903, pp. 259–266, pls. 2, figs. 3*).—Several examples of typical sand-clay roads are described and the methods of constructing them are explained. It is claimed that "the building of sand-clay roads has passed the experimental stage, and it is no longer a question of doubtful procedure.

"The important things to be borne in mind are thorough mixing to the saturation point, and then properly shaping and rolling the road. This mixing is usually done by the traveling public. This is the critical period in the construction of a sand-clay road, because care must be taken to secure an even amount of puddling, so that all the lumps of clay shall be broken and saturated with sand to a depth of 8 to 10 in. If this can be done and the road is properly crowned as it dries, there can be no doubt about the result being eminently satisfactory.

"This mixing might be done by the use of plows and harrows when the clay is wet, but it is customary to let teams and vehicles accomplish it. It is true that the

condition of the road becomes worse for a while during the puddling operation; but after this is effected and sufficient sand has been added relief is permanent."

The value of different motive powers in agriculture, H. HOLLDACK (*Fühling's Landw. Ztg., 53 (1904), No. 14, pp. 509–518, figs. 8*).—This article describes and discusses the efficiency of the steam turbine motor.

Trials of mowers and selfbinders at Alnarp, G. TIMBERG (*Landtmannen, 14 (1903), No. 37, pp. 578–582*).—Four machines of 3 different makes were included in the trials.

Trials of cultivators, planters, and feed mills at Alnarp, G. TIMBERG (*Landtmannen, 14 (1903), No. 38, pp. 593–597*).

MISCELLANEOUS.

Annual Report of the Office of Experiment Stations, 1903 (*U. S. Dept. Agr., Office of Experiment Stations Rpt. 1903, pp. 758, pls. 60*).—This contains the usual report on the work and expenditures of the agricultural experiment stations in the United States; annual reports of the experiment stations in Alaska, Hawaii, and Porto Rico; reviews of irrigation and nutrition investigations, and several other articles abstracted elsewhere in this issue.

Included in the report on the work and expenditures of the stations are statistical summaries; brief reports of nutrition and irrigation investigations; summarized accounts of the meetings of the Association of American Agricultural Colleges and Experiment Stations and the American Association of Farmers' Institute Workers; a review of the work of this Office; a report of the governing board, station, staff, general outline, lines of work, income, and publications of each experiment station; a list of station publications received by this Office during 1903; federal legislation, regulations, and rulings affecting agricultural colleges and experiment stations, etc.

Yearbook of the Department of Agriculture, 1903 (*U. S. Dept. Agr. Yearbook 1903, pp. 728, pls. 65, figs. 54*).—The Yearbook, as in the past, contains a general report on the work of the Department during the year by the Secretary of Agriculture; numerous semipopular articles, and an appendix consisting of a summary of information on various subjects of interest to the farmer. The 32 articles included in the present Yearbook are noted elsewhere in this issue. The proposed new buildings of the Department of Agriculture are described by B. T. Galloway, chairman of the building committee.

Annual Report of Missouri Station, 1899 (*Missouri Sta. Rpt. 1899, pp. 7*).—This contains a brief report of the director and a financial statement for the fiscal year ended June 30, 1899.

Annual Report of Missouri Station, 1900 (*Missouri Sta. Rpt. 1900, pp. 7*).—This contains a brief report of the director and a financial statement for the fiscal year ended June 30, 1900.

Annual Report of Missouri Station, 1901 (*Missouri Sta. Rpt. 1901, pp. 7*).—This contains a brief report of the director and a financial statement for the fiscal year ended June 30, 1901.

Annual Report of Missouri Station, 1902 (*Missouri Sta. Rpt. 1902, pp. 7*).—This contains a brief report of the director and a financial statement for the fiscal year ended June 30, 1902.

Annual Report of Missouri Station, 1903 (*Missouri Sta. Rpt. 1903, pp. 31*).—This contains a brief report of the director; a financial statement for the fiscal year ended June 30, 1903, and several articles noted elsewhere.

Fourteenth Annual Report of North Dakota Station, 1903 (*North Dakota Sta. Rpt. 1903, pp. 254*).—This includes the organization list of the station; a brief report of the director; somewhat extended reports of the heads of departments, noted elsewhere; a financial statement for the fiscal year ended June 30, 1903, and a reprint

of Bulletin 59 of the station, entitled Trees and Fruits in North Dakota (E. S. R., 15, p. 971).

Thirteenth Annual Report of Utah Station, 1902 (*Utah Sta. Rpt. 1902, pp. LVIII*).—This contains a report of the director; departmental reports, and a financial statement for the fiscal year ended June 30, 1902. The report of the agronomist giving the results of some experimental work is noted elsewhere. The other reports are brief reviews of the different lines of station work.

Proceedings of the seventeenth annual convention of the Association of American Agricultural Colleges and Experiment Stations held at Washington, D. C., November 17-19, 1903, edited by A. C. TRUE, W. H. BEAL, and H. C. WHITE (*U. S. Dept. Agr., Office of Experiment Stations Bul. 142, pp. 196, dgms. 3*).—An account of this convention has already been given (E. S. R., 15, p. 322).

Bibliographia agronomica universalis, E. OTTAVI, A. MARESCALCHI, ET AL. (*Casale: Ottavi Bros., 1903, Nos. 2, pp. 57–128; 3, pp. 129–176; 4, pp. 177–264*).—This is a continuation of the bibliography previously noted (E. S. R., 15, p. 418). The 4 numbers published contain 2,094 titles. An authors' index is appended to number 4.

A model farm, W. J. SPILLMAN (*U. S. Dept. Agr. Yearbook 1903, pp. 363–370, pls. 2*).—This is an account of the management of a 15-acre farm in southeastern Pennsylvania. The farm raises all the roughage for 30 head of stock, 17 of which are milch cows. During the first 7 years that the farm was in possession of the present owner it paid a mortgage of $7,200. The author concludes that the most important lesson to be learned from the achievements of this farmer is that by applying such methods as were used, it is possible to cause land to yield twice or three times as much as the present average from what are considered good methods.

"The most important single feature of this farm, aside from the remarkably systematic way in which it is conducted, is the manner of handling the manure. The fact that the stock are all stabled the year round makes it possible to save all the manure, both liquid and solid, and apply it to the land. Again, the fact that it is applied daily, as produced, insures that any leaching by rains shall carry the leached materials into the soil, where it is wanted. How much plant food is lost from fermentation after the manure is spread on the fields is not known. But the remarkable yields of every portion of this farm would seem to indicate that this method of handling manure is highly satisfactory.

"That similar results as to yield of crops may be accomplished by the use of commercial fertilizers, combined with crops grown expressly for the production of humus, is shown by the experience of a number of farmers, particularly in the truck-growing districts. It may, therefore, prove possible to develop almost any type of farming to a point that will more than double present average yields if agricultural science continues to develop as rapidly during the next quarter of a century as it has during the last."

The nation's farm surplus, G. K. HOLMES (*U. S. Dept. Agr. Yearbook 1903, pp. 479–490*).—A statistical review of the export trade of the United States is summarized by the author as follows:

"The vast total of exports is composed mostly of cotton, grain and grain products, and meat and meat products, with places of much less although of large importance taken by tobacco, live animals, oil cake and oil-cake meal, fruits and nuts, and vegetable oils. With attention concentrated upon three or four, or at most upon all these eight classes of products as exports to the countries of the earth, it may be still further concentrated upon the United Kingdom as receiving one-half of all this country's exports of farm products, and, in a less degree, upon Germany, the recipient of one-sixth, all other countries being individually of minor importance in the general survey.

"So it becomes easy to find our principal competitors, which are, in meats and meat products, Australasia, Argentina, and Canada, and Denmark in bacon; in live animals, Argentina and Canada; in grain and grain products, Argentina, Russia, Canada, and

Roumania, and at times British India and Australasia; in tobacco, the Dutch East Indies; while in cotton the other countries of the earth have not yet produced a direct competitor of the upland varieties grown in this country."

Crop Reporter (*U. S. Dept. Agr., Bureau of Statistics Crop Reporter, vol. 6, Nos. 1, pp. 1–8; 2, pp. 9–16; 3, pp. 17–24*).—These numbers for May, June, and July, 1904, contain the usual statistical reports on the crops in the United States and foreign countries.

A reconnoissance of Samoa, F. Wohltmann (*Samoa Erkundung 1903. Berlin: Kolonial Wirtschaftliches Komitee, 1904, pp. VI+164, pls. 20, figs. 9, maps 2*).—A report is given of the investigations of the author on the climate, soils, and agricultural and other economic conditions of the German Samoan Islands. Particular attention is given to the agricultural conditions, the cultivation of cacao being described in considerable detail.

A chapter is devoted to the subject of plant diseases, and attention called to the desirability of treating many of the plants for the existing diseases and quarantine regulations against the introduction of additional pests.

Progress in agricultural education, 1903, A. C. True (*U. S. Dept. Agr., Office of Experiment Stations Rpt. 1903, pp. 571–634, pls. 24*).—This article treats of the educational work of the Department of Agriculture, the Office of Experiment Stations, and the Association of American Agricultural Colleges and Experiment Stations; including in the discussion a report on school gardens and a reprint of the report of the committee on methods of teaching agriculture (E. S. R., 15, p. 325).

The article also reviews the work being done by the agricultural colleges, secondary schools, and primary schools. In discussing the agricultural colleges particular attention is paid to the courses in rural engineering and rural economy, courses offered in the latter subject in European agricultural schools being included. New buildings at some of the stations are described. The article concludes with a reprint of a circular of the Office giving a selected list of books on nature study and elementary agriculture.

Agricultural economics as a subject of study in the agricultural college, K. L. Butterfield (*U. S. Dept. Agr., Office of Experiment Stations Rpt. 1903, pp. 713–718*).—The importance of agricultural economics as a subject of study is emphasized, and an outline is given for a short lecture course on this subject.

Instruction in agriculture in land-grant colleges and schools for colored persons, D. J. Crosby (*U. S. Dept. Agr., Office of Experiment Stations Rpt. 1903, pp. 719–740, pls. 7*).—Information on this subject is presented by States, and some general conclusions are drawn in regard to the character of the work and the needs of the institutions. An article on the methods and facilities for instruction at the Hampton Normal and Agricultural Institute, by C. L. Goodrich, is included.

Development of the text-book of agriculture in North America, L. H. Bailey (*U. S. Dept. Agr., Office of Experiment Stations Rpt. 1903, pp. 689–712*).—Comments are made on the principal agricultural text-books which have appeared in the United States, and a complete list of such text-books, arranged chronologically, and containing the table of contents in each instance is appended.

Farmers' institutes in the United States, J. Hamilton (*U. S. Dept. Agr., Office of Experiment Stations Rpt. 1903, pp. 635–687*).—This is a report on the farmers' institutes in the different States and Territories, with summarized statistics and a general discussion of the work as a whole.

The farmers' institutes, J. Hamilton (*U. S. Dept. Agr. Yearbook 1903, pp. 149–158*).—This treats in a general way of the development and present status of the farmers' institute movement in the United States.

Farmers' institutes (*Ann. Rpt. Missouri State Bd. Agr., 36 (1903), pp. 260–307, pls. 5, figs. 9*).—Abstracts of some of the lectures delivered before the meetings held in 1903.

Annual report of the Illinois Farmers' Institute, with reports of county farmers' institutes, 1903 (*Ann. Rpt. Illinois Farmers' Inst., 1903, pp. 366, pls. 24, maps 2*).

Twentieth annual report of the department of land records and agriculture, Bombay Presidency, for the year 1902–3 (*Dept. Land Records and Agr., Bombay Presidency, Rpt. 1902–3, pp. 23+LVI*).—In addition to administrative reports, this document contains data relating to rainfall, agricultural implements, water supply, and irrigation.

Utilization of waste products, J. L. WELLINGTON (*Amer. Inventor, 12 (1904), No. 9, p. 200*).—The utilization of slag, gas of blast furnaces, lumber and timber wastes, slaughterhouse and packinghouse wastes (blood, hoofs, bones, horns, meat scraps, etc.), rags, and wool grease ("suint") is discussed.

On the utilization of kitchen refuse in German cities, N. LANDBERG (*Landtmannen, 14 (1903), No. 36, pp. 561–566*).

NOTES.

Alabama College and Station.—I. S. McAdory, a graduate of the Alabama Polytechnic Institute, has been appointed assistant in veterinary science, vice W. L. Thornton, resigned to engage in stock raising in Alabama. T. B. Rivett, a graduate of the Ontario Agricultural College, Guelph, has been appointed assistant in horticulture at the station, vice H. O. Sargent, who resigned to engage in teaching agriculture in the Agricultural School of the First Congressional district, Jackson, Ala.

Alabama Agricultural and Mechanical College for Negroes.—G. H. C. Williams, a graduate of the Pennsylvania State College, has been appointed instructor in agriculture.

Arizona Station.—Henry B. Slade, formerly assistant chemist of the Nebraska Station and chemist of the Idaho Station, succeeds W. W. Skinner as associate chemist. Mr. Slade is expected to prosecute research work in connection with the date palm and other organic materials. A. J. McClatchie has retired from the position of agriculturist and horticulturist of the station to his old home in California. In addition to conducting his private business, he will undertake special investigations for the Bureau of Forestry of this Department.

Arkansas Station.—A department for dairying and animal husbandry has been added, with Prof. V. A. Hooper, of Toronto, Canada, in charge. The station, in connection with the State, has purchased five head of Brown Swiss cattle at Syracuse, N. Y., for this work, with equipments for cheese and butter making.

Connecticut State Station.—Walter Mulford, station forester, has been given a year's leave of absence for study abroad, and Austin F. Hawes has been appointed assistant forester, to serve during his absence. A. W. Ogden, for fourteen years chemist at the station, has resigned to accept a position in the Bureau of Chemistry of this Department, and will be located in New York City. I. A. Andrew has been appointed chemist in the station.

Connecticut College and Storrs Station.—F. H. Stoneburn, poultryman, has resigned to become director of the Columbia School of Poultry Culture at Waterville, N. Y. He entered upon his duties September 1.

Florida University and Station.—The station staff has been reorganized as follows: Andrew Sledd, president of the university and director of the station; Chas. M. Connor, vice-director and agriculturist; E. H. Sellards, formerly of Rutgers College, entomologist and geologist; F. M. Rolfs, formerly of the Colorado Station, horticulturist and botanist; Edward R. Flint, chemist. The station is planning to undertake quite extensive cooperative experiments with potato growers in the potato-growing district, in order to get conditions as nearly normal as possible. The statement in the last number of the Record that R. A. Lichtenthaeler had resigned, was an error; he retains his position as assistant chemist.

Illinois University and Station.—H. W. Mumford has begun a series of articles on the study of animal husbandry in the *School News and Practical Educator*. The series begins with the September number, and is intended for use later in the series of leaflets on elementary agriculture as supplementary reading in rural schools.

Iowa Station.—Louis G. Michael has been appointed agricultural chemist. C. E. Ellis has been appointed assistant agricultural chemist vice E. C. Myers.

Kansas College and Station.—R. J. Brock has resigned his membership on the board of regents and has been succeeded by Geo. S. Murphey, Manhattan, Kans. Dr. N. S. Mayo has resigned his position as professor of veterinary science in the college and veterinarian of the station to accept the position of vice-director of the Central Experiment Station of Cuba and chief of the division of animal industry. Dr. Mayo first went to the Kansas institution in 1890 and has been connected with it ever since, excepting four years—from 1897 to 1901—when he held a similar position in the Connecticut Agricultural College and Station. Michael F. Ahearn, a graduate of the Massachusetts Agricultural College of the class of 1904, has been appointed foreman of the greenhouses. Geo. F. Freeman, a graduate of the Alabama Polytechnic Institute in 1903, but recently instructor in botany in the Massachusetts Agricultural College, has been appointed assistant in botany in the college and station. The college is installing a system of waterworks of its own, including the necessary piping, pumping machinery, and an elevated tank with a capacity of 100,000 gal. The auditorium, with a seating capacity of 2,700, is nearing completion. An addition to the woodworking shops is in progress of construction and will add materially to the room for machinery and for classes in mechanical drawing.

Maine Station.—In cooperation with the Bureau of Animal Industry of this Department, the station has begun the erection of a poultry house 120 by 16 ft. This is to be an open curtain-front house of about the same capacity as the other two houses at the station. In addition to the enlargement of the breeding work for egg production that will be afforded by the new house, experiments to extend over a series of years upon the relation between floor space and egg production are to be undertaken.

Maryland College and Station.—The position of horticulturist of the college and station has been filled by the appointment of Wm. N. Hutt, recently of the Utah Station. He entered upon his duties about November 1. The title of the position of agriculturist has been changed to agronomist. E. P. Walls, a graduate of the Maryland Agricultural College, class of 1903, has been appointed assistant agronomist. He is attached to the station, and will devote all of his time to the investigations of his department.

Massachusetts Station.—George W. Patch has been appointed meteorological observer, vice F. F. Henshaw. Richard H. Robertson, assistant chemist, died September 9.

Michigan College and Station.—R. H. Pettit, entomologist, has also assumed the duties of botanist of the station, the move being in the direction to separate more fully the station work from that of the college. F. O. Foster, recently at the Oklahoma College and Station, and lately engaged in commercial dairying in Baltimore, has been appointed instructor in dairying, vice John Michels, who has gone to Wisconsin University to take a post-graduate course, giving special attention to dairy cattle.

Montana College and Station.—James Reid, president of the college, has resigned. He has been succeeded by Prof. James M. Hamilton, who comes to the college from the State University at Missoula, where he was vice-president and professor of psychology and history. James Dryden, formerly meteorologist and poultryman at the Utah Station, has accepted a position as clerk and poultryman at the station.

New York State Station.—N. O. Booth, recently horticulturist in the Washington College and Station, has returned to the above station as assistant horticulturist, vice V. A. Clark, who, as previously noted, has gone to the Arizona Station.

Pennsylvania College and Station.—The Bureau of Animal Industry of this Department has assigned $1,000 of the recent Congressional appropriation for investigations in the breeding and feeding of domestic animals, to the cooperative investigations with the respiration calorimeter, now in progress at the station. Plans have been made for an investigation upon the influence of age and individuality upon the metabolism of cattle, and two yearling steers, one a Polled Angus and one a Jersey,

have been purchased for use in the investigation, which is expected to extend over several years. J. A. Fries, first assistant in animal nutrition, has been given a year's leave of absence for study abroad. The position will be filled during his absence by W. W. Braman, formerly second assistant in animal nutrition, and R. E. Stallings, assistant chemist, will serve as second assistant in animal nutrition. The fellowships in agricultural chemistry and dairy husbandry have been discontinued.

South Carolina College and Station.—Dr. Louis A. Klein has been elected to succeed Dr. G. E. Nesom as chief of the veterinary division. F. C. Atkinson has been appointed assistant chemist.

Tennessee University and Station.—Dr. Brown Ayres, formerly dean and professor of physics at Tulane University, New Orleans, has succeeded Dr. Charles W. Dabney as president of the university. Samuel M. Bain, botanist of the university and station, has undertaken work in cooperation with the Bureau of Plant Industry of this Department in the breeding of varieties of cotton resistant to attacks of the boll-weevil. During Professor Bain's necessary absence in carrying on this work Samuel H. Essary has been appointed assistant botanist of the station and instructor in botany in the university. Henry H. Hampton, assistant chemist of the station, has been succeeded by Walter H. Brown.

Virginia Station.—The station staff was reorganized the past summer, as follows: Andrew M. Soule has been appointed director; Harvey L. Price, horticulturist; William D. Saunders, dairy husbandman; Meade Ferguson, bacteriologist; John G. Ferneyhough, veterinarian; John R. Fain, agronomist; William A. P. Moncure, assistant mycologist; Phares O. Vanatter, field experiments; Walter Ellett, assistant chemist; Arthur P. Spencer, assistant in animal husbandry; Ellison A. Smyth, consulting biologist; David O. Nourse, consulting agrononomist; Thomas L. Watson, consulting geologist; Clement E. Craig, foreman of the field experiments. The work of the station will be specialized much more in the future than in the past and the working force more than doubled. An extensive system of field investigations will be undertaken. The department of field experiments will conduct the field work proper. The chemical and soil work will be undertaken by the department of chemistry. A forty-acre field has been laid out for this work, and extensive plantings made this fall. Special attention will be given to the department of animal husbandry, and the plans are now on foot to organize extensive feeding experiments with beef and dairy cattle, and swine. The college maintains about 300 head of live stock, a large percentage of which are pure-bred animals, there being choice representatives of three of the principal beef and dairy breeds. The dairy department will also undertake some special lines of investigation on pasteurized milk at an early date, while studies on soil bacteria will be undertaken by the bacteriologist. The work on cider making and the chemistry of fruits will be continued.

Wyoming Station.—F. E. Hepner, of South Dakota, has been appointed research chemist of the station. He began work October 1. The plans of work for the year in chemistry include water and forage plant analyses and digestion experiments with high-altitude stock foods. E. E. Nelson, assistant in horticulture and agrostology, resigned his position, to take effect October 1. B. P. Fleming, irrigation engineer of the station, has resigned his position in order to continue his studies at Cornell University.

United States Department of Agriculture.—Dr. R. E. B. McKenney, assistant physiologist in the Bureau of Plant Industry, who has been making a special study of the mosaic disease of tobacco, has resigned to accept a position with a firm doing business at Panama.

Dr. Ernst A. Bessey, who has been abroad for over two years, returned in October. While abroad he traveled in Russia, the Caucasus, Turkestan, and Algeria for this Department. He spent some time in study in the Universities of Halle and Munich, finishing his work for the doctorate in Halle last spring. He has been appointed in

the Office of Vegetable Pathological and Physiological Investigation, of the Bureau of Plant Industry, to make a thorough study of diseases of crops caused by nematodes.

Thomas H. Kearney, of the Bureau of Plant Industry, has gone to North Africa and other Mediterranean coast regions for the purpose of securing new seeds and plants adapted to the southwest. He will make a special study of the date palm and plan for new introductions of this fruit. Alkali-resistant forage crops will also be studied, and seeds of new and promising kinds will be collected for testing in this country.

W. P. Corsa, assistant pomologist in the Division of Pomology for the past 14 years, died September 3.

At the International Engineering Congress at St. Louis October 3 to 8, Elwood Mead, of this Office, was selected to present one of the four papers on irrigation, the other three papers being presented by foreign representatives. The subject of Mr. Mead's paper was Irrigation in the United States, and dealt with the development and present scope of irrigation, the engineering aspects, cheapening of construction, the reform of State laws, National legislation, and National and State investigation relating to irrigation.

County Experiment Stations.—In the September issue of the *Iowa Agriculturist* an account is given of the movement in that State toward the establishment of county experiment stations at the county poor farms. The purpose of these experiment stations is to answer some of the local county problems. The work undertaken at the station first established was to grow side by side 30 varieties of corn obtained from farmers in different parts of the county. The yields of these varieties varied from 15 to 55 bu. of grain per acre, thus bringing the fact home to farmers that there is a great difference in the value of the seed corn grown by different farmers in the same locality. This result opens up a vast number of similar problems with other crops. The first of these stations was established in Sioux County two years ago, the board of supervisors granting the money necessary to carry on the experiments. Since then Story, Marshall, Adams, and Pocahontas counties have established similar stations. The writer points out that there are five or six distinct soil types in Iowa, and that therefore tests of varieties of roots, grains, and grasses at the station on one type of soils may not be applicable in many other portions of the State. This is where the county experiment stations will come in investigating these local problems.

Wallace's Farmer, discussing the same subject, states that "the agricultural college cooperates with these various counties to the extent of sending a man to the farm to direct the method of preparation, to lay out the ground, and to teach the man in charge how to keep the correct data and thus furnish exact information that will be of value . . . Incidentally, the poor farm in counties where this method has been adopted becomes a center of great public interest. It is a favorite place for picnics during the growing season, where the farmers can see for themselves just how these experiments are coming on."

School of Forestry in Wales.—A conference of delegates appointed by the Welsh county councils to discuss the question of afforestation in the principality was held at Swansea on September 7. According to a brief account of this in *Nature*, Sir Charles Philipps, who presided, remarked that there was in Wales an enormous area which could be profitably afforested. It was necessary that professors of the subject should be appointed at the universities and that practical demonstration areas should be set apart. The view was expressed, in course of discussion, that the establishment of a central school of forestry for Wales was of the utmost importance, and that such a school would become self-supporting after a few years. It was at length resolved that the members should urge on their respective councils the great importance of the study and practical application of forestry by providing lectures to be given at suitable centers and bursaries, enabling students to attend these lectures; also that a central school of forestry be established with example plants of

three or more acres and demonstration areas of suitable extent, and that the necessary expense be defrayed by the county councils on the basis of their respective ratable values, the whole amount now asked for not to exceed £5,000.

Agriculture in Union Academy.—A four-year agricultural course is now offered by Union Academy, Belleville, N. Y. This is done at the request of George and Wm. W. Mather, who, in 1901, gave Union Academy $10,000 for the support of a school of agriculture. The course in agriculture includes two terms each of instruction in drafting plans for farm buildings, entomology, soils and fertilizers, horticulture, plant life, economics of agriculture, animal husbandry, poultry keeping and zootechny, and one year of agriculture (agronomy). Lyman Carrier, who had charge of chemistry and agriculture in the Elyria, Ohio, High School last year, has been elected vice-principal of Union Academy, and will teach science and agriculture.

New Journal of Agricultural Science.—The prospectus has been issued of a *Journal of Agricultural Science*, the publication of which is to be commenced at Cambridge, England, with the beginning of the year. The new journal will be edited by Messrs. T. H. Middleton, T. B. Wood, R. H. Biffin, and A. D. Hall, in consultation with W. Bateson, J. R. Campbell, and W. Somerville. The cooperation of a long list of gentlemen engaged in work in agricultural science has been promised.

The prospectus points out that there are now about 25 agricultural colleges in England, the larger number of which have been established during the past decade. Many of these institutions are equipped with permanent laboratories and experimental farms, and are beginning to devote their attention to definite scientific work in chemistry, botany, and other sciences bearing on agriculture. At present there appears to be no way of getting the results of their scientific work before the proper audience. It is the purpose of the new journal to publish only distinctly scientific work in agricultural science, and it will not include the results of the ordinary trials of manures and varieties for demonstration or commercial purposes.

New Veterinary Journal.—The first number of a new veterinary journal, entitled *Western Veterinarian*, was issued in July. This journal is to be published quarterly as the official organ of the California State Veterinary Medical Association, as a continuation of the quarterly bulletin of that association. The purpose of the change of name and appearance is to admit of an enlargement of the scope of the journal. The *Western Veterinarian* will contain a record of the proceedings of the California Veterinary Medical Association, news items, and original articles relating to veterinary science and practice.

Miscellaneous.—The Higher Education Subcommittee of the Lancashire Education Committee has issued a series of circulars describing the provisions made in the county for instruction in agriculture. Full particulars are given of courses in agriculture to be carried out at the County Council Farm at Hutton and the Harris Institute at Preston, as well as in other parts of the county. At the Harris Institute the course extends over four years, and is intended to prepare young men for the practical work of farm life. The subcommittee has also made arrangements to consider applications from local committees, agricultural societies, and farmers' associations for courses of lectures by members of the staff of the Harris Institute.

We learn from *Nature* that the Indian Tea Association is contemplating the establishment of an experiment station in Assam. The scientific advisor of the association has explained his plan for the permanent location of his assistant in Assam, the provision of a laboratory for him, and the initiation of experiments in tea culture under his direct supervision and control. An offer has been made by the agents of the Scottish Assam Tea Company to provide a small bungalow and tea for experiment in the immediate neighborhood of the bungalow, and further land for experiments as required. This offer was accepted, and arrangements have been made for the erection of a laboratory.

J. D. Towar, formerly of the Michigan College and Station, has returned from South Australia, where since 1902 he has occupied the position of principal of the Roseworthy Agricultural College and professor of agriculture in that institution.

Dr. Robert Ostertag, a member of the faculty of the veterinary high school at Berlin, and the foremost authority on meat inspection in Germany, recently made a tour of this country for the purpose of becoming more thoroughly acquainted with the conditions which prevail here with regard to veterinary medicine and animal industry. Doctor Ostertag visited many of the larger abattoirs in our chief cities, inspected a number of our veterinary schools, stock farms, and dairy institutions. A very favorable impression was formed by Doctor Ostertag regarding the work of the Bureau of Animal Industry in eradicating sheep scab and dipping cattle for the destruction of ticks. Many of our veterinary schools were considered by him as still defective in their curricula, but two especially (Cornell and Pennsylvania) were referred to as furnishing high grade and satisfactory instruction in all respects. Doctor Ostertag considered that some of our dairy farms were equal or superior with respect to general management, sanitary conditions, etc., to any similar institutions in the world. The system of meat inspection instituted and maintained by the Bureau of Animal Industry was considered as exceedingly effective and satisfactory. While at Ames, Iowa, Doctor Ostertag investigated the course in animal husbandry offered at that institution, and was so well impressed with its efficiency that he has decided to establish a course as nearly like it as possible in the veterinary high school at Berlin.

The Very Rev. Samuel Reynolds Hole, Dean of Rochester, England, and widely known as a writer on roses, died at his home on August 24, in his 85th year. He was one of the originators of the National Rose Society of England, and has been its president since the establishment of that society in 1858. He is best known perhaps to horticulturists through his Book About Roses, How to Grow and Show Them, and his book published in 1899, entitled Our Gardens. The Book About Roses has gone through 19 editions.

B. M. Everhart, well known for his work in systematic mycology, died at his home in Westchester, Pa., September 22, 1904, in his 87th year.

Dr. F. Nobbe, since 1868 professor in the Forestry School and director of the Experiment Station for Plant Physiology in Tharand, retired from active duties with the beginning of October.

Earnest Shearer has been appointed lecturer on agriculture at the Pusa Imperial College, Bengal, India. References have previously been made to the establishment of this model agricultural college for India, with a farm of 1,300 acres.

We learn from *Science* that Alexander Lauder, senior demonstrator in chemistry in the University College of North Wales, Bangor, has been appointed lecturer in agricultural chemistry in the Edinburgh and East Scotland College of Agriculture.

A chair of agricultural mechanics has been established at the University of Göttingen, and Dr. Ludwig Prandtl has been appointed to the chair.

O

EXPERIMENT STATION RECORD.

VOL. XVI. NOVEMBER, 1904. No. 3.

The practical demonstration of the methods employed in certain lines of agricultural instruction and investigation, as carried out at the St. Louis Exposition, was a novel undertaking. It supplemented very effectually the combined exhibit of the American agricultural colleges and experiment stations in the Palace of Education, and illustrated the methods which have been worked out for important branches of work and which could not well be shown in the other exhibit. As these methods have been largely developed in this country and are essentially American in their details, a demonstration of them was desirable to a clear understanding of the American system of agricultural education and research. The fact that exercises in stock judging, grain judging, and the like were being carried on by classes of students from the agricultural colleges, under the direction of instructors in these subjects, added materially to the interest of the exhibit, and served to demonstrate the practical character of the methods.

Two sessions of this "School of Breeding, Feeding and Judging Live Stock, and of Breeding Field Crops" were held, each of two weeks' duration. The first session was from September 12 to 24, during the cattle show, and the second from October 3 to 15, during the show of sheep and swine. The sessions were held in the Live Stock Congress Hall. An arena 45 by 75 feet was arranged in elliptical form, surrounded by terraced seats sufficient to accommodate 1,100 people. The tardiness of the exposition management in making provision for this exhibit made it possible to hold only two periods instead of three as contemplated, and greatly interfered with the progress of the exercises during the first session. A pavilion was originally planned for these exercises, but this was abandoned by the exposition management, and quarters assigned in the Live Stock Congress Hall. A $2,300 refrigerating plant was installed in a room adjoining the arena, and this was stocked with meat for the judging work. A five-horsepower motor was also furnished for thrashing the crops of the breeding plats. The school was under the general charge of Prof. J. H. Shepperd, of North Dakota.

The plan followed was to have about twenty-five students from five different agricultural colleges present at each session, to act as classes

for the instructors to use in demonstrating their methods of teaching live-stock judging, dressing and curing meats, judging grain, making gluten, sponge and baking trials with flour, and in thrashing, grading, and milling wheat. Animals were slaughtered in the presence of students and demonstrations given of the cutting and curing of meats. Exercises in judging corn and small grains, and in placing rings of all of the market and breeding classes of cattle, sheep and swine, constituted the programme rendered from day to day.

Sessions of the school were held daily in the forenoon, afternoon, and evening. Moving pictures representing the active work of students in judging live stock, studying farm mechanics, judging corn, carrying out the exercises in agricultural engineering, and the work of plant and animal breeding, were thrown upon the screen at intervals during the day. Addresses upon various phases of plant and animal breeding, feeding, methods of instruction, and kindred subjects were also delivered throughout the four weeks of the school. Approximately fifty lectures were given during the two periods, and a total of fifty students from various institutions took part in the work of the school from time to time.

The exercises in judging live stock and grains and the demonstration of the methods employed in instruction proved to be of much interest and attracted good-sized crowds. The slaughtering and cooking trials especially attracted the attention of the stock breeders and exhibitors present, who followed the trials closely and seemed to take a deep interest in them. It was frequently pointed out by visitors that the experiment stations are singularly well fitted to conduct slaughter trials, in which animals which have ranked well on foot are submitted without favor or prejudice to the crucial on the block, since private exhibitors often hesitate to take the risk.

The demonstration of the methods employed in plant-breeding work at the experiment stations was quite complete. Matured plants of oats, wheat, barley, spelt, millet, and flax, and young corn plants were set in natural form as they appear in the plant nurseries in actual work, with about two-thirds the usual interspaces. They were shown in all stages, some with clipped borders, others partially culled out in selecting the better plants, and others with the final or choice plants only remaining, which were to be kept for seed. On other plats the plants were harvested and placed in their proper receptacles.

Specimen record books were displayed and forms of plant pedigrees as they are ordinarily kept were shown. All forms of plant records and labels used in experimental work were shown in position as they are used in this work, so that visitors were able to see the entire system which has been worked out for plant breeding. A thrashing machine for plant-breeding work, a fanning mill, electric bake oven, and a small patent roller test mill (used for determining the grade of flour which a

sample of wheat will produce) were also exhibited in active operation, and the chemical apparatus employed for fat extraction and the determination of nitrogen in corn-breeding work was also shown.

The plant-breeding work, as it turned out, furnished good material for display and enabled an interesting and attractive exhibit to be made. It was so arranged as to enable the crowd to obtain a good general idea of the methods in a few minutes, while those who chose to spend a longer time in making a more complete study of the exhibit were afforded opportunity to do so.

The attendance at the various exercises of this "school" ranged from 50 to 1,000 people at a session, varying with the attendance at the fair and with the condition of the weather. The practical exercises and demonstrations proved as a rule to be of greater interest than the more formal lectures and moving-picture displays. The inaccessibility of the place where the school was held undoubtedly affected the attendence.

The indications are that the school made a marked impression upon a considerable body of people, who gained through it a much clearer conception of the methods employed at the agricultural colleges and experiment stations than they had previously had or than could well have been given in any other way.

The comments upon the exhibit of the agricultural colleges and experiment stations as a whole have been most favorable and complimentary.

It was in no sense a "show" exhibit, but the materials comprising it were those in actual use for instruction and experimentation at our land-grant colleges and experiment stations, or those representing with as much realism as possible the practical results of research. It was undoubtedly the most successful exhibit which these institutions have yet made, and its location in the Palace of Education secured for the agricultural departments of the colleges and the experiment stations a recognition of their place among the great educational efforts of the nation. It impressed itself upon intelligent observers as a worthy and consistent exposition of certain features of education and research in the relations of science to agriculture and the mechanic arts.

Its success was attested by the comments of competent judges and real seekers after information, as well as by the awards granted by the several juries. Exclusive of those granted to collaborators, there were one hundred and thirty-five awards made to the exhibit, including twenty-four grand prizes, forty-one gold, thirty-five silver, and thirty-five bronze medals.

RECENT WORK IN AGRICULTURAL SCIENCE.

CHEMISTRY.

The action of water and saline solutions upon certain slightly soluble phosphates. F. K. CAMERON and L. A. HURST (*Jour. Amer. Chem. Soc., 26 (1904), No. 8, pp. 885–913*).—The methods used and the results obtained in a study of the action of varying proportions of water and of sodium nitrate and potassium chlorid and sulphate on phosphates of iron and aluminum, and of water, calcium chlorid and nitrate, and potassium chlorid and sodium nitrate on tricalcium phosphate are given.

The method used was as follows: "In the majority of cases the procedure employed was to weigh the solid phosphate into a bottle and then add 200 cc. of water or solution. . . . Eight-ounce sterilizer bottles, tightly closed with rubber stoppers, were found to be very convenient. The bottles were completely immersed in a constant temperature-bath which varied less than 1° C. during the experiment. In some cases the bottles were occasionally shaken by hand, but in others they were placed in a submerged rotating cradle, driven by an electric motor, and the contents thus kept constantly agitated. When the solutions had remained in the constant-temperature bath the desired length of time, the bottles were placed in an upright position for 24 hours, or longer, to permit the suspended solid particles to subside, as far as possible, and then the supernatant solutions were passed through filters. An aliquot part of the clear filtrate, usually 100 cc., was then titrated with a standard solution of potassium hydroxid free from carbonates, using phenolphthalein as indicator, to determine the 'acidity' of the solution. . . . The phosphoric acid was then precipitated, in the usual way, as phosphomolybdate, and estimated gravimetrically as magnesium pyrophosphate, or occasionally by titrating the yellow phosphomolybdate precipitate with a standard solution of alkali. In a few cases the dissolved phosphoric acid was present in such small quantities that it was found desirable to estimate it by a colorimetric method."

The results are summarized as follows: "It appears that the rate of action of water upon phosphates of iron and aluminum, or upon tricalcium phosphate is very slow, so that neither in this investigation nor probably in any yet recorded, have final equilibrium conditions been observed. Free acid accumulates in the solution and a portion of the corresponding base is precipitated. While the free phosphoric acid tends to increase the solubility of the phosphate, the base, even though in solution in correspondingly smaller amounts, exerts a greater effect in decreasing it. Therefore, the addition of increasing amounts of water produces a relatively smaller (though in actual amounts a larger) solution and decomposition of the phosphate. . . .

"The presence of potassium chlorid in the solution decreases the amount of phosphoric acid obtained from iron, aluminum, or calcium phosphate. It increases the amount of iron, aluminum, or calcium entering the solution. . . .

"Potassium sulphate, as previously observed by Lachowicz, increases the amount

of phosphoric acid entering the solution from iron phosphate, but decreases the amount entering the solution from aluminum phosphate.

"Sodium nitrate decreases the amount of phosphoric acid entering the solution from either iron or aluminum phosphate, but appears to slightly increase the amount yielded by calcium phosphate, while it greatly increases the amount of calcium yielded to the solution by the last-named substance. . . .

"With pure water in contact with the phosphates the acidity of the resulting solutions appears to be in the same direction as the concentration with respect to phosphoric acid, but no satisfactory correlation has been made between the two sets of determinations. In solutions of more soluble salts in contact with the phosphates, no generalization whatever seems justified. Potassium chlorid, potassium sulphate, and sodium nitrate all increase the acidity of solutions in contact with iron phosphate, while potassium chlorid and sodium nitrate decrease the amount of the phosphoric acid in the solution. No correlation of the acidity with the amounts of iron in the solution seems possible, although, as is shown by the solutions of potassium chlorid, the base in solution is increased.

"In contact with calcium phosphate, potassium chlorid, and sodium nitrate decreased the acidity of the solution instead of increasing it, as in the case of iron phosphate. In both cases, however, the amounts of calcium in the solutions decidedly increased, and in the case of sodium nitrate the phosphoric acid also.

"In so far as observations were made, an increase of temperature increased the decomposition of the solid phosphates in either water or salt solutions.

"Owing to the complexity of the reactions involved between the hydrolyzed products and the other solutes, and perhaps also to the fact that definite equilibrium conditions were not under observation, attempts to apply the mass law to the results have not been satisfactory. The hypothesis of electrolytic dissociation has, in many of the cases observed, failed to give a satisfactory explanation."

A new method of rendering soluble the phosphoric acid in crude phosphates, A. Ystgaard (*Teknisk Ugeblad, Christiania, 50 (1903), No. 34, pp. 329–332*).—Experiments were conducted by the author (see also E. S. R., 15, p. 1063) for the purpose of rendering soluble the phosphoric acid of crude phosphates (apatite) at a comparatively low temperature and without the aid of silica. The effort was made to replace the lime in the phosphate with magnesia in the form of carnallite (or carnallite and kieserite), by which method 80 to 90 per cent of the total phosphoric acid was rendered soluble in a 2 per cent citric-acid solution.

By using bone ash as phosphatic material, in the place of apatite, as in the earlier experiments, 96 to 98 per cent of the total phosphoric acid was rendered soluble in citric-acid solution.

In experiments on a larger scale, apatite, carnallite, and kieserite, in the proportions of 1:2:1 were found to furnish a product that melted at about 650° C. and hardened on cooling to a brittle mass that may be easily reduced to a fine powder. The composition of this fertilizer was found to be as follows: Total phosphoric acid, 20.71 per cent; citric-acid-soluble phosphoric acid, 15.23 per cent; chlorin, 16.47 per cent; lime, 9.92 per cent; magnesia, 10.20 per cent; potash, 6.85 per cent.

Comparative fertilizer trials with this fertilizer and basic phosphate for oats and peas showed the former to possess a considerably higher value than the latter. The yields obtained with the new phosphate were 123 of oats and 140 of peas, those obtained with basic phosphate being placed at 100.—F. W. WOLL.

Contribution to the knowledge of the action of sterile and fermenting organic matter on the solubility of the phosphoric acid of tricalcium phosphate, A. Stalström (*Centbl. Bakt. u. Par., 2. Abt., 11 (1904), p. 724; abs. in Chem. Ztg., 28 (1904), No. 45, Repert. No. 13, p. 158*).—Experiments are reported which show that organic substances, such as humus, sour milk, etc., when not sterilized, dissolve tricalcium phosphate.

Determination of phosphates in natural waters, A. T. LINCOLN and P. BARKER (*Jour. Amer. Chem. Soc., 26 (1904), No. 8, pp. 975–980*).—Satisfactory tests on water of a modification of Schreiner's method (E. S. R., 15, p. 444) in which a sufficient amount of phosphate solution of known strength is added to make the proportion of phosphoric acid approximately equal to that of silica are reported.

Are inorganic phosphates found in seeds and seedlings? E. SCHULZE and N. CASTORO (*Ztschr. Physiol. Chem., 41 (1904), No. 5, pp. 477–484*).—From studies of a number of sorts of seeds the conclusion was reached that the phosphorus compounds designed as a reserve material occur entirely or almost entirely in organic forms.

If the seedlings grow for a considerable time without light it appears that a part of the organic phosphorus is changed into inorganic forms. This change probably takes place to a very limited extent in the case of germination under normal conditions. In such cases lecithin should be mentioned as one of the compounds formed from phosphorus reserve materials. The phosphoric acid occurs in the same part of the seeds as the reserve protein, fat, and carbohydrates, and the fact that it increases or decreases with the reserve protein is regarded as more than accidental.

Potassium tetroxalate as a titrating reagent, O. KÜHLING (*Chem. Ztg., 28 (1904), Nos. 50, p. 596; 51, p. 612*).—A reply to G. Lunge's criticism of the author's method of preparing this substance (E. S. R., 15, p. 649).

The use of potassium tetroxalate as a titrating reagent, G. LUNGE (*Chem. Ztg., 28 (1904), No. 60, pp. 701, 702*).—A reply to criticisms by Kühling (noted above).

Potassium tetroxalate as a titrating reagent, O. KÜHLING (*Chem. Ztg., 28 (1904), No. 64, p. 752*).—A reply to Lunge's article noted above.

Dumas' method of determining nitrogen, A. LANDSIEDL (*Chem. Ztg., 28 (1904), pp. 643, 644; abs. in Chem. Centbl., 1904, II, No. 4, pp. 363, 364, fig. 1*).—An improved measuring tube for use in this method is described.

The volumetric determination of nitric nitrogen by means of ferrous sulphate, G. BAILHACHE (*Bul. Soc. Chim. Paris, 3. ser., 31 (1904), No. 14, pp. 843–846*).—The author describes his modification of the Pelouze method substituting ferrous sulphate for ferrous chlorid, operating in an atmosphere of carbon dioxid and titrating the unoxidized ferrous salt with potassium permanganate or bichromate. The author objects to Debourdeaux's modification of his method using a carbon dioxid apparatus and a refrigerator (E. S. R., 15, p. 747) as difficult of operation.

The estimation of ammonia in animal juices and organs, M. NENCKI and J. ZALESSKY (*Arch. Sci. Biol. [St. Petersburg], 9 (1901), pp. 322–336; Chem. Centbl., 1903, I, pp. 601, 602; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 7 (1904), No. 9, p. 554*).—A modification of the usual method is described.

The form in which nitrogen occurs in the proteid molecule, T. GÜMBEL (*Beitr. Chem. Physiol. u. Pathol., 5 (1904), No. 5–6, pp. 297–312*).—A critical study of W. Hausmann's[a] method of determining the amount of different kinds of nitrogen in protein is reported. This method depends on the cleavage of the protein with boiling concentrated hydrochloric acid; the estimation of the amid nitrogen by distillation with magnesia; the separation of the diamin or basic nitrogen by precipitation with phosphotungstic acid, and the estimation of the monamino nitrogen not separated by the magnesia and phosphotungstic acid.

The conclusion was reached that in the case of the amid nitrogen the results are very accurate, and that they are quite accurate in the case of the monamino nitrogen, while in the case of the diamino nitrogen they are accurate within 0.8 of a per cent, the values being generally too low.

Concerning the form in which nitrogen occurs in albumin, C. ROTHERA (*Beitr. Chem. Physiol. u. Pathol., 5 (1904), No. 9, pp. 442–448*).—Continuing work referred to above, Hausmann's method was further studied. The conclusion was

[a] Ztschr. Physiol. Chem., 27, p. 91; 29, p. 136.

reached that the amid nitrogen was derived from two portions of the proteid molecule and that the estimation of the quantities from the different sources would be of value. The author concluded further that melanin, at least the major portion, was not formed at the expense of the easily cleaved nitrogen (amid nitrogen). The distribution of nitrogen in ichthin and chitin was also studied.

Concerning the estimation of albumen and some other nitrogenous constituents of plants, N. Nedokutschajew (*Landw. Vers. Stat., 58 (1903), Nos. 3-4, pp. 275-280*).—The analytical data reported led the author to conclude that the unripe and ripe wheat grain contained proteids soluble in water, which are thoroughly coagulated only when warmed under a pressure of 1.5 atmospheres. When this was done no cleavage was noted which could affect analytical results.

In addition to the true proteids the wheat contained albumoses precipitated from a solution by saturation with zinc sulphate. Estimating proteids by heating to 112° C. and precipitating albumoses with zinc sulphate gives somewhat higher results than the Stutzer method. The grain in all stages of growth also contains an appreciable quantity of nitrogen in compounds which are precipitated with phosphotungstic acid. A small amount of xanthin bases is also precipitated.

The results of both quantitative and qualitative analyses warrant the conclusion, in the author's opinion, that the unripe grain contains a complicated mixture of crystallizable nutritious bodies. The diminution of these bodies as the grain ripens indicates that they play an important rôle in the formation of reserve proteids.

Volumetric determination of humus in soils by means of potassium permanganate, Ishcherekov (*Zhur. Opuitn. Agron. [Jour. Expt. Landw.], 5 (1904), No. 1, pp. 55-67*).—The author criticises the methods at present in use as either too complicated or inaccurate. The method proposed by him is as follows:

After the soil is well pulverized in an agate mortar a sample weighing 0.5 to 0.1 gm., according to the richness of the soil in humus, is placed in a flask of 250 to 300 cc. capacity; into the flask a standard solution of potassium permanganate ($\frac{1}{10}$ or $\frac{1}{5}$ normal) is next introduced in considerable excess, from 2 to $2\frac{1}{2}$ times as much as is necessary for the complete oxidation of the humus content (0.01 gm. of humus requires 9.72 cm. of $\frac{1}{5}$ normal potassium permanganate solution). Then 2 to 4 cc. of sulphuric acid are added, i. e., somewhat more than is necessary for the reaction. An amount of water equal to that of the potassium permanganate solution is also added to replace the water evaporated in the subsequent boiling. The flask is heated in an inclined position, bringing the contents to gentle boiling, which is maintained for 40 to 50 minutes. Then titrate with oxalic acid.

On the addition of the latter the characteristic color of the permanganate solution disappears first and then the brown oxid of manganese, but the black manganese peroxid sometimes dissolves with great difficulty. In that case an excess of oxalic acid is added, the liquid again brought to boiling, and the solution titrated back with potassium permanganate.

Assuming that all the oxygen given off by the potassium permanganate is used up for the oxidation of the humus it is easy to calculate the amount of carbon dioxid formed, from that the carbon of the humus, and then the humus itself.

The method was tested with satisfactory results (which are reported) on a variety of soils. The author in a number of cases collected the carbon dioxid formed in the oxidation by potassium permanganate and calculated therefrom the humus and obtained values which did not differ much from those given in the analyses.—P. FIREMAN.

Determination of humus by the chromic method, A. N. Sabanin (*Zhur. Opuitn. Agron. [Jour. Expt. Landw.], 4 (1903), No. 5, pp. 573-594*).—The author gives the results of parallel determinations of humus in 126 soils by the chromic method as carried out in the agricultural laboratory of the Moscow University, and by the

method of Gustavson. The author having adopted a number of modifications introduced by various chemists, carries out the chromic method as follows: 2.5 to 5 or more grams of the soil are treated with a 5 to 10 per cent solution of phosphoric acid, dried at 103 to 105° C., and then transferred to a flask of 250 cc. capacity by the aid of a mixture of 30 cc. of concentrated sulphuric acid and 20 cc. of water. Instead of potassium bichromate crystallized chromic acid (CrO_3) is used to the amount of 7 to 9 gm.

It is quite necessary to regulate the oxidation. In 10 seconds 18 to 20 gas bubbles should pass through the potash bulbs filled with concentrated sulphuric acid for the absorption of the water. The product of the oxidation and the water vapor pass first through a Classen cooling apparatus and then, in order to retain the vapor of hydrofluoric and hydrochloric acid, through a U containing a bright fine iron wire spiral. The carbon dioxid is absorbed in the usual way.

The results obtained by this method were somewhat lower than those obtained by Gustavson's method. This difference is due, according to the author, to the fact that there is in the soils ready-formed carbon dioxid which Gustavson does not remove by treatment with phosphoric acid before the combustion. By using chromic acid in place of potassium bichromate the author avoids some sources of error connected with the formation of chrome alum in the latter case.—P. FIREMAN.

On the question of the acetic-acid extract of soils, D. N. PRIANISHNIKOV (*Zhur. Opuitn. Agron.* [*Jour. Expt. Landw.*], *5* (*1904*), *No. 2, pp. 197–200; abs. in Chem. Centbl., 1904, II, No. 6, p. 554*).—The author believes that the results obtained by extracting soils with acetic acid does not furnish a reliable means of judging of their fertilizer requirements. Account must be taken of the insolubility of the reverted phosphoric acid in the solvent. Moreover, the iron phosphate which is insoluble in acetic acid furnishes a fairly assimilable source of phosphoric acid for plants as Gedroitz has shown (E. S. R., 15, p. 549) and the author has confirmed in sand cultures with oats, millet, and lupines in 1900 and 1903.

On the reaction of lard from cottonseed meal-fed hogs, with Halphen's reagent, E. FULMER (*Jour. Amer. Chem. Soc., 26* (*1904*), *No. 7, pp. 837–851*).—The effect of cotton-seed oil upon the character of lard was studied. The minimum amount consumed during the experimental period was 1.8 lbs. per 100 lbs. of weight, and the maximum amount 75 lbs. Samples of fat were in every case taken from the kidney, jowl, back, and intestines, and in many cases from the belly also.

"All lard samples gave a distinct and, in some cases, a very strong coloration when treated with Halphen's reagent. The coloration equivalent, expressed in percentages of cotton-seed oil, ranged from 0.4 to 15 per cent. In general, the greatest degree of coloration was found in kidney fat lard, and the least in intestinal fat lard. . . .

"If the degree of coloration with Halphen's reagent is to be expressed in terms of percentage of cotton-seed oil, the kind of oil used for comparison, and the conditions under which the comparison is made should be stated, because different oils respond with unequal intensity, and the depth of color increases after cooling. When the color-producing substance is once deposited in the fat of hogs, it is exceedingly persistent. . . .

"While the evidence is somewhat conflicting we are rather unwillingly led to the conclusion that probably the color-producing principles are separated from the cotton-seed oil by metabolic processes, and that the effects of metabolism are so profound that its final products, if they find their way into the fat, do ~~not~~ modify it in any important degree."

Identification of boric acid in meat, A. REINSCH (*Ber. Untersuch., Altona, 1903, pp. 10, 11; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 7* (*1904*), *No. 9, p. 555*).

Concerning a new method of estimating sugar in chocolate, A. STEINMANN (*Ztschr. Oeffentl. Chem., 9* (*1903*), *pp. 239–249, 261–269; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 7* (*1904*), *No. 9, pp. 560–562*).

Estimating sugar in cocoa products, JESERICH (*Ztschr. Oeffentl. Chem., 9 (1903), pp. 452–454; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 7 (1904), No. 9, p. 562*).

Examining and judging cocoa products, FILSINGER (*Ztschr. Oeffentl. Chem., 9 (1903), p. 7; abs. in Hyg. Rundschau, 14 (1904), No. 3, pp. 146, 147*).—Analytical data are reported and discussed with special reference to the examination of chocolate and other cocoa products.

Note on the identification of Bombay mace in powdered mace, W. BUSSE (*Ztschr. Untersuch. Nahr. u. Genussmtl., 7 (1904), No. 10, pp. 590, 591*).—The author considers his method reliable.

Note on the examination of molasses feeds for fat and sugar, D. J. HISSINK (*Landw. Vers. Stat., 60 (1904), No. 1–2, pp. 125–134*).—Different methods are compared and discussed.

The preparation of crude fiber from plant fibers containing lignin by means of sodium superoxid, A. DUSCHETSCHNIK (*Zhur. Russ. Fiz. Khim. Obshch., 35 (1903), No. 12, Protok., pp. 159, 160; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 7 (1904), No. 10, p. 631*).—Using sodium superoxid mixed with magnesium sulphate, the author obtained very favorable results in separating crude fiber from spruce wood and from jute. The method of procedure is described.

The estimation of starch in substances containing pentosan, S. WEISER and A. ZAITSCHEK (*Landw. Vers. Stat., 58 (1903), No. 3–4, pp. 219–231*).—The experimental data which are reported led the author to conclude that in the analyses of feeding stuffs pentosans should be estimated as well as starch if accurate results are desired.

The true starch content can be calculated, he points out, if the amount of copper precipitated by the reducing bodies formed from pentosans is deducted from the amount precipitated by the total reducing bodies obtained in the usual methods of analyses. Estimating the starch and pentosan is a decided advantage, as it lessens the amount of nitrogen-free extract, and so makes for accuracy.

Methods for the quantitative chemical analysis of the brain and cord, W. KOCH (*Amer. Jour. Physiol., 11 (1904), No. 3, pp. 303–329*).—Analyses of white and gray matter of human brain with special reference to the distribution of phosphorus and nitrogen are reported, the analyses being illustrative of the analytical methods described.

Concerning the solution and swelling of colloids, K. SPIRO (*Beitr. Chem. Physiol. u. Pathol., 5 (1904), No. 5–6, pp. 276–296*).—Studies of gelatin by methods of physical chemistry are reported and discussed.

Fourth annual report of the agricultural chemist for the year 1902–1903, A. LEHMANN (*Dept. Agr. Mysore State, Rpt. Agr. Chem., 1902–3, pp. 27*).—This report "contains results of plat experiments, [and] gives the composition of various soils, fertilizers, coffees, oils, and water analyzed during the year. It gives also a few notes on entomology and a short report on a rice huller."

A rapid accurate method for the volumetric estimation of carbon dioxid, T. MACARA (*Analyst, 29 (1904), No. 338, pp. 152, 153, fig. 1*).—A method based upon the fact that barium carbonate behaves like an alkali toward methyl orange is described. The carbon dioxid evolved in the usual way is collected in a barium hydrate solution, the barium carbonate formed being titrated with standard acid, using methyl orange as an indicator.

The filtration and incineration of slimy precipitates, M. DITTRICH (*Ber. Deut. Chem. Gesell., 37 (1904), pp. 1840–1842; abs. in Chem. Centbl., 1904, I, No. 22, p. 1501*).—The filtration and incineration of such precipitates are facilitated by shaking them up with water and filter paper until the latter is reduced to a fine pulp.

Note on the use of hydrazin sulphate in eudiometric analysis, J. DE GIRARD and A. DE SAPORTA (*Bul. Soc. Chim. Paris, 3. ser., 31 (1904), No. 15, pp. 905–907*).

Chemical technology and analysis of oils, fats, and waxes, J. LEWKOWITSCH (*London: Macmillan & Co., Ltd., 1904, 3. ed. enl., vols. 1, pp. 427, figs. 53; 2, pp. 709, figs. 35*).

On the new sedimentation apparatus devised by Vinassa for soil analysis, with comparative experiments, C. BORTOLOTTI (*Staz. Sper. Agr. Ital., 37 (1904), pp. 358–365; abs. in Chem. Centbl., 1904, II, No. 7, p. 614*).—Comparative tests of this apparatus and that of Appiani, which is constructed on the same principle, gave results favoring the new apparatus, especially as regards saving of time and material.

BOTANY.

The influence of nutrition on the sex of diœcious plants, E. LAURENT (*Compt. Rend. Acad. Sci. Paris, 137 (1903), No. 18, pp. 689–692; abs. in Bot. Centbl., 95 (1904), No. 12, p. 297*).—Experiments have been conducted for 7 years with spinach, hemp, etc., to determine the influence of various fertilizers on the embryo of the plants.

An excess of nitrogen or lime gave an increase in staminate plants, while potash and phosphoric acid increased the number of pistillate ones. Seed produced with an excess of nitrogen gave plants in which pistillate forms predominated, and among those producing monœcious plants most of the flowers were pistillate. With an excess of potash, phosphoric acid, and lime a contrary result was produced.

The stimulating effect of some metallic salts on the growth of plants, M. KANDÁ (*Jour. Col. Sci. Imp. Univ. Tokyo, 19 (1904), Art. 13, pp. 47; abs. in Bot. Centbl., 95 (1904), No. 20, p. 538*).—Copper sulphate in very dilute solutions, which were injurious when applied to pea seedlings in water cultures, when added to humus soils proved not only not injurious to the plants, but exerted a stimulating influence upon their growth.

Zinc sulphate used in a similar way had the same effect. When used in a strength of solution of 0.28 per cent, vetches, which were watered 3 times a week, were decidedly stimulated in their growth. Sodium chlorid, when used in strengths of 0.0002 to 0.002 per cent, was stimulating to plant growth, but when used as concentrated as 0.02 per cent it proved destructive.

Native economic plants of the Transvaal, J. B. DAVY (*Transvaal Agr. Jour., 2 (1904), No. 7, pp. 278–313*).—Notes are given on some of the economic plants which are native and introduced in the Transvaal, attention being called to a number of plants which are reputed as being poisonous, species of troublesome weeds, etc. Brief notes are given on diseases of plants which have been observed, and suggestions given for their prevention. An attempt is made to enumerate some of the more abundant species of plants, giving their vernacular and botanical names.

Commercial plants of Germany, F. W. NEGER (*Die Handelspflanzen Deutschlands, Vienna and Leipzig: A. Hartleben; rev. in Ztschr. Untersuch. Nahr. u. Genussmtl., 7 (1904), No. 10, p. 637*).

The rôle of alkaloids as a source of nitrogen for plants, L. LUTZ, (*Bul. Soc. Bot. France, 50 (1903), pp. 118–128; abs. in Bot. Centbl., 95 (1904), No. 11, pp. 278, 279*).—Investigations by the author have shown that plants, and especially fungi, when given various alkaloids could utilize them as sources of nitrogen, but a much better growth of plant and greater assimilation of nitrogen resulted when an assimilable form of nitrogen, such as ammoniacal nitrogen, was added to the culture media. This phenomenon was explained by Clautriau as possibly due to the necessity of the fungus making a considerable growth before it was able to utilize the alkaloid.

To test this hypothesis experiments were conducted with various fungi in which they were grown first in culture media containing a nitrogen salt, after which the plants were transferred to a second solution, the only nitrogen of which was in an alkaloid compound.

In every case there was some nitrogen assimilation from the alkaloidal solution, but it was never as great as when the 2 forms of nitrogen were present. It is believed

that when the fungus continued to grow in a second medium and to assimilate the alkaloids it was due to a certain extent at least to the presence of ammoniacal nitrogen in the mycelium enabling the fungus to utilize the nitrogen present in the alkaloid.

From this the author concludes that alkaloids secreted by plants are not to be considered as reserve substances but only as by-products of the plant, and are utilized only under special conditions.

Notes on assimilation by chlorophyll, C. Bernard (*Bot. Centbl. Beihefte, 16 (1904), No. 1, pp. 36–52, figs. 2; abs. in Bot. Centbl., 95 (1904), No. 21, pp. 563, 564*).—Following the methods of Friedel and Macchiati (E. S. R., 14, p. 1047), the author has endeavored to ascertain the power of chlorophyll to carry on photosynthesis when removed from the living plant. Experiments are reported with spinach and various aquatic plants, the tests being made by improved methods, but in every case negative results were obtained. The author concludes that the hypothesis of enzymic action by chlorophyll, as far as his experiments go, is not demonstrated.

The effect of temperature on carbon-dioxid assimilation, Gabrielle L. C. Matthaei (*Proc. Roy. Soc. [London], 72 (1903), No. 483, pp. 355, 356*).—A summary is given of investigations made with cherry-laurel leaves to determine the carbon-dioxid assimilation as affected by temperatures.

These leaves were subjected to temperatures ranging from −6 to 45° C. At each temperature illumination at different intensities was required in order to make certain that the amount of assimilation was not limited by insufficient lighting. When a leaf is exposed to light of high intensity the excess of radiation raises the temperature of the leaf above that indicated by an adjacent thermometer, and under some of the conditions of the experiments this excess amounted to as much as 10° C.

The various precautions adopted to eliminate error in experiments are described, and after taking all factors into consideration it was found that the respiration becomes determinable at −6° C. and then rises rapidly with the higher temperatures up to 38° C. At temperatures above this point the leaf is not capable of maintaining its high rate of assimilation for any length of time, so that the values obtained for successive hourly estimation of the same leaf form a rapidly declining series. The higher the temperature the shorter the duration of the period of maximum assimilation and it becomes impossible to obtain the maximum values at temperatures close to 45° C., which was the fatal temperature for the leaves experimented with. The optimum temperature for assimilation was 38° C.

Some results of cross pollination, Leclerc du Sablon (*Compt. Rend. Acad. Sci. Paris, 137 (1903), No. 26, pp. 1298, 1299; abs. in Bot. Centbl., 95 (1904), No. 8, p. 180*).—The effect on the carbohydrates in the pericarp of a number of cucurbit species in which the pollen was transferred from one species to another is shown. The author transferred the pollen from melons to melons, from melons to cucumbers, from cucumbers to melons, and from cucumbers to cucumbers.

The fruits produced were analyzed at maturity, and while there was no visible effect due to the cross pollination, yet the melon which resulted from the stimulus of the cucumber pollen did not possess the ordinary sweet taste of melons. An analysis of the pericarp showed that the influence of the cucumber pollen had diminished the sugar content from 24.3 per cent to 5.8 per cent. The contrary cross of melon pollen on cucumber did not result in any increase of sugar in the cucumber. Cross pollination of different varieties of squash are described, in which there was no modification of a morphological character, but a decided diminution of the carbohydrates.

FERMENTATION—BACTERIOLOGY.

A note on the action of radium on micro-organisms, A. B. GREEN (*Proc. Roy. Soc. [London], 73 (1904), No. 494, pp. 375–381, pl. 1*).—Experiments to test the effect of radium bromid on various organisms are reported. The investigations were made to determine the germicidal action of the radium emanations, and in the second place to determine whether the micro-organisms themselves became radioactive.

Fresh calf vaccine which contained 4 species of extraneous bacteria, and about 2 dozen species of miscellaneous bacteria were subjected to the action of radium bromid, and it was found that the radium exerted a marked germicidal action on the specific and extraneous micro-organisms of vaccine, as well as upon the other organisms when exposed to radium at a distance varying from 1 to 2 mm.

The details of the experiments are given at some length, and it was found that while the micro-organisms which had been killed by exposure to radium became radio-active it was not ascertained whether the living ones could exhibit that property.

Investigations on the ferments causing depreciation of wines, P. MAZÉ and P. PACOTTET (*Rev. Vit., 21 (1904), Nos. 541, pp. 461–563; 542, pp. 489–494; 543, pp. 517–519; 544, pp. 545–548, pl. 1, figs. 6*).—A brief summary is given of the work of a number of prominent investigators on the ferments which cause the deterioration of wines, after which the methods of isolation and study are described. A number of the more common forms are figured and described and their effect on various wines and other media shown.

The effect of aniline colors on invertin, S. S. MERESHKOWSKY (*Centbl. Bakt. u. Par., 2. Abt., 11 (1903), No. 2, pp. 33–45*).—In order to determine the effect of various coloring materials on ferments, the author conducted a series of experiments in which the effect of fuchsin, Congo red, and safranin on invertin was investigated.

The experiments are reported in detail and it was found that the anilin coloring materials undoubtedly had a direct action on invertin in proportion to the molecular structure of the coloring matter. It appeared that invertin in the presence of anilin colors of known concentration is not destroyed, but there is set up an unstable compound that acts indifferently toward cane sugar. If, however, a fresh solution of sugar be added to the mixture the former compound is broken up and part or all of the invertin is liberated.

The preparation of nutrient media for the cultivation of bacteria, G. HESSE (*Ztschr. Hyg. u. Infectionskrank., 46 (1904), No. 1, pp. 1–22*).—As the result of an elaborate study of this subject, during which various bacteria were grown on different media contained in different kinds of glass, the author recommends that in sterilizing culture media glassware be used which does not yield alkali.

For determining the reaction of nutrient media phenolphthalein is considered a much more delicate reagent than litmus paper. The author believes that this is the only method by which the alkali content of a culture can be accurately determined as well as the proper amount to be added to any particular culture. The proper reaction of the medium should be brought about while the material is at a temperature of 40° C.

A method of cultivating anaerobic bacteria, J. BORDET (*Ann. Inst. Pasteur, 18 (1904), No. 5, pp. 332–336, figs. 2*).—Most methods proposed for the cultivation of anaerobic bacteria suffer from the disadvantage of requiring complicated apparatus. The author attempted to devise a simplified method. The test tubes and flasks are placed in bell jars from which the air is exhausted by the use of air pump and pyrogallate of potash. The technical cultural details are carefully described. The method has given good results with the tetanus bacillus.

Mucin as a bacterial product, L. F. Rettger (*Studies Rockefeller Inst. Med. Research, 1 (1904), Art. 16; reprinted from Jour. Med. Research, 10 (1903), No. 1, pp. 101–108*).—The possibility of the occurrence of mucin as a bacterial product was suggested to the author and a series of investigations reported in which *Bacterium subriscosum* was grown in various media. After growing for some time the substance formed was separated by precipitation and filtration and subjected to analysis.

The organism grew rapidly in 1 to 2 per cent peptone solutions, although the amount of mucin formed was considerably less than when growth occurred in beef bouillon or in milk. It was found that the production of mucin did not depend upon the presence of carbohydrate material in the medium. The addition of varying quantities of dextrose, levulose, lactose, etc., to the bouillon did not perceptibly increase the amount of mucin formed.

Further investigations showed that the production of mucin or a mucin-like substance is not limited to a single species of bacteria, but is a property possessed by many, if not all, though in most cases the quantity of mucin formed was so small as to be scarcely perceptible. There was found evidence that the process of mucin production by bacteria is not a direct one and there is presumably formed an intermediate body called a pseudomucin. As development goes on this peculiar substance becomes transformed into the more soluble form of mucin. All attempts to isolate this intermediate body by cultural methods have thus far been unsuccessful.

The agglutination affinities of related bacteria parasitic in different hosts, T. Smith and A. L. Reagh (*Studies Rockefeller Inst. Med. Research, 1 (1904), Art. 12; reprinted from Jour. Med. Research, 9 (1903), No. 3, pp. 270–300, dgms. 3*).—The fact that there are races of bacteria indistinguishable among themselves except in inconstant cultural details has led to a number of studies to determine their affinities. In the present paper the authors give a history of the cultural tests made with hog-cholera organisms, several varieties of *Bacillus coli communis*, typhoid bacillus, *B. icteroides*, etc., in which they conclude that there exists agglutination relationships between the pathogenic groups of bacteria, which ferment dextrose, as given in their experiments.

The agglutinative characters are probably modified when the bacillus becomes parasitic on different hosts. Close agglutinative affinities may be predicted from close biological and pathogenic relationships. Minor cultural differences do not exclude agglutinative affinities.

It appears that closely related bacteria vegetating on mucus membranes may vary considerably in their agglutinative relationships, differing in this regard from species whose varieties or races are more homogeneous. The specific agglutinative properties of the different races of bacteria studied are described. A bibliography of about 20 publications relating to the subject completes the paper.

The nonidentity of agglutinins acting upon the flagella and upon the body of bacteria, T. Smith and A. L. Reagh (*Studies Rockefeller Inst. Med. Research, 1 (1904), Art. 18; reprinted from Jour. Med. Research, 10 (1903), No. 1, pp. 89–100*).—A study of the agglutinins of the hog-cholera bacillus and other organisms has led to the conclusion that the nonmotile race and the motile races manifest a close affinity toward each other in the presence of immune agglutinins.

This affinity makes it possible to differentiate the agglutinins of motile bacilli into flagellar and body agglutinins. The assumption of 2 agglutinins, it is said, will probably serve to clear up various discrepancies in agglutination tests.

The bacilli of the root tubercles of red clover, L. Petri (*Nuovo Gior. Bot. Ital., n. ser., 10 (1903), p. 272; abs. in Centbl. Bakt. u. Par., 2. Abt., 11 (1903), No. 10–11, pp. 347, 348*).—It is said that from young root tubercles of red clover at the time of the most active growth of the host plant, the author isolated an organism which he has cultivated upon various media and reported the cultural characteristics. The

bacteria are characterized by a capsule which surrounds them, and while very abundant in the young root tubercles do not seem to occur in the soil surrounding them. The affinities of the organism are described and the author gives it the name *Bacillus capsulatus trifolii*, n. var.

The bacterial flora of cultivated soils, L. HILTNER and K. STÖRMER (*Mitt. Deut. Landw. Gesell.*, *18* (*1903*), *Nos. 48*, *pp. 266–268; 49*, *pp. 270, 271*).—This is a summary of a longer article,[a] discussing especially methods used in the bacteriological examination of soils, the causes of the increased productiveness of soils following treatment with carbon bisulphid, and the character and growth of micro-organisms in fallow soil.

The influence of carbohydrates on the gas exchange of yeast, E. KOLLEGORSKY and O. ZASSOUCHINE (*Centbl. Bakt. u. Par.*, *2. Abt.*, *11* (*1903*), *No. 3*, *pp. 95–105*).—The results of experiments in determining the effect of various carbohydrates on the respiration of yeast are given. The authors added to the culture media glucose, fructose, maltose, saccharose, raffinose, various alcohols, glycerin, and mannite, cultivating in the media *Saccharomyces cerevisiæ I* and *Schizosaccharomyces pombe*. The experiment shows that the proportion between the carbon dioxid and oxygen varied with the different carbohydrates added to the culture media. The details of the investigation are given in tabular form.

A study of the proteolytic enzyms of malt, R. VANDERVAEREN (*Rev. Gén. Agron.* [*Louvain*], *12* (*1903*), *No. 12*, *pp. 512–514*).—A brief note of experiments carried on by Weis at the Carlsberg-Copenhagen Laboratory of Physiology.

On the chemical nature of the oxydases, K. ASO (*Bul. Col. Agr. Tokyo, Imp. Univ.*, *5* (*1903*), *No. 4*, *pp. 481–489*).—A critical review is given of various opinions regarding the chemical nature of oxydases and the results of the author's investigations with buds of the potato and other plants from which the conclusion is drawn that it is very improbable that the oxydase and peroxidase of plant juice are organic peroxids. In the experiments reported the liberation of iodin by plant juices was found to be due to traces of nitrites in the plants, and it is believed that these are present in other plant juices.

Studies of the proteolytic enzyms of germinating barley, F. WEIS (*Copenhagen: 1902*).—A thesis presented for the degree of Ph. D. Essentially the same article has been noted elsewhere (E. S. R., 15, p. 452).

The rapidity of enzymic reactions, R. O. HERZOG (*Ztschr. Physiol. Chem.*, *41* (*1904*), *No. 5*, *pp. 416–424*).—The rapidity of enzymic reaction, according to the author, is dependent upon rate of diffusion. A formula for calculating it is given and discussed.

ZOOLOGY.

On the bearing of Mendelian principles of heredity on current theories of the origin of species, A. D. DARBISHIRE (*Reprinted from Mem. Manchester Lit. and Phil. Soc.*, *48* (*1904*), *pt. 3*, *No. 24*, *pp. 19–31*).—Notes are given on the difference between the continuous and discontinuous variation, and the theories of Galton and Mendel for explaining the inheritance of specific characters are briefly described. A bibliography of the subject is appended to the article.

Forest zoology, K. ECKSTEIN (*Allg. Forst u. Jagd Ztg.*, *1903*, *Sup.*, *pp. 71–83*).—Brief notes are given on work along the line of forest zoology in various parts of Germany for 1903. Attention was devoted to injurious mammals, birds, and insects.

Rabbits for profit, J. T. BIRD (*London: W. H. & L. Collingridge*, *1904*, *pp. 110*, *figs. 33*).—This volume is intended to contain the most recent and practical information regarding the various phases of rabbit raising with notes on breeds, foods, methods of feeding, rearing and housing, marketing of rabbits in a living and dead condition, and the common diseases of rabbits. The book is illustrated.

---

[a] Arb. K. Gesundheitsamte, Biol. Abt., 3 (1903), No. 5, pp. 445–545.

Wyoming ground squirrels (*Ranchman's Reminder, 1 (1904), No. 6, pp. 74–77, figs. 2*).—Brief notes on the appearance and distribution of ground squirrels in Wyoming with an account of injuries to various cultivated crops. For destroying these pests fumigation with carbon bisulphid is recommended.

The land and sea mammals of middle America and the West Indies, D. G. ELLIOT (*Field Columbian Mus., Zool. Ser., 4 (1904), pt. 1–2, pp. LXXXIII+850, pls. 58, figs. 309*).—The purpose of this report is to present an account of all the mammals of the North American continent and adjacent islands and seas from the northern boundary of Mexico to the Province of Cauca, South America. Analytical keys are presented for the determination of the species and a detailed description is given of each species of mammals.

Regulations for the protection of game in Alaska for the year 1904, J. WILSON (*U. S. Dept. Agr., Division of Biological Survey Circ. 42, pp. 6*).—A copy is given of an act for the protection of game in Alaska. This act was passed for the purpose of stopping the exportation of deer hides from Alaska and the killing and shipment of big game as trophies. The act is fulfilling its purpose in this regard. On the basis of this act, the Secretary of Agriculture is empowered to promulgate regulations from time to time regarding the seasons, permits, shipments, and transportation of game in Alaska. The regulations for 1904 are included in the circular.

Regulations for the protection of game in Alaska, J. WILSON (*U. S. Dept. Agr., Division of Biological Survey Circ. 39, pp. 6*).—This circular contains a copy of an act for the protection of game in Alaska together with regulations adopted by this Department for the execution of the game law.

Directory of State officials and organizations concerned with the protection of birds and game, 1903, T. S. PALMER (*U. S. Dept. Agr., Division of Biological Survey Circ. 40, rev. ed., pp. 12*).—Lists are presented of State officials, National organizations, State organizations, and Audubon societies concerned with the protection of birds and game in the United States and Canada.

Directory of State officials and organizations concerned with the protection of birds and game, 1904, T. S. PALMER (*U. S. Dept. Agr., Division of Biological Survey Circ. 44, pp. 15*).—As in previous circulars on this subject the addresses are given under four heads—State officials, National organizations, State organizations, and Audubon societies. Brief notes are also given on the methods adopted in the different States for the protection of game.

Definitions of open and close seasons for game, H. OLDYS (*U. S. Dept. Agr., Division of Biological Survey Circ. 43, pp. 8*).—Considerable lack of uniformity prevails in the statement of open and close seasons for game in the various States. It has been found doubtful in certain laws whether it is intended to include or exclude the dates mentioned at the beginning and expiration of open season. Greater uniformity in this matter is urged, together with a definite statement of the use of such prepositions as to, between, from, until, etc., in this connection.

Destruction of vermin (*Agr. Jour. Cape Good Hope, 25 (1904), No. 1, pp. 46, 47*).—Great losses to small stock and ostrich farming are reported from attacks of jackals and various methods are suggested for the destruction of these animals. It is recommended that jackal-proof fences be adopted as extensively as possible and that the poisoning method recommended by the Government be further applied.

Batrachians and reptiles of Ohio, M. MORSE (*Ohio State Univ. Bul., 8. ser., No. 18, pp. 91–144, pl. 1*).—A detailed list is presented of all the batrachians and reptiles known to occur in the State of Ohio together with artificial keys for the determination of the species, bibliographical references, directions for collecting and preserving these animals and a glossary of scientific terms.

A physiological theory to explain the winter whitening of birds and mammals in snowy countries, and the most striking points in the distribution of white in vertebrates generally, G. E. H. BARRETT-HAMILTON (*Rpt. British Assoc.*

Adv. Sci. 1903, pp. 698, 699).—In the author's opinion the belief that the winter whitening of animals takes place under the action of natural selection for protective purposes is not well founded. It is argued that this change possesses a deep physiological significance. The author noted a distinct sequence in which different parts of the body become white. On the whole this sequence corresponds to the parts in which the summer accumulation of fat takes place.

Attention is called to the fact that the belly of many animals where peripheral fat is thickest is permanently white and that the rump which usually shows the next thickest accumulation of fat is the first to become white in winter. The whitening of the feathers and hair is explained as a loss of pigment due to fat deposition and consequent atrophy. Many instances of white patches of hair, such as white face on the horse and white facial stripes on the badger are explained on the basis that they are located immediately over bone and thin membranes in which the circulation is not very vigorous and where atrophy and loss of pigmentation are likely to occur.

A handbook of the genera and species of birds, IV, R. B. Sharpe (*London: British Mus. Nat. Hist., 1903, pp. 391*).—In this volume the list of passerine birds is continued down to the end of the family Certhiidæ. It is stated that the work will be completed in one more volume.

Destruction of birds of prey, J. Aguet (*Jour. Agr. Prat., n. ser., 8 (1904), No. 35, p. 283*).—Attention is called to the wanton destruction of birds of prey and notes are given on the feeding habits of these birds, particularly their agency in the destruction of injurious rodents.

The protection of birds useful to agriculture, A. Meraz (*Com. Parasit. Agr. [Mexico], Circ. 8, pp. 21, figs. 8*).—Notes are given on the economic relations of a number of species of birds belonging to the various families.

Useful birds on the farm, how to attract and protect them, E. H. Forbush (*Ann. Rpt. New Jersey State Bd. Agr., 31 (1903), pp. 187–212, pls. 2, figs. 6*).—A brief account is presented of the economic importance of the birds with especial reference to their agency in destroying the injurious insects of wood lots, orchards, fields, and gardens. The majority of common birds are considered as being more beneficial than injurious, and suggestions are therefore made regarding methods of attracting these birds to orchards and gardens and protecting them in such situations.

The useful and injurious birds of New Jersey, S. N. Rhoads (*Ann. Rpt. New Jersey State Bd. Agr., 31 (1903), pp. 212–225*).—In the author's opinion the terms useful and injurious as applied to birds have not been defined with sufficient clearness and are therefore used quite loosely. As a rule, birds are believed to do more good than harm with the exception of the English sparrow, and more interest in their preservation is urgently recommended.

The birds of St. Vincent (*West Indian Bul., 5 (1904), No. 1, pp. 75–95*).—A brief account is presented of the geological conditions of St. Vincent with reference to the distribution of birds. The game birds of the islands are enumerated and described, and a list of birds including 84 species is presented. A copy is also given of an ordinance for the protection of birds.

[Bird migration], C. H. Merriam (*U. S. Dept. Agr., Division of Biological Survey Circ. 41, p. 1*).—Correspondents of the Department are requested to furnish notes regarding the dates of appearance and other facts noted concerning nighthawks, catbirds, kingbirds, red-eyed vireo, and redstart.

Bird migration in Great Britain and Ireland, A. Newton et al. (*Rpt. British Assoc. Adv. Sci., 1903, pp. 289–304*).—This constitutes the sixth and final report of the committee on bird migration. Particular attention is given in a statement furnished by W. E. Clarke to the migrations of the starling and rook.

Introduction of bats, L. G. Blackman (*Hawaiian Forester and Agr., 1 (1904), No. 5, pp. 115–117*).—Attention is called to the feeding habits of insectivorous bats and the possible benefits which might be derived from the importation of such bats.

It is suggested that the proper authorities make a study of this problem for the purpose of learning whether such introduction would be desirable.

Owls in their relation to agriculture (*Jour. Jamaica Agr. Soc., 8 (1904), No. 8, pp. 324–326*).—Brief notes are given on the habits of owls with especial reference to their economic importance. As a rule these birds are believed to render considerable assistance to agriculture in the destruction of injurious animals.

METEOROLOGY—CLIMATOLOGY.

Relation of weather to crops, A. J. McClatchie (*Arizona Sta. Bul. 48, pp. 345–456, pl. 1, fig. 1*).—This bulletin summarizes and discusses observations at the experiment farm near Phoenix during the past six years. The principal facts recorded are in brief as follows:

"The climate of an arid inland region is characterized by greater extremes of heat and cold than that of a humid coast region in the latitude, the winters being cooler and the summers warmer, and the difference between the temperatures of day and night greater. The climate at the station farm is a typical inland climate, and very trying on a large number of crops grown in the same latitude in a moist climate. If planted at the proper time, nearly all the crops grown in the temperate regions may be grown here more or less successfully.

"The small grains do well during winter, Indian corn fairly well during spring and fall, and Egyptian corn does well during summer. Few legumes are profitably grown here, peas doing fairly well during winter and cowpeas fairly well during summer. Cotton and sugar beets grow fairly well, but require a great deal of water at a time of the year when it is ordinarily scarce.

"The forage crops grown most successfully are alfalfa, small grains, and sorghum, the three furnishing green feed throughout the year. The most useful green manuring crop is what is known here as 'sour clover,' and to botanists as *Melilotus indica*. Most garden vegetables can be grown here quite successfully during winter and spring, those for which the climate is especially unsuited being winter squashes, beans, and rhubarb.

"No small fruits are generally grown with success, though strawberries were formerly grown in abundance and are still grown to a limited extent. Of deciduous fruits, grapes, peaches, apricots, plums and pears are successfully grown, while cherries and apples are grown with difficulty. The only nut-producing tree that thrives here is the almond. Citrus fruits do fairly well, but have not proven to be a reliable crop for profit. Olives and dates seem especially well adapted to the climate, and promise to be profitable crops. The cottonwood is the most easily grown timber tree, though the ash and a few species of Eucalypts grow quite well.

"Records from instruments located at different elevations from the ground show the importance of taking the situation of instruments into consideration in judging of the effect of recorded temperatures upon crops. Minimum temperatures average four or five degrees lower in government shelter 5 ft. from the ground than in the same shelter 50 ft. from the ground, and about three degrees lower at the ground than at the former point. Maximum temperatures average about three degrees higher 5 ft. from the ground than at 50 ft. from the ground, and ten to twelve degrees higher a few inches above the ground than at former location.

"The annual and the diurnal range of temperature is greatest at the surface of the ground, and decreases from there upwards and downwards. The lowest recorded temperature at 5 ft. underground has been 53; at 10 ft. underground 56, and at 15 ft. 58. The highest temperatures at these points have been 88, 76, and 73. Evaporation from a water surface ranges from a little over an inch per month during the coolest, dampest part of the year to over 10 inches during the warmest and driest part.

"Weather changes that are not periodic are due to inequalities in the density of the atmosphere. The indications of rain are: East or southeast wind, decreased diurnal range of temperature, slower evaporation, sinking of smoke or vapor. The indications of frost or cool weather are: West wind, increased diurnal range of temperature, rapid evaporation, clear sky. Grains hardy to frost are grown from October to June, and grains sensitive to frost from March to November. Melons grow from March to November, potatoes from February to June, and from August to December; tomatoes from March to December; corn from March to June and from July to November. Alfalfa grows some all the year, but makes the most growth from February to July and from September to November. Deciduous fruit trees grow from February to July, and evergreen fruit trees from March to July, and from September to December. Owing to the warm, dry climate insect pests and fungus diseases of plants are rare in the region."

A world-wide barometric seesaw, W. J. S. LOCKYER (*Nature [London], 70 (1904), No. 1808, pp. 177, 178, figs. 2*).—In this article an attempt is made to define the boundaries of two nearly antipodal parts of the earth in which barometric pressure varies in an inverse way. "So far as can at present be determined, one line commencing to the west of Alaska, separating this region from Siberia, passes easterly along about the 60th parallel of latitude, and runs in a southeasterly direction between southwest Greenland and northeast Canada. It then crosses the North Atlantic, passing to the north of the Azores, and skirts the southwestern portion of Portugal. It then strikes down towards the equator, cutting northwest Africa, so far as can be judged from the scant pressure values available, through the middle of the Sahara. It leaves Africa near the Gold Coast, and passes into the South Atlantic, where it can not be traced further owing to lack of observations in this southern ocean.

"The other boundary or neutral line passes to the northeast of Greenland and north of Iceland, crosses the southern portion of Norway and Sweden, and traverses southern European Russia. It then takes a course somewhat more easterly, skirting the northern part of the Caspian Sea and Turkestan, passes between Tibet and Mongolia, and through China. It then leaves the continent a little to the south of the Yellow Sea, and passes into the North Pacific Ocean. Here its path can not be traced, but it evidently passes well to the east of the Philippine Islands and Solomon Islands, takes a new southwesterly course, skirting the eastern side of Australia and passing between Tasmania and New Zealand. Its track is then again lost in the southern Pacific Ocean.

"Although too much weight must not at present be given to the positions of these neutral lines throughout their whole length, it is interesting to note that they are fairly symmetrical to one another, although no attempt has been made to make them so. Both lines apparently cross the equator at about antipodal points, and both appear to have a similar trend in northern and southern latitudes.

"The result of this survey seems to indicate clearly that there exists a general law relating to the pressure changes which occur simultaneously in these two extensive regions of the globe separated and defined more or less by a neutral line, this latter forming a fulcrum about which seesaws of pressure from one region to another take place.

Monthly Weather Review (*Mo. Weather Rev., 32 (1904), Nos. 4, pp. 159–206, figs. 4, charts 20; 5, pp. 207–254, figs. 5, charts 15; 6, pp. 255–301, figs. 6, charts 13*).—In addition to the usual reports on forecasts, warnings, weather and crop conditions, meteorological tables and charts for the months of April, May, and June, 1904, recent papers bearing on meteorology, etc., these numbers contain the following articles and notes:

No. 4.—Special contributions on Application of Salts of Radium to the Study of Atmospheric Electricity (illus.), by T. Moureaux; Studies on the Circulation of the Atmospheres of the Sun and of the Earth—V.—Results of the Nephoscope Observations in the West Indies during the years 1899–1903 (illus.), by F. H. Bigelow; The

Measurement and Utilization of Fog, by P. Leonard; The Formation of Snow in Cloudless Air near the Ground, by J. N. Weed; The Energy of a Unit of Light, by E. Buckingham; Meteor of September 15, 1902, by E. L. Moseley; Barometric Pressure at Orono, Me., by J. S. Stevens; Origin of American Cold Waves, by R. F. Stupart; Increased flow of Spring Water in the Autumn, by G. A. Loveland; The Temperature of the Air above Berlin (illus.), by R. Assmann; and notes on planetary meteorology; Weather Bureau men as instructors; meteorology in the universities; the observatory at Nice; and hypotheses as to the cause of the aurora borealis.

No. 5.—Special contributions on Studies on the Circulation of the Atmospheres of the Sun and of the Earth—VI.—The Circulation in Cyclones and Anticyclones, with Precepts for Forecasting by Auxiliary Charts on the 3,500-Foot and the 10,000-Foot Planes (illus.), by F. H. Bigelow; The Sensation of Discomfort, by W. F. Tyler; The Pressure of Sunlight and some of its Bearings on Astronomy and Meteorology, by S. A. Mitchell; The Promotion of Meteorology; Relation of Precipitation to Yield of Corn (illus.), by J. W. Smith (E. S. R., 16 p. 136); Invariability of our Winter Climate, by W. B. Stockman; The Crow Creek Flood of May 20, 1904, at Cheyenne, Wyo., by W. S. Palmer; and notes on the tornado in Indian Territory; tornado at Grand Rapids, Mich.; local cooperation in forest prevention; the triennial meeting, April, 1904, of the German Meteorological Society; the meteorology of the upper air; the meteorology of Jamaica; the curious work of the wind; instruction in meteorology; humming of telegraph wires and poles; note on the great meteor of September 15, 1902; and Weather Bureau men as instructors.

No. 6.—Special contributions on Frederic Henry Clarke; Earthquakes of June 25 and 26, 1904, by C. F. Marvin; Studies on the Circulation of the Atmospheres of the Sun and of the Earth—VII.—The Average Monthly Vectors of the General Circulation in the United States, by F. H. Bigelow; On the General Circulation of the Atmosphere in Middle and Higher Latitudes (illus.), by W. N. Shaw; Hourly Climatic Records on the Isthmus of Panama (illus.), by H. L. Abbot; Cyclonic Depression and Flood in Jamaica, by M. Hall; The First Electric Storm Recorded Automatically in St. Louis, Mo. (illus.), by J. Algué; and notes on temperatures in the upper atmosphere; auroras and thunderstorms; meteorology in Austria; Weather Bureau men as instructors; meteorology in the colleges and universities; and Silas West.

Weather reports, A. J. Mitchell (*Florida Dept. Agr. Mo. Bul. 14 (1904), Nos. 1, pp. 15–22; 2, pp. 17–24; 3, pp. 17–24; 4, pp. 17–24*).—Summaries of observations on temperature, precipitation, frosts, etc., at different points in Florida during January, February, March, and April, 1904.

Report on the weather of 1902 and 1903, J. W. Paterson (*West of Scotland Agr. Col. Bul. 19, pp. 15*).—This report gives a record of rainfall, temperature, and sunshine and general notes on the weather of each month at Kilmarnock and Glasgow during the years 1902 and 1903.

The [Philippine] Weather Bureau, D. C. Worcester (*Philippine Com. Rpt. 1903, pt. 2, pp. 55–58*).—A brief account of organization, equipment, and lines of work.

Report of the director of the Philippine Weather Bureau for the year ending August 31, 1903, J. Algué (*Philippine Com. Rpt. 1903, pt. 2, pp. 743–768, pls. 5*).—An account is given of the erection of new stations, inspection of stations, new instruments in the central observatory and branch stations, telegraphic service and work in branch stations, earthquake records, crop service, typhoon signals, publications, and astronomical and magnetic observations.

Meteorological observations, W. T. Ellis, R. Robertson, S. A. Bedford, A. Mackay, and T. A. Sharpe (*Canada Expt. Farms Rpt. 1903, pp. 47, 48, 263, 264, 298, 353, 396, 427*).—Summaries are given of observations on temperature, precipitation, etc., during 1903, at Central Experimental Farm, Ottawa; Nappan, Nova Scotia; Brandon, Manitoba; Indian Head, Northwest Territories; and Agassiz, British Columbia.

Meteorological observations in Sweden, 1902, H. E. Hamberg (*Meteor. Iakttag. Sverige [Observ. Météor. Suédoises], K. Svenska Vetensk. Akad., 44 (1902), pp. X+157*).—This is one of the series of reports of meteorological observations made under the direction of the Central Meteorological Institute and published by the Royal Academy of Sciences of Sweden.

It includes summaries of daily observations at 18 stations of the second order, monthly and annual summaries, general observations for 39 stations of the second order, the latter being also summarized in five-day periods. The results of observations on temperature alone are reported from 89 stations of the third order. The location, altitude, etc., of the stations are given, and some of the apparatus used and the methods of calculating results are described.

Observations on the mean distribution of rainfall in the Department of Gironde, G. Rayet (*Mém. Soc. Sci. Phys. et Nat. Bordeaux, 6. ser., 3 (1903), pp. 37–51, chart 1*).—Observations at different places (1892–1901) are summarized.

Rainfall in the Duff development concession during 1903, J. D. Gimlette and M. E. Scriven (*Agr. Bul. Straits and Federated Malay States, 3 (1904), I, No. 6, p. 235*).—The monthly rainfall and the greatest rainfall during 24 hours are given for the period of May to December, inclusive.

Rainfall measurements in Usambara, C. Uhlig (*Ber. Land. u. Forstw. Deutsch-Ostafrika, 1 (1903), No. 7, pp. 467–563, dgm. 1*).—The literature of meteorological observations in German East Africa is reviewed and all available measurements of rainfall are summarized and discussed.

Requirements of productive trees which can grow in arid countries without summer irrigation, P. Gennadius (*Cyprus Jour., 1 (1904), No. 1, pp. 6, 7*).—A summary is given of rainfall observations at 6 stations in the Island of Cyprus during the years 1881–2 to 1901–2. The average rainfall of the Island during the period was 17.45 in.

AIR—WATER—SOILS.

On the formaldehyde of the air, H. Henriet (*Compt. Rend. Acad. Sci. Paris, 139 (1904), No. 1, pp. 67, 68*).—Replying to Gautier's statement that air containing as much formaldehyde (2 to 6 gm. per 100 cubic meters of air) as the author reported in a previous paper would not be respirable, the author discusses the possibility of the presence of a polymer of formaldehyde in the air which yields the latter under the conditions of the method used in determining formaldehyde.

Observations at the Franco-Scandinavian station for exploration of the air at Hald (*Compt. Rend. Acad. Sci. Paris, 138 (1904), No. 26, pp. 1736–1737*).—A brief account of observations by means of kites and balloons.

A method of destroying or preventing the growth of algæ and certain pathogenic bacteria in water supplies, G. T. Moore and K. F. Kellerman (*U. S. Dept. Agr., Bureau of Plant Industry Bul. 64, pp. 44*).—This bulletin records the results of investigations begun in 1901, and which have included microscopic examinations of water with reference to nature and distribution of objectionable algæ and methods of removing them and studies of the effect of copper sulphate, colloidal copper, and other disinfectants on algæ and pathogenic bacteria. The nature and scope of the investigations and of the results reported are indicated in the following summary:

"The disagreeable odors and tastes so often present in drinking water are due almost exclusively to algæ, although the economic importance of studying these plants has not been recognized until recent years.

"These algal forms are widely distributed, and reservoirs in many States have been rendered unfit for use by their presence.

"The methods now known for preventing or removing the odors and tastes caused by algæ have proved unsatisfactory, either because of prohibitive expense or failure to accomplish result.

"It is therefore desirable that some new, cheap, harmless, and effective method be devised for ridding reservoirs of these pests.

"It has been found that copper sulphate in a dilution so great as to be colorless, tasteless, and harmless to man is sufficiently toxic to the algæ to destroy or prevent their appearance.

"The mode of application makes this method applicable to reservoirs of all kinds, pleasure ponds and lakes, fish ponds, oyster beds, water-cress beds, etc. It is also probable that the method can be used for the destruction of mosquito larvæ.

"At ordinary temperatures 1 part of copper sulphate to 100,000 parts of water destroys typhoid and cholera germs in from 3 to 4 hours. The ease with which the sulphate can then be eliminated from the water seems to offer a practical method of sterilizing large bodies of water, when this becomes necessary.

"The use of copper sulphate for the prevention of disease is regarded as incidental and is not designed in any way to supplant efficient preventive measures now in use. It is believed, however, that up to this time no such satisfactory means of thoroughly, rapidly, and cheaply sterilizing a reservoir has been known. Since the selective toxicity of copper sulphate renders it fatal to pathogenic forms peculiar to water, while the saprophytic or beneficial bacteria are unaffected, the method is particularly well adapted for this purpose.

"Definite knowledge in regard to what organisms are present, the constitution of the water, its temperature, and other important facts are necessary before it is possible to determine the proper amount of copper sulphate to be added. A microscopical examination thus becomes as important as a bacteriological or chemical analysis.

"No rule for determining the amount of copper sulphate to be added can be given. Each body of water must be treated in the light of its special conditions.

"The cost of material for exterminating algæ will not exceed 50 to 60 cts. per million gallons and will usually be less. The destruction of pathogenic bacteria requires an expenditure of from $5 to $8 per million gallons, not including the cost of labor."

Some refined methods in water purification, W. G. Toplis (*Amer. Jour. Pharm., 76 (1904), No. 3, pp. 116–121*).—A general discussion of some features of bacteriological examination of water, including a description of a filter of slag and sponge clippings in use at the lower Roxborough filter plant on the Schuylkill River.

Some water analyses, J. Sebelien (*Ber. Norges Landbr. Hoiskoles Virks., 1902–3, pp. 171–177*).—The paper reports and discusses the results of monthly examinations of water of different origin used for various purposes at the Agricultural College of Norway.—F. W. Woll.

Well waters from farm homesteads, F. T. Shutt (*Canada Expt. Farms Rpts. 1903, pp. 158–161*).—The results of analyses with reference to sanitary condition of 55 samples of water from miscellaneous sources are reported.

Cooperative fertilizer experiments on moor soils, 1903, H. von Feilitzen (*Svensk Mosskult. Tidskr., 18 (1904), No. 3, pp. 157–170*).—The report contains a brief account of the fertilizer experiments conducted under the direction of the Swedish Moor Culture Association during 1903. Fifty-five different trials were conducted in all, in 17 different counties, with small grains, legumes, roots, and tubers. The practical results of the trials are summarized at the end of the report, and brief general directions for the best methods of cultivation of moor soils are given.—F. W. Woll.

Soils, T. S. Dymond and F. Hughes (*Essex Education Com., Notes Agr. Anal. County Tech. Labs., 1904, pp. 7–15, 32, 33*).—Mechanical and chemical analyses of 24 samples of soil are reported and discussed with reference to their requirements for the production of different kinds of crops. The analysis of a sample of the soil from the celebrated potato-growing district near Dunbar, in Essex, shows the presence of high percentages of organic matter, nitrogen, available phosphoric acid, and lime, but only about the average amount of potash.

A study of the nitrogen content of a soil which has been continuously fertilized during 4 years shows that in 3 out of 4 cases nitrate of soda and superphosphate of lime have decreased the amount of nitrogen in the soil, basic slag has in every case increased and lime decreased it, and farm manure has in 2 cases increased and in 2 cases decreased it. Superphosphate and basic slag has in every case increased the proportion of clovers in the herbage. Lime has also increased the proportion, but to a less extent. Barnyard manure has decreased the proportion of clovers in 2 out of 3 cases and nitrate of soda in every case.

The exports of Jamaica in relation to the soil, H. H. COUSINS (*Bul. Dept. Agr. Jamaica, 2 (1904), No. 6, pp. 127–132*).—The results of analyses of 34 samples of material representing typical exports of the Island of Jamaica are reported and discussed with reference to "the actual drain on the mineral elements of the soil fertility of Jamaica by the annual removal of phosphoric acid and potash in the exports of the island." The average results show that 2,865,522 lbs. of potash and 896,712 lbs. of phosphoric acid are annually removed from the island in its exports.

Rhodesian soil analysis (*Rhodesian Agr. Jour., 1 (1904), No. 6, pp. 165, 166*).—The averages of 12 samples each of the typical red and granite soils of southern Rhodesia, which are remarkably uniform in chemical composition, are reported.

The conservation of moisture in orchard soils, F. T. SHUTT (*Canada Expt. Farms Rpts. 1903, pp. 129–132*).—This is a continuation during 1903 of previous years' investigations (E. S. R., 15, p. 126). The results of determinations May 14 and 23 and June 5 of moisture in different plats in the station orchard, which had been (1) under cultivation during the last 2 seasons, (2) in sod during the last 2 seasons, and (3) in sod in 1902, but plowed early in the season of 1903 (April 13), disked May 29, and cultivated June 3, are reported in comparison with data for precipitation during the same period. The results emphasize the value of cultivation as a means of conserving moisture.

The behavior of certain nitrogenous organic substances in the soil, A. MENOZZI (*Ric. Lab. Chim. Agr. R. Scuola Sup. Agr., Milan, 2 (1903), pp. 29–34*).—Studies of the absorptive power of a soil for sodium urate are briefly reported.

Investigation in soil bacteriology and its importance in determining the fertility of soils, P. EHRENBERG (*Landw. Jahrb., 33 (1904), No. 1, pp. 1–139; abs. in Chem. Ztg., 28 (1904), No. 45, Repert. No. 13, p. 159; Chem. Centbl., 1904, II, No. 25, p. 1615*).—On 5 soils, 2 of which were designated abnormal (very unproductive) and 3 of which by various treatments—manuring, etc.—were made productive, the author attempted to study the nitrogen utilization, loss, and combination, especially the extent to which these may be determined by bacteriological studies. In connection with vegetation experiments, some of which were made in the field, soils before and after the growth of crops were studied as to putrefaction capacity by Remy's method, for denitrifying power with Giltay's solution, nitrifying power (both nitrites and nitrates) according to Omeliansky, nitrogen-collecting capacity from the air by means of mannite solution according to Beijerinck.

Experiments were undertaken to improve the abnormal soils by inoculation, applications of manure, lime, and marl, as well as by modifying the climatic conditions. From the large mass of data obtained the following general conclusions are drawn: The phrase "bacteriologically abnormal soils" is not strictly accurate as applied to the soils studied in these investigations. Their unproductiveness was apparently due mainly to a deficiency of lime, which injuriously affected the growth of both the higher and the lower plants.

Inoculation with different kinds of soil bacteria, exclusive of the root tubercle bacteria, even in connection with applications of lime and manure did not bring about an appreciable effect. In the interpretation of vegetation experiments the plant species as well as its inherent capacity for assimilating plant food and requirements in this respect are of the highest importance, especially as regards lime. The

stirring of the soil in filling the pots and in making pot experiments does not appear to appreciably affect the bacteriological properties of the soil. The effect of manure can not be explained by its content of nitrogen and organic matter, especially when it is used on soils poor in lime.

While the results of the experiments reported show that the abnormal character of the soils was not of a bacteriological nature, they show in other respects the importance of bacteriological studies of soils—for example, the generally close relation between lime content and the activity of the soil bacteria. In an appendix the author gives a large number of suggestions and directions for the improvement of methods of bacteriological investigation of soils.

Studies on the bacterial flora of cultivated soils with especial reference to their behavior under fallow and when treated with carbon bisulphid, L. HILTNER and K. STÖRMER (*Arb. K. Gesundheitsamte, Biol. Abt., 3 (1903), No. 5, pp. 443–545, pls. 2, figs. 4*).—This is a comprehensive report dealing with methods of bacteriological examination of soils, the action of carbon bisulphid on the bacterial life of soils, and bacteriological studies of fallow soils. The methods of investigation which have been proposed by various investigators are critically reviewed and modifications suggested by the authors' work are described.

It is stated that the investigations show that carbon bisulphid exerts a selective action on the micro-organisms of the soil, retarding the action of some and promoting the activity of others. The action of the bisulphid was apparently beneficial in delaying nitrification at a time when the nitrates could not be completely utilized by the plants and were likely to be carried away in the drainage water. While the results of studies on fallow soils were not considered conclusive, they show in general that there was a decline in total number of organisms in the fallow plats, this being due exclusively to disappearance of organisms which do not liquefy gelatin.

Bacteriological and chemical studies of soils, WOHLTMANN, FISCHER, and SCHNEIDER (*Jour. Landw., 52 (1904), p. 97; abs. in Chem. Ztg., 28 (1904), No. 45, Repert. No. 13, pp. 159, 160*).—The beneficial effect of liming on bacterial activity is discussed.

The salt content of soils and its effect on the growth of cereals, V. PEGLION (*Staz. Sper. Agr. Ital., 36 (1903), No. 8–9, pp. 684–694; abs. in Centbl. Agr. Chem., 33 (1904), No. 8, pp. 507, 508*).—The results of examinations of 5 samples of soil with reference to salt and chlorin contents are reported. These show proportions of salt varying from 0.35 to 3.746 per cent, of chlorin from 0.028 to 1.17, the crop on the soil containing the smaller percentages being normal but entirely failing on the soil containing the larger percentages.

Basal examinations of Danish uncultivated moors, A. MENTZ (*Tidsskr. Landbr. Planteavl., 11, pp. 365–375*).—The paper gives a plan of basal examinations of Danish moor soils, according to which work has been in progress in western Jutland since 1901. The apparatus used in the examinations are described and the various phases of the investigation briefly discussed.—F. W. WOLL.

Geological-agronomic soil charts (*Mitt. Deut. Landw. Gesell., 19 (1904), No. 31, p. 204*).—A brief note referring to the geological charts of Prussia and neighboring states recently issued by the Royal Geological Bureau, calling attention especially to the information which they contain regarding chemical composition and other properties of the Prussian coast lands (sand dunes and forest soils).

On the existence of alkaline rocks in Central Africa, L. GENTIL (*Compt. Rend. Acad. Sci. Paris, 139 (1904), No. 6, pp. 413–415*).—The results of examinations of phonolites and rhyolites from the region of Tchad are briefly reported.

Reclamation of Cape Cod sand dunes, J. M. WESTGATE (*U. S. Dept. Agr., Bureau of Plant Industry Bul. 65, pp. 38, pls. 6*).—A report is given of the extensive expe. ents which have been conducted in attempts to fix the sand dunes which

surround Cape Cod Harbor, and to prevent the shifting of the sands, which would otherwise cause great damage by encroachment on valuable property. The botanical and physiographical features of the region are described and an account given of a natural reclamation as well as the artificial means which have been adopted for binding the Cape sands.

The artificial reclamation work has been carried on by private individuals, the State of Massachusetts, and the General Government for nearly a century. The most satisfactory results have been obtained where beach grass (*Ammophila arenaria*) was utilized, and since 1895 more than 200 acres have been planted to that species. The methods and cost of planting are described and the peculiar efficiency of this grass is pointed out.

In order to permanently reclaim the district forest species will be required, and a number of species of woody plants have already been tested with varying success. The most promising are the pitch, Austrian, and Scotch pines. The black locust and European or black alder are also proving of value, and the Scotch broom, although not entirely hardy, is said to be well adapted to certain situations.

Notes are given on the ownership of the lands and their value, and the report concludes with a brief bibliography of the literature relating to the subject.

FERTILIZERS.

Manures, T. S. Dymond and F. Hughes (*Essex Education Com., Notes Agr. Anal. County Tech. Labs., 1904, pp. 15–22, 34–39*).—Analyses of a large number of fertilizing materials are reported and discussed.

Report on experiments with green manures in Pomerania, D. Baessler (*Mitt. Deut. Landw. Gesell., 19 (1904), No. 32, pp. 205–207*).

Cooperative fertilizer experiments in Malmöhus County, Sweden, during 1903, G. Nordin and M. Weibull (*Malmö. Läns Kgl. Hush. Sällsk. Kvart., 1904, No. 1, pp. 143–201*).—The cooperative fertilizer experiments conducted under the auspices of the Malmöhus County Agricultural Society were continued during 1903, 80 different trials being made, viz, 26 with sugar beets, 5 with fodder beets and potatoes, 5 with pastures, and 44 with barley, oats, wheat, and rye. The experiments were conducted on 44 different farms, and were planned to ascertain the economy of different practical systems of fertilization. The report gives detailed information as to the different trials, including character and history of soils, fertilizers applied, data obtained at harvesting time, and the economy of the applications of fertilizers.

The highest returns were obtained from applications of nitrogenous fertilizers only in about one-third of the number of trials, one-third gave the highest returns from nitrogen and phosphoric acid, and nearly one-third from a complete fertilizer. In 96 per cent of the trials fertilization with nitrate was required (as in 1902), in 64 per cent a phosphoric-acid fertilization, and in 36 per cent potash fertilization were required (against 70 and 43 per cent, respectively, in 1902). Potatoes and root crops gave the highest returns for the expenditure of fertilizers, then winter grains, and least spring grains and hay.

Fertilizer experiments with peat litter.—Three trials were conducted with peat litter for the purpose of determining how it may best be supplemented with potash and phosphoric acid. The results obtained during the year in which the fertilizers were applied indicate that only soils in need of nitrogenous fertilizers are benefited by applications of peat litter (1,500 kg. per hectare). Soils that call for applications of phosphoric acid or potash, or both, besides nitrogen, require an addition of superphosphate or potash (or both) in order that the peat may give economical results. At present prices of fertilizers it is not believed that peat litter will prove an economical fertilizer except perhaps on farms located in the vicinity of peat factories.

Residuary effect of artificial fertilizers.—The residuary effect of applications of artificial fertilizers in 1902 on meadow grass was studied in one trial. While the fertilizers applied paid well the first year, the yields and net profits obtained in the case of the different plats in 1903 were still greater, and in the same direction for each plat as in 1902, the highest results being obtained on the plat receiving 1,000 kg. of Thomas phosphate and 100 kg. of 37 per cent potash salt per hectare.

On the effect of fertilizers on the quality of root crops.—The experiments conducted with root crops during two years indicate that the quality of both potatoes and fodder beets is much more easily influenced by artificial fertilizers than that of sugar beets. It is therefore important to develop varieties of other root crops containing a high percentage of dry substance which are not appreciably affected by the fertilizers applied, as has been done to a large extent in the case of sugar beets under the encouragement of sugar factories.

Soil analyses and their practical value.—A large number of samples of the soils used on the experiments were subjected to chemical, mechanical, and petrographical analyses, and the results thus obtained are discussed in detail by the author in view of recent investigations on the subject of soil analysis. The following average results were obtained for the various kinds of soils examined, the number of samples included in the analyses for 1902 being 34 and, for 1903, 43.

Summary results of analyses of Swedish cultivated soils.

	Silt.	Alumina.		Kaolin.	Total iron.	Humus.	Nitrogen.	Phosphoric acid.	Potash.
		Total.	Kaolin.						
	Per ct.	*Per ct.*	*Per ct.*	*Per ct.*	*Per ct.*	*Per ct.*	*Per ct.*	*Per ct.*	*Per ct.*
Stiff clay soils:									
1902	63.6	9.76	....	....	4.22	9.90	0.39	0.10	0.33
1903	64.3	7.49	3.83	9.6	6.72	9.14	.27	.09	.27
Medium clay soils:									
1902	50.1	6.13	....	....	4.57	7.16	.29	.09	.19
1903	50.0	5.80	3.55	8.8	5.27	5.80	.23	.07	.18
Light clay soils:									
1902	34.1	3.99	....	....	2.92	5.07	.20	.09	.15
1903	37.6	3.83	2.48	6.2	3.66	4.82	.10	.07	.14
Clayey sandy soils:									
1902	24.8	1.86	....	....	2.43	5.72	.26	.08	.12
1903	26.8	1.96	1.01	2.5	2.96	4.51	.17	.05	.11
Sandy soils:									
1902	14.2	.54	....	......	2.01	3.56	.15	.09	.10
1903	22.9	.81	.28	.7	2.52	5.56	.18	.09	.08

The practical value of soil analyses is discussed on the basis of the results obtained. The determinations of nitrogen and phosphoric acid are shown to be of no particular value for the class of soils examined, since practically all the soils responded to applications of these fertilizing materials. As to the potash requirements of these soils the author concludes that soils have different requirements according to their physical character.

The following average figures were found for the potash contents of the soils examined: Stiff clay 0.25 per cent, medium clay 0.20, light clay 0.15, and sandy soils 0.10 per cent. A deficiency of potash may be determined by comparing the percentage found with these figures. The crop to be grown and the weather conditions are, however, important factors in determining whether a soil will respond to an application of potash.

On the lime content of Skåne soils.—Most of the soils analyzed were examined for their content of lime as carbonate, assimilable lime (obtained by digestion with a 10 per cent ammonium-chlorid solution on a steam bath for 3 hours), and lime soluble in cold dilute hydrochloric acid. Without discussing the results obtained, which are not considered sufficiently numerous by the author to permit of definite, final conclusions being drawn, the following summary table is reproduced showing the average lime content in Skåne soils of different physical characteristics:

Lime content of Skåne soils.

	Number of analyses.	Lime.		Soluble in hydrochloric acid.
		Carbonate.	Assimilable.	
		Per cent.	*Per cent.*	*Per cent.*
Stiff clay	6	0.01	0.37	0.45
Medium clay	8	.01	.38	.64
Light clay low in lime	40	.06	.34	.51
Light clay high in lime	8	.66	.88	1.61
Sandy soils low in lime	21	.06	.27	.28
Sandy soils high in lime	10	1.15	.47	1.77

The stiff clays are considered sufficiently rich in lime for crop-growing purposes, but their mechanical condition will be improved by liming. The sandy and gravelly soils in the northern part of the county, which have been derived from moraines lying on top of the primitive rocks, Keuper, or carboniferous formations, need lime applications, while the light clays (moraine clay) in general contain sufficient lime for crop production.—F. W. WOLL.

Cooperative fertilizer experiments in Denmark, E. VON SYDOW (*Malmö. Läns Kgl. Hush. Sällsk. Kvart., 1904, No. 1, pp. 202–207*).—A general discussion of the plan and organization of the experiments.—F. W. WOLL.

Increasing the yield by high phosphoric-acid manuring, P. WAGNER (*Ztschr. Landw. Kammer Schlesien, 8 (1904), p. 64; abs. in Centbl. Agr. Chem., 33 (1904), No. 7, pp. 437–439*).—Plat experiments are reported which show that the effect of Thomas slag was felt on grass lands 9 years after its application. Other experiments with oats, rye, clover, beets, peas, etc., extending over 12 years showed that continuous medium applications of slag were continuously beneficial. The slag, however, should be used with caution. The poorer the soil in calcium carbonate, iron, and alumina the smaller the application of phosphoric acid required, and vice versa. The author states also that the richer soils are in phosphoric acid the smaller the applications of nitrogen required.

Report on experiments in pots in 1902 on the value of the accessory constituents of artificial manures, J. W. PATERSON (*West of Scotland Agr. Col. Bul. 20, pp. 19–31*).—Experiments on oats with ammonium sulphate, superphosphate, and kainit are reported. These were compared with pure salts—phosphates of ammonium and potash; sulphates of calcium, sodium, potassium, and magnesium; and chlorids of sodium, potassium, and magnesium. The following conclusions are drawn from the results:

"Nitrogen, phosphates, and potash are the important constituents of artificial manures. In supplying these a limited amount of sulphuric acid as sulphate is desirable in order to obtain a full return. Such sulphate tends to increase the grain as distinct from the straw of oats. The sulphate in a commercial mixture should not be overdone, however, to the exclusion of chlorids (muriates). In giving a complete manure, the choice in regard to the best form of potash should be decided by whether the nitrogenous and phosphatic manures contain sulphate. If they do not, muriate of potash should not be chosen. If they do, sulphate of potash should be neglected for some of the other forms of potash."

Complete humus fertilizers, J. DUMONT (*Compt. Rend. Acad. Sci. Paris, 138 (1904), No. 23, pp. 1429–1431*).—An account is given of experiments with a humus fertilizer prepared by treating a black humus soil containing 2 per cent of nitrogen with a concentrated potash solution in which aluminum phosphate had been dissolved. The dried product contained soluble matter (humates) 50.4 per cent, nitrogen 1.6 per cent (0.98 per cent soluble), phosphoric acid 2.9 per cent (1.34 per cent soluble), potash 5.5 per cent (all soluble).

The phosphoric acid was apparently combined with the humus in form of phosphohumate compounds, and was quite completely precipitated along with the humus by addition of citric and hydrochloric acids, ferric chlorid, aluminum sulphate, and calcium chlorid, especially the last which removed practically all phosphoric acid from solution.

The humus fertilizer was tested in amounts varying from 400 to 1,000 kg. per hectare (350 to 880 lbs. per acre) with good results on alfalfa, sugar beets, potatoes, and wheat. With alfalfa the results with the fertilizer were better than with chemical fertilizers. The sugar content of the beets was 3 per cent higher where the humus fertilizer was used than where no fertilizer was applied. Tests made on calcareous clay soil showed that the soluble nitrogen of the humus fertilizer nitrified as rapidly as that of blood.

Further experiments with ammonium sulphate and sodium nitrate, Bachmann (*Fühling's Landw. Ztg., 53 (1904), Nos. 13, pp. 502–506; 14, pp. 539–543*).—A number of field experiments with rye, oats, barley, etc., grown on sandy soils are reported to show that ammonium sulphate not only gave larger total yields, but also larger amounts of protein than sodium nitrate.

The use of fertilizers; a review of the results of experiments with nitrate of soda, E. B. Voorhees (*New Jersey Stas. Bul. 172, pp. 32*).—The general principles underlying the use of fertilizers and the conditions under which the use of nitrate of soda is to be especially commended are discussed, and the results of experiments with nitrate of soda on high value market-garden crops and on low value field crops, reported in previous bulletins (E. S. R., 14, p. 247; 15, pp. 242, 251), are reviewed, with practical suggestions as to methods of using nitrate of soda on different kinds of crops.

Investigations on the action of different forms of lime and magnesia, D. Meyer (*Fühling's Landw. Ztg., 53 (1904), No. 14, pp. 528–534*).—A general discussion.

Basic superphosphate, G. Appiani (*Ric. Lab. Chim. Agr. R. Scuola Sup. Agr., Milan, 2 (1903), pp. 131–133*).—Studies of the chemical composition and solubility in citric acid of basic superphosphates made from Tennessee and Gafsa phosphates by the Hughes process (E. S. R., 14, p. 343) are briefly reported.

Commercial fertilizers, J. L. Hills, C H. Jones, and F. M. Hollister (*Vermont Sta. Bul. 108, pp. 297–364*).—This bulletin reports the results of analyses of 118 brands of fertilizers, representing the output of 10 companies, with a discussion of the quantity and quality of plant food furnished in the different fertilizers, selling prices and valuations, classification of brands sold in the State, and comparison of the composition of fertilizers sold in Vermont during 5 years past. The effect of food, care of animals, stable construction and management, and use of absorbents, etc., on the character of farm manures; as well as the causes and prevention of manurial waste, are also discussed with suggestions as to use and application of manures.

Commercial fertilizers, G. Roberts (*California Sta. Bul. 157, pp. 30*).—This bulletin gives the text of the State fertilizer law, approved March 20, 1903; the rules and regulations adopted under its provisions; explanations of terms used in fertilizer analyses; and analyses and valuations of a large number of samples of fertilizers examined in accordance with the law.

Commercial fertilizers, J. H. Stewart and B. H. Hite (*West Virginia Sta. Bul. 92, pp. 64*).—This is a report on fertilizer inspection during the period from May 1 to December 31, 1903.

Analysis of commercial fertilizers sold in Maryland, H. B. McDonnell et al. (*Maryland Agr. Col. Quart., 1904, No. 23, pp. 48*).—The results of analyses of fertilizers inspected from August, 1903, to January, 1904, inclusive, are reported.

Analysis of commercial fertilizers sold in Maryland, H. B. McDonnell et

AL. (*Maryland Agr. Col. Quart., 1904, No. 25, pp. 54*).—The results of analyses of 460 samples of fertilizers examined from March to June, 1904, are reported, with notes on valuation.

Fertilizer analyses, fall season, 1903, to spring season, 1904, B. W. KILGORE (*Bul. North Carolina State Bd. Agr., 25 (1904), No. 6, pp. 1–65*).—The names and guaranteed composition of fertilizers registered for 1904, and analyses and valuations of 595 samples of commercial fertilizers, 84 samples of cotton-seed meal, examined during the fall of 1903 and spring of 1904, with explanations regarding terms used in fertilizer analyses, freight rates, valuation, etc.

Fertilizer analyses, B. W. KILGORE (*Bul. North Carolina State Bd. Agr., 24 (1903), No. 7, pp. 66*).—Analyses of fertilizers and of cotton-seed meal examined during the fall and spring seasons, 1902–03, with a list of brands of fertilizers registered for 1903.

Naturally occurring fertilizers and waste products, F. T. SHUTT (*Canada Expt. Farms Rpts. 1903, pp. 148–152*).—This article discusses the nature and treatment of swamp muck, the fertilizing value of tobacco and potato starch factory refuse.

FIELD CROPS.

Field experiments with farm crops, W. SAUNDERS, J. H. GRISDALE, W. T. MACOUN, F. T. SHUTT, J. FLETCHER, C. E. SAUNDERS, R. ROBERTSON, S. A. BEDFORD, A. MACKAY, and T. A. SHARPE (*Canada Expt. Farms Rpts. 1903, pp. 5–46, 49–55, 79–87, 111–114, 132–134, 144–148, 212–215, 217–238, 264–284, 310–333, 355–375, 397–412*).—The work with field crops at the Canada Experimental Farms in 1903, which is in continuation of previous experiments (E. S. R., 15, p. 135), is reported. The results of variety tests with most of the crops mentioned have been noted from a previous publication (E. S. R., 15, p. 861).

Wheat.—The work with wheat at Ottawa, including breeding new varieties, milling tests, chemical analyses, and fertilizer experiments is reviewed. The breeding of new varieties has been noted from another source (E. S. R., 15, p. 352). Milling tests were made of samples of the crossbred varieties Preston, Stanley, and Percy, from Ottawa and Indian Head, and compared with samples of Red Fife from the same sources. All are considered good milling wheats, but the 2 samples of Red Fife and the sample of Stanley from Ottawa are regarded as best. According to the report of an English expert, samples of Percy and Stanley from Indian Head were equal to Red Fife as regards color, strength, appearance, and milling structure. The analyses of the same class of samples are given in the following table:

Analyses of wheats.

Variety.	Locality where grown.	Weight per bushel.	Weight of 100 kernels.	Moisture.	Albuminoids.	Fat.	Crude fiber.	Ash.	Carbohydrates.	Gluten.	
										Wet.	Dry.
		Lbs.	*Grams.*	*Per ct.*	*Per ct.*	*Per ct.*	*Per ct.*	*Per ct.*	*Per ct.*	*Per ct.*	*Per ct.*
Percy	Indian Head	62	2.828	11.50	12.50	2.26	1.79	1.47	70.48	38.10	14.78
Preston	do	63½	3.022	11.48	11.63	2.25	1.85	1.68	71.11	31.68	12.34
Red Fife	do	62½	3.164	11.44	12.44	2.48	1.86	1.36	70.42	34.68	13.43
Stanley	do	62¼	3.019	11.08	12.41	2.42	1.88	1.44	70.77	37.48	14.18
Percy	Ottawa	62	3.551	12.05	13.56	2.14	2.09	1.91	68.25	41.59	16.64
Preston	do	63	3.680	12.22	12.22	2.46	1.83	1.88	69.39	35.93	14.26
Red Fife	do	61	3.302	12.79	12.41	2.43	2.02	1.84	68.51	34.35	13.55
Stanley	do	62	3.551	12.23	12.34	2.44	2.08	1.71	69.20	33.95	14.22

Further milling tests and analyses reported show that samples of White Fife and Early Riga from Ottawa were of excellent quality, and that samples of Goose from Ottawa and Indian Head were very poor for milling and bread making. The parentage and characters of Preston, Stanley, Huron, Percy, and Laurel are noted.

The records for several years show that Harold, Gehun, Early Riga, Fraser, and Ebert, the earliest varieties now grown at Ottawa, are about 2 weeks earlier than Red

Fife, and about 1 week earlier than Preston. Of a dozen varieties of macaroni wheat Yellow Gharnovka, Gharnovka, and Beloturka, yielding 33 bu. 40 lbs., 31 bu. 20 lbs., and 31 bu. 20 lbs., respectively, proved most productive. Sixteen varieties of winter wheat sown September 6 and harvested from July 18 to 25, varied in yield from 29.25 to 45.25 bu. per acre. The leading varieties were Turkey Red and Dawson Golden Chaff, all others producing less than 40 bu. per acre.

At Brandon, seed from large heads of 26 varieties yielded on an average 30 bu. 10 lbs. per acre, against 29 bu. 50 lbs., from unselected seed. Seven varieties grown on summer fallow on plats from 2 to 5 acres in size, yielded from 26 bu. 50 lbs. to 41 bu. 20 lbs. per acre, with White Connell as the leading variety. A comparison of a shoe and a disk drill for sowing wheat showed no material difference in yield. Four different methods of bluestone and formalin treatment to prevent wheat smut proved effective.

In addition to the regular plat experiments 9 varieties of spring wheat were grown in field lots at Indian Head, and of these Huron gave the largest yield, 40 bu. 24 lbs. per acre. The average yield per acre for all varieties was 35 bu. 48 lbs. Notes on summer fallowing and breaking up and cultivating new prairie lands are given.

At Agassiz, Oregon Club and Blue Stem, sown September 22 and April 25, yielded, respectively, 49 bu. 20 lbs. and 46 bu. 40 lbs. per acre for the fall sowing, and 37 bu. 20 lbs. and 38 bu. 40 lbs. for the spring sowing.

Spelt, emmer, and einkorn.—Descriptions of these crops are given and the yields and characters of the different varieties recorded. At Ottawa the yields of 11 varieties of spelt and emmer ranged from 1,020 to 2,660 lbs. per acre, and in a single test einkorn yielded 2,720 lbs. per acre. Red spelt and Smooth spelt were the leading varieties among the spelts, and Long emmer, with a yield of 1,760 lbs. per acre, was the leading emmer.

At Nappan, White spelt, White Bearded spelt, Common emmer, and White emmer yielded 29⅓, 28⅗, 25⅓, and 23⅓ bu. per acre, respectively. The 2 spelts weighed, respectively, 35 and 34 lbs. per measured bushel. White emmer at Brandon yielded 43 bu. 50 lbs., Red emmer 38 bu. 40 lbs., Smooth spelt 29 bu. 20 lbs., and White Bearded spelt 27 bu. per acre. The emmers weighed 47½ and 39 lbs. per measured bushel, respectively, while the spelts weighed only 26 lbs.

Red Fife wheat, Banner oats, and Mensury barley were grown after spelt or emmer, summer fallow, and wheat, and in each case the highest yields were obtained where the crops followed spelt or emmer, and the lowest where they followed wheat. At Indian Head Common emmer and Red emmer yielded 54⅗ and 42½ bu., and White spelt and Black Bearded spelt 39⅗ and 26⅓ bu., respectively. The yield per acre of 6 varieties of spelt and emmer at Agassiz was as follows: Common emmer 2,190, South Dakota No. 3 2,130, South Dakota No. 524 2,040, Red Spelt 1,960, Thick emmer 1,920, and White Bearded spelt 1,720 lbs. The yields of straw per acre from these varieties ranged from 4,600 to 4,120 lbs. The period of growth of these crops at the different farms varied from 114 to 143 days.

Oats.—The culture tests with oats are reviewed and the results with some of the best varieties noted. The following analysis of Banner oats grown at Ottawa in 1902, is reported:

Composition of the whole grain, kernels, and hulls of Banner oats.

	Proportion to whole grain.	Moisture.	Albuminoids.	Fat.	Carbohydrates.	Fiber.	Ash.
	Per ct.	*Per ct.*	*Per ct.*	*Per ct.*	*Per ct.*	*Per ct.*	*Per ct.*
Oats (whole grain)	....	12.74	11.22	4.82	58.84	9.47	2.91
Kernels	71.92	12.03	14.51	6.21	63.15	1.93	2.14
Hulls	28.08	10.19	2.60	.78	49.63	31.63	5.17

The experience at Ottawa has been that the earliest varieties, and notably Wallace, Welcome, and White Wonder, are low in yield. At Brandon Abundance, Waverly, Banner, Tartar King, and Improved Ligowo drilled on summer-fallowed plats of clay loam soil, from 3 to 7 acres in size, yielded 86 bu. 18 lbs., 86 bu. 5 lbs., 83 bu. 15 lbs., 82 bu. 30 lbs., and 73 bu. 18 lbs., respectively.

Banner oats after flax, millet, summer fallow, and turnips produced, respectively, 117 bu. 12 lbs., 115 bu., 102 bu. 32 lbs., and 85 bu. 10 lbs. per acre. On field plats at Indian Head, Banner and Abundance among 9 varieties led in productiveness, with 119 bu. 2 lbs. and 106 bu. per acre; required 122 and 124 days to mature, and weighed 38 and 39 lbs. per measured bushel, respectively. The average yield per acre of the 9 varieties was 95 bu. 8 lbs.

Barley.—The earliest varieties of 6-rowed barley grown at Ottawa for 5 years or more, are Odessa, Stella, and Trooper, being about 1 day earlier than Blue Long Head and Mensury. Of the 2-rowed varieties Jarvis, Beaver, and Gordon, all crossbred sorts produced at Ottawa, were the earliest. Canadian Thorpe and French Chevalier ripened 2 or 3 days later. At Brandon, Mensury 6-rowed produced the best yield when grown after millet, as compared with following summer fallow, flax, and turnips, mentioned in the decreasing order of yield. An average yield of 56 bu. 25 lbs. per acre was obtained from four 2-rowed and five 6-rowed varieties grown on field plats of fallow and brome grass sod.

Rye.—Spring rye sown April 17 required 115 days to mature at Ottawa, and yielded in bushels of 56 lbs. 21 bu. 24 lbs. per acre. A yield of 38. bu. of grain and 4,540 lbs. of straw per acre was obtained at Indian Head. Fall rye at Indian Head sown October 7 ripened August 20 and yielded 46 bu. 20 lbs. per acre.

Corn.—Champion White Pearl, Selected Leaming, and Longfellow were grown at Ottawa, as in previous years, in rows 21, 28, 35, and 42 in. apart, and in each case the yield favored the closest planting. The results have varied in different years, but this is believed to be due to the character of the season. At Nappan the results of an experiment on the same plan were generally in favor of the wider rows.

At Brandon, the yield in every instance was again highest with the closest planting. The average yield of green corn at Brandon from rows 30 and 36 in. apart was about the same, while the rows 42 in. apart produced over 5 tons less per acre. Early Amber Rice and White Pearl pop corn failed to mature grain at this farm, but yielded 14.80 and 18 tons of green fodder per acre, respectively. The distance tests at Indian Head resulted in favor of the 21-in. rows with Longfellow and Champion White Pearl, and in favor of the 28-in. rows with Selected Leaming. At Agassiz, where the varieties were grown in hills and drills at the different distances, the results indicated that drilling in rows 3 ft. apart was likely to be most generally satisfactory.

Peas.—The earliest varieties at Ottawa were Chancellor and White Wonder, which ripened about 2 days before Paragon and Arthur, 2 crossbred varieties produced at the experimental farms. Chancellor, with a period of growth of 118 days, yielded 30 bu. 20 lbs. per acre, while White Wonder produced only 22 bu. 40 lbs.

Potatoes.—Of 15 varieties tested at Ottawa in 1903, in addition to the regular tests on uniform plats, 9 gave yields of over 300 bu. per acre. Morgan Seedling and Vermont Gold Coin, the 2 leaders in this test, produced at the rate of a little over 522 and 477 bu. per acre, respectively. At Brandon, in similar experiments, Peachblow and Chenango ranked first, with 539 and 446.6 bu. per acre, respectively. Digging 17 early varieties on August 8 and 20, and September 4, at Nappan, showed that the average yield of marketable tubers increased from 157 bu. 56 lbs., the yield obtained August 8, to 241 bu. 56 lbs. by August 20. After this date there was no further gain in yield.

Tests at this farm with tubers cut in different ways for planting were in favor of sets made by cutting the tuber in two, lengthwise. Medium-sized whole tubers gave nearly as good results. A plat planted with sets treated with air-slaked lime

gave a somewhat better yield than the check plat. In a fertilizer test at Agassiz, 100, 150, and 200 lbs. of Thomas slag increased the yield, respectively, over the untreated plat by 88.6, 92.7, and 102.4 bu. per acre.

Flax.—At Ottawa, Riga flax yielded at the rate of 22 bu. and White Russian at the rate of 24 bu. per acre. Seven varieties compared at Brandon were sown June 2 and harvested from August 25 to September 1. Navarossick, the leading variety, yielded 26 bu. 44 lbs. of seed per acre; followed by La Plata, with 20 bu. 40 lbs. Bombay yielded only 8 bu. 32 lbs. per acre. Sowing 60 lbs. of seed per acre gave a better yield than either thicker or thinner sowing. Improved Russian and Early Riga, sown at Agassiz May 7, ripened August 10, and yielded, respectively, 14 bu. 23 lbs. and 12 bu. 8 lbs. of seed per acre.

Buckwheat.—A test of 5 varieties made at Nappan resulted in favor of Silver Hull, yielding 45 bu. 40 lbs. per acre, with Rye buckwheat, yielding an even 45 bu., ranking second. On 4½ acres of new land Silver Hull produced 23 bu. 16 lbs. per acre.

Root crops.—Analyses of mangels, carrots, and turnips show that Giant Sugar Feeding, Half Long Sugar White, and Half Long Sugar Rosy, varieties known as sugar mangels, led in sugar content with, respectively, 10.40, 9.82, and 9.61 per cent of sugar in the juice. Gate Post and Giant Yellow Globe mangels have been compared for 4 years, but the changes due to season did not disturb the relative position of the 2 varieties with reference to the percentage of dry matter and sugar, Gate Post being the leader. Results with sugar beets at the different experimental farms and other points are also briefly noted.

The results of experiments at Ottawa in sowing root crops on May 7 and 21 and harvesting on October 19 and November 2 show that turnips and sugar beets produced the largest yields from the early sowing and early harvesting, and mangels and carrots from the early sowing and late harvesting. Owing to the season the results with root crops did not harmonize with those of previous years. At Nappan 5 varieties of turnips were sown on acre plats and fertilized at the rate of 250 and 500 lbs. of complete commercial fertilizer after a general dressing of barnyard manure had been given. In each case the heavier application gave the largest yield, but the difference in its favor was not very large. An experiment with mangels on the same plan gave similar results.

Grasses and other forage crops.—Soy beans and horse beans at Ottawa gave better yields in 28-in. rows than in 21-in. rows. At Nappan and Indian Head better yields were obtained from 21-in. rows than from 28 or 35 in. rows, while at Agassiz the results were in favor of the rows 28 in. apart. The leading varieties of millet at Ottawa were Pearl and Algerian, yielding 8.08 and 6.4 tons of green fodder and 3.92 and 4.6 tons of hay per acre, respectively. At Brandon the best yields were in favor of Algerian and Moha Hungarian millets, while at Indian Head Hungarian and White Round French stood first, with a yield of 6 tons each. At Agassiz White Round Extra French and Red Orenburg were the leading varieties, yielding 3 tons and 1,920 lbs. and 3 tons 960 lbs. per acre, respectively. Canary grass (*Phalaris canariensis*) required 131 days to mature at Indian Head and produced 29 bu. 20 lbs. of seed and 3,960 lbs. of straw per acre. The yields of brome grass (*Bromus inermis*), Western rye grass (*Agropyrum tenerum*), alfalfa, and timothy at this farm are also recorded.

In 1900 a series of plats were sown with grain and the alternate plats were sown at the same time with clover at the rate of 12 lbs. per acre. This crop of clover was plowed under and the increase in yield of wheat, oats, barley, corn, potatoes, mangels, turnips, sugar beets, and carrots for the next 3 years was observed. In every case the use of clover showed an increase in yield.

At Ottawa, among 5 different grass mixtures grown for hay, 10 lbs. of timothy and 8 lbs. of common red clover per acre gave the best results. In a similar experiment at the same place a mixture consisting of 5 lbs. of timothy, 4 lbs. of Awnless brome

grass, 2 lbs. of orchard grass, 6 lbs. of alfalfa, and 3 lbs. of alsike clover gave a total annual yield of 4.38 tons per acre, being the highest yield for all mixtures. In 1902 this mixture stood second. For the dry districts of the West a mixture of 12 to 15 lbs. of alfalfa and 6 lbs. of brome grass is recommended.

Good yields have also been obtained throughout the country from ½ bu. each of tares and oats, peas and oats in the same proportion, and 1 bu. each of peas, wheat, and oats; or of peas, wheat, and late barley. Notes on the culture of sainfoin are given in this connection. At Brandon Mammoth Red clover yielded 2.35 tons of hay per acre, as compared with 1.8 tons for common red clover and 0.9 of a ton for alsike clover. Two cuttings of alfalfa in this series of tests yielded a total of 3.75 tons of hay per acre.

Miscellaneous.—The conclusions drawn from fertilizer experiments with wheat, barley, and oats, in progress since 1888, have been previously reported (E. S. R., 14, p. 130). A series of experiments with different fertilizers in different combinations, including superphosphate of lime and Thomas slag, has heretofore been described (E. S. R., 15, p. 135). This season the best yield, 20 bu. of wheat per acre, was obtained from the plats receiving 800 lbs. of Thomas slag alone, 400 lbs. of Thomas slag with 200 lbs. of kainit, and 400 lbs. of Thomas slag, 200 lbs. of kainit, and 100 lbs. of nitrate of soda per acre.

The yield of oats was in favor of an application of 1,000 lbs. of fresh slaked lime per acre, being followed by applications of 100 and 200 lbs. of nitrate of soda. The highest yields of brome-grass hay were obtained on the plats receiving 400 lbs. of superphosphate of lime and of Thomas slag, each applied alone. The yields amounted to 3.8 and 2.8 tons per acre, respectively. In this series of tests the highest yield of corn fodder, 3.16 tons per acre, was obtained from the use of 12 tons of fresh barnyard manure per acre.

The cost of producing a bushel of oats at Ottawa, disregarding the value of the straw, is estimated at 21.7 cts., and the cost of producing a ton of hay at $3.93. It cost $1.64 to produce 1 ton of corn silage in the silo, and $21.73 to put the yield of an acre of corn, 13.25 tons, into the silo.

The yields of different grain mixtures are reported without comment.

Waverly oats sown in drills 7 and 14 in. apart did not show a difference in quality, but the yield in grain and straw was slightly in favor of the wider drills. Canadian Thorpe barley sown in the same way gave a noticeably better quality of grain from the drills sown 7 in. apart, while the weight of straw and grain produced was largest from the wider drills. Two lots of well-cured new hay in the mow lost 4.3 per cent in 113 days in one case and 5.1 per cent in 144 days in the other.

The yields for 3 years of wheat, oats, and barley from different qualities of seed are shown in a table, but no conclusions are presented. The results of a fertilizer experiment with corn show that an application per acre of 500 lbs. of complete fertilizer, in addition to a dressing of barnyard manure, gave an increase in the yield of 4 varieties of corn of about 3 to 5 tons per acre, while an application of 250 lbs. gave an increase of about 1.5 to 3.5 tons.

The results of a series of rotation tests in progress at several farms are given in tables.

Report of the Upper Peninsula Substation for the year 1903 [Field corps], L. M. Geismar (*Michigan Sta. Spec. Bul. 28, pp. 3–19*).—An account is given of the weather conditions at the station during the year and of the growth at the station of a number of cereals, forage, and root crops. The season was characterized by an excess of rain and late spring and early fall frost. The yield of oats ranged from 13 to 21 bu. per acre, the latter being given by the variety Black Beauty. The best yield of spring wheat was obtained from Velvet Chaff, 13½ bu. per acre. Of 8 varieties of barley tested, Bonanza led with a yield of 35 bu. of grain per acre. Silver

King yielded 34 bu. per acre, and Beardless 30 bu. Spring rye yielded at the rate of 35 bu. per acre.

Owing to the excessive wet weather field peas grew largely to vines. Many of the peas shelled out before they could be properly cured. Golden Vine produced the heaviest yield of vines, 5,060 lbs. This variety, which it was claimed would attain an average length of 3½ ft., actually reached an average length of 9½ ft. at the station. Several varieties of corn were tested, but none matured. Flax yielded at the rate of 16 bu. of seed per acre. Hungarian millet and alsike clover produced the largest yield of forage per acre, each yielding over 8,000 lbs. An instance is cited in which a luxuriant growth of sand vetch apparently smothered out quack grass. The New Era cowpea reached a height of 16 in. before being killed by frost.

Of soy beans tested Ito San, Medium Early Black, and Ogemaw made the best showing. These blossomed and produced pods, but none of the seed ripened. Dwarf Essex rape and Thousand Headed kale were very successful at the station. The rape produced seed at the rate of 760 lbs. per acre. Of 20 varieties of potatoes tested, Sir Walter Raleigh led in yield. Experiments were made to determine the relative value of fall and spring planting, of spraying potatoes, and of hilling and level culture. Whole potatoes planted in the fall from 2 to 5 in. deep produced practically as good yields and more marketable potatoes than when the same varieties were planted in the spring. Cut potatoes planted in the fall did not give such good results. Many of the pieces rotted and the sprouts appeared weak.

Spraying potatoes with Bordeaux mixture was without benefit during the season, the unsprayed potatoes giving slightly better yields. Level cultivation resulted in larger yields than hilling. Sugar beets grown at the station gave an average sugar percentage of 16.4 and 86.4 purity. Some figures are given showing the shrinkage in beets shipped from the station to a sugar-beet factory at Menominee and to the agricultural college. The loss varied from nothing to 5½ per cent.

The Woburn pot culture experiments in 1902, J. A. VOELCKER (*Jour. Roy. Agr. Soc. England, 64 (1903), pp. 348–364, figs. 9*).—Previous results in this series of experiments are noted in E. S. R., 14, p. 28.

The Hills experiments.—The action of different compounds of manganese at the rate of 2 cwt. per acre on wheat and barley is reported. The insoluble compounds were mixed with the upper 4 lbs. of soil in the pots before sowing the grain, and the soluble compounds were applied in a water solution the day after sowing. The black oxid of manganese (MnO_2) and the carbonate of manganese caked the surface soil and turned it to a dark-brown color. In the wheat experiments the chlorid and the nitrate produced a good color in the plants, while the iodid distinctly retarded germination and growth.

Excepting the pots receiving manganese nitrate and manganese phosphate, the untreated pots in general produced as good plants as any of the others. Seeds soaked for 15 minutes in a 10 per cent manganese-iodid solution were very much reduced in vitality, while soaking in a 5 per cent solution did comparatively little injury, and soaking in a 1 per cent solution apparently gave an increase in yield. The phosphate, chlorid, sulphate, and red oxid (Mn_3O_4) gave each an increase in yield. The nitrate increased the yield of straw but gave less grain than the untreated pot, and the iodid largely reduced both grain and straw.

In the experiments with barley the black oxid, the carbonate, and the sulphate retarded the coming up of the plants. The carbonate, the sulphate, and the iodid pots gave plants inferior to those grown in untreated soil. Soaking the seed in a 10 per cent manganese-iodid solution was less harmful than with wheat. The yields show that the 2 oxids gave no increase in either grain or straw, but that all other treatment had been beneficial. The iodid in this case produced no injurious effects, and the same result was observed with sodium iodid in 1900. The author states that

the iodids may have been washed down and thus rendered harmless to barley, which is a surface feeder.

Miscellaneous experiments.—Twenty-four grains of a sample of wheat badly affected with smut were soaked in water at a temperature of 50 to 55° C. for 15 minutes and sown and compared with 24 untreated grains from the same source. The plants from the untreated seed produced only 10 sound grains, while those from the treated seed yielded over 900 grains with only about 3 per cent of them affected with smut. This method of treatment also gave good results with barley.

Soil studies are being conducted for the purpose of determining whether lime restores fertility by supplying a necessary constituent to the soil, by neutralizing the acidity, or by its effect upon the physical condition, and further to ascertain the nature of the acidity formed in the soil. The history of the soil under investigation is given, and the observations which suggested this line of work are described.

In studying the effects of lime a series of soil samples were continuously treated with the following solutions, each one used for the treatment of a particular sample: Distilled water, nitrate of soda, sulphate of ammonia, and muriate of ammonia. The leachings were analyzed, and while the work is not completed at present, the observations so far made are summarized. The distilled water passed through the soil slower than any of the solutions and was largely retained. The nitrate of soda solution often retained water on the surface by forming a hard surface crust, while the solutions of sulphate of ammonia and muriate of ammonia also hardened the surface of the sample, but the drying of the soil resulted in large fissures through which the liquid could pass more quickly into the lower portions of the sample than in the other tests.

The distilled water removed comparatively little organic matter from the soil, while the first leachings obtained from the samples treated with the solutions of ammonia salts were deeply colored. The removal of lime, as well as that of magnesia, was smallest with the water and increased with nitrate of soda, sulphate of ammonia, and muriate of ammonia, in the order mentioned. The rate of removal with muriate of ammonia was twice as rapid as with nitrate of soda. Sulphate of ammonia was a less potent factor in removing lime than muriate of ammonia, still more exhaustive than nitrate of soda. The author states that the removal of lime from the soil is most rapid in spring and summer, when nitrification is most active, and that it almost ceases during the winter. This investigation will be continued until the lime is exhausted.

The experiments to determine the nature of the acidity in the soil were begun in November, 1901. Surface soil to the depth of 7 in. was washed with distilled water until it had lost its acid character and was then air dried. A similar sample was exposed to the air for 5 months by being spread out and shoveled over from time to time. In this sample also the acidity practically disappeared through the treatment.

Six plants each of wheat, barley, and oats were grown on these samples and compared with crops produced on ordinary field soil not treated with ammonia salts, on acid soil, and on the same acid soil treated at the rate of 1 ton per acre of calcium chlorid. The object of these tests was to determine whether the injurious effects of soil acidity could be removed by washing, aeration, or neutralization, and whether the different crops were equally affected.

Wheat and barley grew best on the washed soil and oats on the aerated soil. Oats did not seem as sensitive to soil acidity as either wheat or barley. Watering the ordinary field soils with leachings from the acid soil did not give a marked reduction of crop. The results obtained are given in the following table:

Results of wheat, barley, and oats on soil samples of different degrees of acidity.

Soil samples and crops.	Length of straw.	Length of ear	Number of ears.	Number of grains.	Weight of corn.	Weight of straw.
Aerated soil:	*Inches.*	*Inches.*			*Grams.*	*Grams.*
Wheat	22.7	2.93	8	169	5.33	18.19
Barley	13.2	1.91	8	107	4.33	5.55
Oats	14.7	4.20	12	294	10.79	12.99
Washed soil:						
Wheat	16.7	3.44	10	194	7.51	19.54
Barley	16.0	3.00	14	258	10.92	12.24
Oats	11.3	3.94	18	249	8.91	16.18
Ordinary field soil:						
Wheat	25.8	2.66	9	180	6.83	14.48
Barley	12.7	2.50	14	236	10.36	10.85
Oats	18.4	5.10	11	199	8.14	13.52
Acid soil treated with calcium chlorid:						
Wheat	....	....	1	1	.02	.58
Barley	....	....	....	....	....	....
Acid soil: Barley	....	....	1	1	.02	.58

The author believes "that the acidity of the soil brought about by the continual use of ammonia salts, or else the condition of soil consequent on its formation, is the cause of the failure of the land to produce barley and wheat."

In view of the fact that when the acid was removed from the soil it still contained enough lime to produce a healthy crop, the removal of lime from the soil in itself is not considered the cause of failure in crop production. The results further show that the acidity produced by continued use of ammonia salts and the consequent loss of lime from the soil can not be removed by the use of a neutral salt like calcium chlorid, but the author states that this can be accomplished by applications of lime. The acidity seemed to be due, not to soluble mineral acids, but to weak organic acids or to acid salts.

Experiments with crops and stock in the year 1902–3 (*Cambridge* [*England*] *Univ., Dept. Agr., Rpt. Expts. Crops and Stock, 1902–3, pp. 27–79, dgm. 1*).—The work with crops is noted here. Cooperative fertilizer, variety, and rotation tests with hay, root, and cereal crops are reported.

In a series of fertilizer experiments on meadows the greatest increase was obtained from the use of sulphate of ammonia and basic slag, and an application of sulphate of ammonia and muriate of potash produced the second best crop. Sulphate of ammonia gave a larger increase in every instance, but the best results were obtained when it was used in combination with basic slag. The phosphatic and potassic manures were quite effective when used alone, and also produced a considerable increase in yield when used with sulphate of ammonia.

At the university farm 16 varieties of mangels were tested and the chemical composition of the roots determined. Yellow Globe mangels produced the largest crop, but they were deficient in dry matter. Goldfinder and Long Red mangels ranked first in the production of dry matter, and Lion Intermediate, which produced only a moderate yield, stood first in keeping qualities.

Taking all the qualities into consideration, the Golden Globe varieties gave the best results. The analyses reported show a close agreement in the composition of varieties belonging to the same group. The variation in the quantity of dry matter varied in the ordinary mangels from 3 to 3.5 per cent, and this was largely due to differences in the sugar content. The percentage of proteids varied from 0.43 per cent in Crimson Tankard to 0.58 per cent in Goldfinder.

A number of varieties of mangels grown at the Norfolk farms under different soil conditions and fertilizer treatment varied in dry matter from 1.3 to 2.9 per cent.

The results at the different farms show that the best mangel in one district may not be the best in another. The analyses of samples taken from these crops show that on the whole the percentage of sugar is more constant than that of dry matter and that proteids varied more and amids much more than either sugar or dry matter.

In addition to 8 varieties of mangels, 13 varieties of swedes were grown at these farms. The varieties of this crop varied less among themselves than the varieties of mangels. The greatest difference in dry matter between any 2 sorts was 3.2 per cent, and the greatest variation due to soil and cultivation, 1.6 per cent. The percentage of sugar was very constant, ranging from 6.1 to 6.7 per cent. The dry matter of the swedes did not contain so much sugar as that of the mangels.

A comparison in composition of different root crops shows that in general small mangels are richer than large ones, but that there are many exceptions in individual roots, and for this reason it is believed that mangels of both size and quality may be obtained. Seed selection for the improvement of root crops is discussed, and it is pointed out that the percentage of dry matter and its content in sugar and proteids may be increased.

A classification of cultivated barleys is presented. Ten varieties of oats were tested at the university farm and of these Waverly, Giant Eliza, and Thousand Dollar were ripe August 12, the other varieties not ripening until August 20 and 21.

The effect of lodging on the yield of wheat was also studied at this farm, and the results show that very badly lodged grain contained 21 per cent of light kernels and moderately lodged grain 8.8 per cent, as compared with 2.1 per cent from grain which stood up well. A series of rotation experiments conducted for the purpose of showing the effects produced by different manures on crops in rotation are reported from different sections.

Field experiments, F. J. Howell (*Jour. Dept. Agr. Victoria, 2 (1903), No. 4, pp. 298–319*).—Cooperative fertilizer experiments on hay crops were made on 30 different fields. The highest average yield, 3.37 tons per acre, was obtained from an application consisting of 2 cwt. of sulphate of ammonia, 3 cwt. of superphosphate, and 1 cwt. of muriate of potash. This yield was more than double the average yield obtained on the unmanured fields.

The data obtained indicate that phosphoric acid was the most important plant food element to be supplied to these soils. Bone dust as a source of phosphoric acid was not as effective as either superphosphate or Thomas slag. Potash produced an appreciable effect on light, sandy soils, but on stronger soils it did not contribute materially to an increase in yield. Nitrogen in the fertilizer applications gave in general good results, but the author advises that this element be procured for the soils by green manuring with leguminous crops.

The results of fertilizer experiments with potatoes are given in tables and briefly noted. The best yield, 6.46 tons per acre, was obtained from the use of 3 cwt. of superphosphate. The highest increase in yield apparently due to the application of fertilizers, 2.57 tons per acre, was obtained from a complete application consisting of 2 cwt. of nitrate of soda, 3 cwt. of superphosphate, and $\frac{3}{4}$ cwt. of muriate of potash. In the experiments with both potatoes and hay superphosphate appeared as the most effective element.

The data for fertilizer tests with maize grown for fodder indicate that the use of 3 cwt. of superphosphate per acre, increased the yield 2.03 tons, and when 2 cwt. of nitrate of soda were added to the superphosphate the increase was 4.43 tons per acre. With only 1 cwt. of the nitrate in conjunction with the superphosphate the increase was 2.82 tons. The use of potash did not give a marked increase in yield. The results of fertilizer experiments with 11 different forage crops show that the maximum yields in 6 cases were obtained from the use of a complete fertilizer application, but these yields were in general only slightly in excess of those where phosphoric acid and nitrogen only had been given.

Cooperative sugar beet culture tests were made on 156 fields, which gave an average yield of 14½ tons, with about 15 per cent of sugar and a purity of over 81.

The average yields per acre of 14 fields of different forage crops were as follows: Maize 12.83, Amber cane 14.64, Kafir corn 9.67, and Egyptian corn 7.83 tons. In a second test Amber cane, Kafir corn, Egyptian corn, and Planter's Friend yielded from two cuttings 29.30, 28.17, 23.10, and 38.47 tons per acre, as compared with 23.57 tons of maize from one cutting.

Rotation experiments (*Ann. Rpt. West Alabama Agr. Expt. Sta. 1903, pp. 1–7*).—On a series of plats corn and cotton were grown continuously or in rotation with peas and oats. The plats under rotation showed a small increase each year over the other plats. Among 8 varieties of cotton tested Russell Big Boll gave the largest yield, 1,040 lbs. per acre. In a fertilizer test with cotton the plat receiving cotton-seed meal and acid phosphate at the rates of 200 and 240 lbs. per acre, respectively, gave the best returns.

Plant breeding experiments, STEGLICH (*Ber. Tät. Landw. Abt., K. Vers. Stat. Pflanzenkult. Dresden, 1903, pp. 5–9*).—The results with continued inbreeding of rye since 1895 show that the type of head remained constant. Length of stem was also a character transmitted to the progeny, and the short and long stemmed strains were clearly differentiated in the length and compactness of the heads. The short-stemmed strains have the shorter and more compact heads.

The results of crossing experiments indicated that the mother plant exerts the greatest influence on the form of the grain and the male parent on its color. Leutowitz mangel proved much more prepotent than Ovoide des Barres. Characters with reference to the foliage seemed to be independent of the form of the root. Crossing these two types brought forth latent characters of the Leutowitz mangel.

Crossing of cultivated plants, T. JAMIESON (*Agr. Research Assn. Scotland Rpt. 1903, pp. 30–32, pl. 1*).—Two-rowed and 6-rowed barley were sown in alternate rows for the purpose of confirming the principle of self-crossing. Nine intermediate forms are reported to have been obtained, and although the author does not believe the evidence to show that the crossing was general, the intermediate forms are considered as confirming evidence that cereals cross by merely growing side by side. Notes are also given on work with grasses and clovers.

The prospects of cassava starch, H. H. COUSINS (*Bul. Dept. Agr. Jamaica, 2 (1904), No. 3, pp. 49–51*).—A brief account of tests on cassava growing, together with analyses of cassava products.

Corn growing, C. P. HARTLEY (*U. S. Dept. Agr., Farmers' Bul. 199, pp. 32, figs. 23*).—This bulletin points out the possibilities of increasing the yield of corn and discusses the different means by which this may be accomplished. In this connection attention is given to improvement in quality of seed, condition of soil, and methods of cultivation. The treatment of corn lands and the culture of the crop is considered in detail.

The preservation of corn, LOIR (*Agr. Prat. Pays Chauds, 4 (1904), No. 19, pp. 65–79, figs. 4*).—This article discusses the preservation of cereal grains in granaries and silos, by means of chemical reagents, and by treatment with sulphurous acid fumes according to the Clayton process.

Field experiments with flax in 1903, KUHNERT (*Mitt. Deut. Landw. Gesell., 19 (1904), No. 14, pp. 97–100*).—These experiments were conducted by the German Agricultural Society for the purpose of determining the influence on the quantity and quality of flax fiber when either phosphoric acid or potash is used alone and ascertaining the losses of fiber which result when the flax is pulled in the ordinary way and when it is cut. Three cooperative tests are compared. Each test comprised 4 plats of 10 ares each.

The first plat received no fertilizer, the second received either 45 kg. or 50 kg. of Thomas slag, the third received 30 kg. of 40 per cent potash salt or 90 kg. of kainit,

and the fourth received the combined applications of the second and third. The potash plats gave the largest average yields of seed and of long fiber. The phosphoric acid plats also showed an increase in yield, but where the 2 fertilizers were applied together the increase was unimportant. The 2 methods of harvesting gave practically equal financial returns.

Flax wax, C. HOFFMEISTER (*Ber. Deut. Chem. Gesell., 36 (1903), No. 6, pp. 1047–1054*).—A study of the composition and properties of this constituent of flax, which, it is believed, has an important influence on the character of the fiber.

Commercial fertilizers for lupines on new land, A. CARLIER (*Ing. Agr. Gembloux, 14 (1904), No. 8, pp. 338–345*).—Yellow lupines were grown on poor pine lands for the purpose of improving the same and bringing them under cultivation. Commercial fertilizers were applied in different quantities and combinations and the results for 1902 and 1903 are given in tables with brief comments.

All potash fertilizers were readily effective in increasing the yield. The natural phosphate given alone remained inactive, but when applied with kainit the yields were about equal to those obtained from the use of basic slag. Inoculation of the soil acted unfavorably in nearly all cases. The best results were obtained where the potassic and phosphatic fertilizers were applied together. Superphosphate proved very detrimental and its use made it impossible to grow lupines on the soil for several years afterwards.

Report of experiments on the effects produced on thirteen different oats, or mixture of oats, by top-dressings of nitrate of soda, R. P. WRIGHT (*West of Scotland Agr. Col. Rpt. 1901, pp. 79–82*).—Seed of each kind of oats was sown on 2 adjacent plats, one of which received a top-dressing of nitrate of soda at the rate of 1 cwt. and the other at the rate of 2 cwt. per acre. On the average the 2 cwt. of nitrate of soda produced an increase of about 150 lbs. of grain and 3 cwt. of straw as compared with the use of 1 cwt. The application of 1 cwt., however, was proportionately much more effective.

In another experiment charlock and runch weeds in the oat crop were sprayed with solutions of nitrate of soda of varying strengths at the rate of 50 gal. per acre. The quantity of nitrate of soda thus applied per acre was 50 lbs. in a 10 per cent solution, 100 lbs. in a 20 per cent solution, 150 lbs. in a 30 per cent solution, and 200 lbs. in a 40 per cent solution. The extra quantities of nitrate of soda applied from 50 to 100 lbs. produced a very profitable increase in yield. The 100 lbs. dressing produced 360 lbs. of grain and 1.5 cwt. of straw more than the 50 lbs. dressing, and the 150 lbs. dressing yielded 760 lbs. of grain and 5.5 cwt. of straw more than the 100 lbs. dressing; but the limit of profitable employ was apparently reached with the 150 lbs. of nitrate per acre. It is pointed out that this increase in yield may also be largely due to checking the growth of the weeds by this treatment, and that the results in general may point to a possible advantage in applying nitrate of soda in solution to crops by spraying rather than in the form of a dry salt.

Report on the results of an experiment showing the effects of air and soil space on the productiveness of oats, R. P. WRIGHT (*West of Scotland Agr. Col. Rpt. 1901, pp. 75–77*).—The author upon noticing that oat plants growing on the outer edges of plats are better developed than those growing in the center, conducted a series of experiments to ascertain the advantage gained by plants having the greater access to air and light. Accordingly, 5 plats of Banner oats were divided each into 3 oblong sections. The middle section of each plat was entirely inclosed by oat plants except at the 2 ends, while the 2 outer sections had not only bare ground at the ends, but were also adjacent to bare space on one of their sides.

The yields of grain and straw were in favor of the outside sections. The effect of light as influenced by the position of the plats is discussed. The results in general are considered as showing the great value to plants of abundant air, light, and ample soil space.

Reports on experiments on the manuring of potatoes in 1900, R. P. WRIGHT (*West of Scotland Agr. Col. Rpt. 1900, pp. 107–143*).—This work is in continuation of experiments previously noted (E. S. R., 12, p. 937), and the different quantities of fertilizers used are there given. The general conclusions of this year's work are that large crops of potatoes can be grown with the use per acre of 20 tons of barnyard manure alone, of 10 tons of manure supplemented with commercial fertilizers, and also by the use of commercial fertilizers alone. The amount of increase from the use of manures and the resulting profits were found to be largely dependent upon the variety, a strong-growing, productive variety being usually the most profitable.

The increase in yield with manures was entirely due to an increase in the size of the tubers. Light dressings of barnyard manure produced much better results than the same quantities employed as heavy dressings. The use of 10 tons per acre, either alone or with commercial fertilizers, was very remunerative. Commercial fertilizers were more effective when used with light dressings of manure than when given with heavy applications.

The best cooking quality and highest nutritive value were obtained in the crop grown with commercial fertilizers alone, the particular application consisting of 6 cwt. of superphosphate, 2 cwt. of sulphate of ammonia, 1 cwt. of nitrate of soda, and 2 cwt. of sulphate of potash per acre. Heavy dressings of barnyard manure alone produced watery tubers, but light dressings were less injurious, and commercial fertilizers applied with the manure had a tendency to counteract its unfavorable influence upon the quality. Considering both quantity and quality, the use of light dressings of barnyard manure, together with suitable applications of commercial fertilizers, is believed to be the best practice.

Potash in commercial fertilizers given with barnyard manure increased the dry matter and starch content of the tuber and the data indicated that about 84 lbs. per acre furnished in 1.5 cwt. of sulphate of potash was the most profitable quantity. With barnyard manure either high-grade sulphate or muriate of potash should be used, and with commercial fertilizers alone the commercially pure sulphate of potash should be employed. In these experiments sulphate of potash gave the finest quality of tubers, while those grown where kainit was used were much inferior in quality. Muriate of potash produced potatoes intermediate in quality between those grown with sulphate of potash and those grown with kainit. The muriate had similar effects on the quantity when only commercial fertilizers were employed, but with barnyard manure it was sometimes as effective, or even more so, than sulphate of potash. Where commercial fertilizers were applied a top dressing of 1 cwt. of nitrate of soda per acre immediately after the first weeding had no injurious effect on the quality.

Report on experiments on the manuring of potatoes in 1901, R. P. WRIGHT (*West of Scotland Agr. Col. Rpt. 1901, pp. 15–34*).—These experiments are in continuation of those noted in the foregoing abstract, and the results obtained this season confirm the conclusions previously stated.

Report on the winter v. spring application of manures to the potato crop, J. W. PATERSON (*West of Scotland Agr. Col. Bul. 24, pp. 73–82*).—The Scottish Triumph potato was grown on 14 plats under different fertilizer treatment and the results obtained indicate that phosphoric acid, whether in the form of superphosphate or basic slag, should be applied in the drill and that special nitrogenous manures should be included in the fertilizer application for potatoes. It was found that kainit gave better results when applied to the plowed land in the previous winter than when used in the spring, and that the time of application was not so important for sulphate of potash and muriate of potash.

Results of the German potato experiment station in 1903 (*Deut. Landw. Presse, 31 (1904), Nos. 14, p. 109; 15, pp. 118, 119*).—The results with 34 varieties

are reported. A number of the best varieties are described and their starch content and starch production given. The variety President Kruger produced the largest yield but was not so rich in starch as Richter Imperator, Gastold, and White Queen, which yielded well and showed a good starch content. Irene, Sas, Apollo, and Bund der Landwirte gave large yields of tubers high in starch. Up-to-date, Ella, and Mohort are recommended as good table varieties.

Potatoes, L. R. Taft and M. L. Dean (*Michigan Sta. Bul. 214, pp. 18–22*).—An account is given of a test of nearly 150 varieties. The early varieties gave good yields of fine quality. The results with the late varieties, owing to the season, were not so satisfactory. About 70 varieties are briefly described and in some instances the yields are reported. The highest yield among the early varieties, 367.64 bu. per acre, is recorded for Irish Cobbler. This variety was followed by Coos Early with a yield of 316.18 bu. per acre. Among the late varieties, Maggie Murphy has for 8 years given an average yield per acre of more than 200 bu.

The use of rye grass in seed mixtures (*Jour. Bd. Agr.* [*London*], *11*, (*1904*), *No. 2, pp. 105, 106*).—A brief account is given of experiments conducted by the Edinburgh and East of Scotland College of Agriculture on the use of rye grass seed in seed mixtures.

It is a common belief that the failure of certain lands to carry grass is to some extent due to the mixture of seed used. That generally employed consists of a very heavy seeding of rye grass with from 7 to 10 lbs. of clover seed. The results of the first year's trial showed that the quantity of rye grass can be advantageously reduced and the clovers flourished better where the rye grass had only been used in moderation or not at all. The results thus far obtained clearly indicate that overseeding with rye grass is an important factor in preventing the growth and development of clover.

The influence of different-colored light on the growth of the sugar beet (*Illus. Landw. Ztg., 24* (*1904*), *No. 24, pp. 268, 269, figs. 3*).—Sugar beets were grown under white, yellow, blue, and red glass and compared with specimens grown in the open. The weight of the leaves and roots was ascertained in the beginning of the experiments, August 1, and again on October 9 and November 13.

Average weight of leaves and roots of sugar beets grown under different-colored light.

Date.	Leaves.				Roots.			
	White light.	Yellow light.	Blue light.	Red light.	White light.	Yellow light.	Blue light.	Red light.
	Grams.	*Grams.*	*Grams.*	*Grams.*	*Grams.*	*Grams.*	*Grams.*	*Grams.*
August 1	371.7	313.3	356.7	556.7	165.2	175.9	171.2	298.5
October 9	441.7	745.0	115.0	408.3	623.3	400.0	322.7	348.3
November 13	360.7	270.0	78.3	186.7	654.0	554.0	313.3	362.0

The sugar content was highest in the beets grown under blue glass, but the general results indicate that the use of light of a certain color can not be of economic importance.

Report on experiments with sugar beet in 1902 and 1903, J. W. Paterson (*West of Scotland Agr. Col. Bul. 21, pp. 36–40*).—Experiments with sugar beets were made in 1902 to test the quality of roots grown in the West of Scotland. The beet crop followed oats and the land was prepared as for turnips. Ten tons of fresh barnyard manure, together with 4 cwt. of superphosphate, 2 cwt. of kainit, and 1 cwt. of sulphate of ammonia were applied and the crop was top-dressed later with 1 cwt. of nitrate of soda per acre. Analyses of the samples from the crop were compared with those of beets grown in Germany, and are considered as showing a favorable comparison. The beets contained 16 per cent of sugar, with a purity of 87.95.

In 1903 one acre of beets was grown with the same fertilizer treatment and method of cultivation. The yield obtained was 13 tons 19 cwt., and the results of analyses confirm those of 1902. It is concluded that the West of Scotland can produce as good beets as other parts where beet growing is a regular industry.

Note on the experimental sugar-cane station at Samalkot, Gódávari District, C. A. BARBER (*Dept. Land Records and Agr., Madras, Vol. II, Bul. 48, pp. 269–272*).—This station has been established for the study of cane diseases and of cane cultivation generally. Experiments are being conducted to determine if by any particular method of planting and cultivation healthful canes may be grown, and to test some of the more economical practices in connection with sugar-cane culture in other countries. Directions are given for the culture of the Red Mauritius cane, one of the new varieties distributed by the station.

Investigation of the culture of tobacco, G. MALYETZ (*Report of the Experiment Tobacco Plantation of the Lokvitz Agricultural Society for the years 1898–1902. Ministry of Agriculture and Imperial Domains*).

Report on experiments on the manuring of turnips in 1900, R. P. WRIGHT (*West of Scotland Agr. Col. Rpt. 1900, pp. 63–87*).—These experiments have been previously described, and earlier results have been noted (E. S. R., 13, p. 243). The conclusions drawn are similar to those reported for 1901, and given in the following abstract.

Report on experiments on the manuring of turnips in 1901, R. P. WRIGHT (*West of Scotland Agr. Col. Rpt. 1901, pp. 55–72*).—The results obtained in previous years have been noted (E. S. R., 13, p. 243). This year the experiments were carried out on 21 farms and the objects of the work were mainly to determine the best method of applying nitrate of soda, and the quantities of kainit and superphosphate most profitably given to the turnip crop. These substances, together with sulphate of ammonia, were applied in different quantities and combinations; and the use of barnyard manure at the rate of 10 tons with 5 cwt. of superphosphate per acre, or at the rate of 20 tons applied alone, was also tried.

The results obtained indicate that where nitrate of soda is the sole source of nitrogen, one-half should be given in the drill and the rest as a top dressing after thinning. When the entire quantity was applied either in the drill or as a top-dressing, the results were much less satisfactory; but of the 2 methods, application in the drill seemed preferable. It was found that sulphate of ammonia as the only source of nitrogen was more effective in some seasons than nitrate of soda. The most profitable returns were obtained where one-half the nitrogen was given in the drills in the form of sulphate of ammonia and the remainder as a top-dressing in the form of nitrate of soda.

The omission of potash from the fertilizer application caused a great reduction in yield. Kainit at the rate of 2 cwt. per acre in the fertilizer application was sufficient to give a large increase. The maximum quantity to be given profitably with other fertilizers is believed to be about 4 cwt. per acre. It was shown that 4 cwt. of superphosphate per acre is frequently sufficient for turnips, and that more than 6 cwt. is not likely to be profitable.

The tests further demonstrated that turnips can be grown with barnyard manure or with commercial fertilizers, but that generally the use of both together is likely to be more satisfactory. The plat receiving 10 tons of manure and 5 cwt. of superphosphate yielded on an average 23 tons 8 cwt. of good turnips per acre. Applications of commercial fertilizers when not well balanced, and heavy applications of barnyard manure alone, had a tendency to reduce the quality and to render the crop more subject to disease. Where barnyard manure was applied with superphosphate the quality was not so much reduced, and the yield was also greater.

Report on the relative effects of superphosphate and basic slag upon the feeding quality of turnips, J. W. PATERSON (*West of Scotland Agr. Col. Bul.*

23, pp. 65–70).—Experiments were carried out in 1901 to determine whether superphosphate or basic slag produced the better quality of turnips, and a repetition of the work was made on 3 farms in 1902. The results of both years indicate that roots manured with basic slag are better for feeding sheep than those grown with superphosphate. The slag crops were the lighter, but the deficiency in yield was more than counterbalanced by the feeding quality.

Nitrogen in wheat grains and their size in dependence on precipitation and temperature, V. A. KHARCHENKO (*Izv. Moscov Selsk. Khoz. Inst.* [*Ann. Inst. Agron. Moscou*], *9* (*1903*), *No. 3, pp. 304–311*).—The author examined 12 varieties of wheat, 7 winter and 5 summer varieties, raised during the 5 years 1898–1902. He found that the winter wheats contained less nitrogen than the summer wheats except during the year 1898, when the winter wheat showed a higher percentage, this exception being accounted for by the fact that in 1898 the winter crops were poor while the summer wheats were good; that the greater the annual precipitation the less the amount of nitrogen in the winter wheat; that there is a direct ratio between the temperature and the percentage content of nitrogen in the winter wheat, i. e., the hotter the summer the greater the nitrogen content, the anomalous year 1898 presenting again an exception.

In general, the author's results are in agreement with those commonly found in agricultural literature and are at variance with the contrary results recently published by B. A. Vlasov.—P. FIREMAN.

Wheat in Canada, W. SAUNDERS (*Canad. Mag., 1904, Apr.; abs. in Science, n. ser., 20* (*1904*), *No. 501, p. 183*).—Wheat from Dunvegan on Peace River, 414 miles north of Winnipeg, weighed 64 lbs. per bushel. Ladago wheat from Fort Simpson, 818 miles north, weighed 62½ lbs. The period of growth varied from 101 to 108 days.

HORTICULTURE.

Report of the South Haven Substation for 1903, T. A. FARRAND (*Michigan Sta. Spec. Bul. 27, pp. 36*).—The work here reported consists largely of the results of tests in continuation of those previously reported (E. S. R., 15, p. 38) of a large number of orchard, small fruits, and nuts grown at the South Haven Substation. A heavy crop was secured during the year of European plums, and good average crops of cherries, apples, and pears. Light crops were obtained of peaches, grapes, quinces, and Japan plums.

With a number of the fruits comparative experiments were made to determine the relative value of dust and liquid sprays for the control of insects and diseases. A thorough test was made of these 2 methods on apples and plums for curculio and brown rot. Generally speaking, the cost of preparing and applying the dry Bordeaux mixture according to station methods was more expensive than liquid Bordeaux. The dry Bordeaux, however, could be applied in about one-third less time, and upon very rolling, hilly locations one horse could do the work of 2 or 3. The liquid spray could be used with or against the wind, while the dust spray could not be used against the wind at all and was most effective when there was little or no wind and the foliage was wet from dew or rain. In no instance did the dust stick as well as the liquid spray.

"Both methods gave excellent results in controlling the codling-moth worms in apples, and dust spraying, using formula No. 1 [lye, sulphur, copper sulphate, and Paris green], proved superior to Bordeaux mixture and arsenite of lime in controlling the curculio in the plum orchard, and seemed to control the brown rot fully as well. Upon very close observation it was found that the fine particles of dust would stick to the waxy bloom of the fruit, while with liquid, unless very heavy with lime, the solution would run off of the plums as though they had been greased. In summing up the results obtained in this season's test, it would not seem advisable to change

from the older method to the new, until the latter has been further tested, improved, and perfected, except upon plums and cherries."

The usual descriptive notes and data on yields are given for 16 varieties of raspberries, 11 of blackberries, 7 of currants, 9 of gooseberries, 19 of grapes, 23 of cherries, 43 of plums, 43 of peaches, 42 of pears, 130 of apples, 9 of crabapples, 5 of quinces, and a number of varieties of chestnuts, filberts, pecans, Japan walnuts, and English walnuts.

A thinning experiment with plums was made to determine whether regular thinning would induce annual crops. In 1902 the fruit of trees of Burbank and Abundance were thinned to stand 2 in. apart, and the results compared the following year with trees which had not been thinned. The trees thinned in 1902 showed no more blooms in 1903 and had no more fruit than the trees which had been left unthinned.

The best results were secured in marketing large fancy plums in 4-basket tomato crates, using the $\frac{1}{3}$-bu. basket for the smaller kinds and the 16-quart crate for the blue Damsons. Peach-leaf curl was again entirely controlled at the stations by the use of copper sulphate solution at the rate of 2 lbs. to 50 gals. of water. In this connection it is stated that it is essential that the first spraying be given before the buds swell. No difference could be observed in the control of the disease whether Bordeaux mixture or copper sulphate solution was used.

In order to determine the effects of heavy rain immediately after applying copper sulphate solution for peach-leaf curl, the trees in one experiment were thoroughly drenched with pure water an hour after the solution was applied. No difference was observable in the amount of leaf curl on trees drenched and on those not drenched. The conclusion is drawn that the action of copper sulphate in destroying the spores of the leaf-curl fungus is almost instantaneous. As a result of tests for a number of varieties of cover crops for orchards, the author states that vetch has proved one of the most valuable plants for cover-crop purposes ever tested at the substation. Clover came next in value.

Report of the Upper Peninsula Substation for the year 1903 [Horticulture] L. M. Geismar and C. D. Smith (*Michigan Sta. Spec. Bul. 28, pp. 20–35*).—The horticultural work of the season consisted for the most part of tests of a number of varieties of carrots, ruta-bagas, turnips, parsnips, beets, peas, beans, sweet corn, squashes, pumpkins, tomatoes, radishes, lettuce, spinach, salsify, kohl-rabi, onions, cabbage, some herbs, and other miscellaneous crops, including strawberries and orchard fruits. Very good yields of strawberries were obtained during the season notwithstanding the occurrence of frosts during the blooming period. Partly grown fruit appeared to be more tender than blossoms. Brief descriptive notes are given of many of the vegetables and fruits grown.

Horticultural work at the Canadian experiment stations, W. T. Macoun, W. S. Blair, S. A. Bedford, A. Mackay, and T. A. Sharpe (*Canada Expt. Farms Rpts. 1903, pp. 89–104, 107–111, 114–121, 299–309, 339–351, 375–384, 389–392, 412–427, pls. 5*).—The authors give an outline of the horticultural work they have respectively carried on during the year at the Central Farm and the four substations in Canada. As in preceding years (E. S. R., 15, p. 149), extensive trials of varieties of vegetables, fruits, shrubs, and flowers are reported.

At the Central Farm a shipment of apples in cold storage to Glasgow was made. The shipment consisted of 10 boxes of North Star and 80 boxes of Duchess. The net returns averaged about $1.40 per bbl., which was considered satisfactory. The details of the shipment are recorded at length. Descriptions are given of a number of seedling fruits which growers have sent in to the Central Farm. In order to show the individuality of trees, a table is given showing the production each year for 5 years of individual trees of 4 varieties of apples. Some trees yielded 2 to 4 times as much fruit as others.

Some data are given on the growth of horse beans, soy beans and hairy vetch, when planted at different dates as cover crops in the orchard. All proved satisfactory. Variety tests are reported with sweet corn, tomatoes, peas, cabbage, onions, squashes, beans, parsnips, lettuce, turnips, etc. Sparks Earliana has proved one of the most satisfactory early tomatoes grown. An article by Mr. Macoun on growing vegetables in a cheese-cloth inclosure has been noted from another source (E. S. R., 15, p. 673).

At the experimental station in Nova Scotia Mr. Blair reports Alaska and Station as the two best early peas to grow. Tomatoes at the same station, staked and pruned to one stalk, produced ripe fruit earlier and were less affected with rot than when allowed to run untrained over the ground. The yield of fruit, however, was not so large. Sparks Earliana, Bond Early Minnesota, Early Ruby, and Extra Early Advance were the best of the varieties tested.

Mr. Bedford, of the Manitoba Station, gives descriptions of 15 varieties of cross-bred apples which fruited for the first time at the station during the season. Fall sowing of tree seeds has been found to give very satisfactory results at that station. Bush forms of squashes do better than the running varieties. Extra Early Orange Marrow is the best substitute for a pie pumpkin yet tested.

Descriptions are given of 49 varieties of apples, 21 of pears, and 10 of plums which fruited for the first time at the station in British Columbia.

Experiments with manures and fertilizers on different varieties of asparagus and raspberries, A. T. JORDAN (*New Jersey Stas. Bul. 173, pp. 20*).—The author has summarized the results secured in experiments extending over a number of years at the station in the growing of asparagus and raspberries with commercial fertilizers in comparison with manure. The results secured in individual years have been noted from time to time (E. S. R., 15, p. 152). The work includes a study of the relative value of barnyard manure, a complete commercial fertilizer, the same commercial fertilizer plus bone and potash, and the same commercial fertilizer plus bone, potash, and nitrate of soda. Certain cultural features have also been studied.

The combined results of 6 years' work with asparagus place Palmetto at the head of the list of 8 varieties tested as regards disease resistance, early and total yields, and money returns. Donald Elmira stands second in early and total yields. One-year-old roots have been found fully as satisfactory for transplanting as two-year-old roots.

As regards fertilizers, the largest and cheapest yields have been secured by the use of commercial fertilizers alone. The manured plat stands second in yield, but the cost of production has been greater on the manured plat than on any of the others. The use of complete commercial fertilizer alone has been only about one-third as expensive as the manure, while the total yield has averaged 2 per cent better. The addition of bone and potash or bone, potash, and nitrate of soda to the complete fertilizer has not resulted in increased yields, and while more expensive than complete fertilizer alone has been only about one-half as expensive as manure. As compared with complete fertilizer alone manure had a value of 42¾ cts. per ton as a fertilizer for asparagus. The conclusions of the author relative to asparagus are in part as follows:

"The selection of varieties in planting is very important. Palmetto, a disease-resisting variety, gives a yield exceeding that of the Elmira, second in order, by 32 per cent, in the average of six crops, and by nearly 36 per cent in crop of 1903. The cash value by which Palmetto exceeds any other variety equals $111.01 and $221.88, for the average crop and that of 1903, respectively . . . Manure at $1.50 per ton, 20 tons per acre, is the most expensive method of supplying plant food. The returns per dollar of cost are the lowest of any of the four methods of fertilizing used."

The work with raspberries is summarized for the 3 red varieties tested. Of these, Cuthbert stands at the head as regards average yield, and is considered by far the

best market berry of the three. Marlboro is valuable for earliness; Turner is discarded. The largest yield of early fruit has been obtained by the use of manure, but the largest total yield has been obtained on the plat receiving complete commercial fertilizer plus bone and potash. On the basis of cost, however, each dollar invested in manure has returned $1.60 and $6.90, respectively, in early and total yields, each dollar invested in complete fertilizer has returned $5.94 and $27.15 in early and total yields, respectively; each dollar invested in complete fertilizer plus bone and potash has returned $2.46 and $17.63 in early and total yields, respectively; and each dollar invested in complete commercial fertilizer plus bone, potash, and nitrate of soda has returned $2.31 and $11.51 in early and total yields, respectively.

As with the asparagus, the cheapest fertilizer for raspberries, considering the cost and yield, has been the complete commercial fertilizer. The addition of nitrate of soda at blooming time has been without value for this fruit. The author concludes that manure at $1.50 per ton is the most expensive of the four methods of fertilizing practiced with raspberries, while the total yields and the returns per dollar of cost are the lowest obtained.

German asparagus culture, H. W. HARRIS (*Dept. Com. and Labor, Mo. Consular Rpts. 1904, No. 286, pp. 85, 86, fig. 1*).—An account is given of German methods of growing asparagus in the region of Baden. It appears that the roots are planted 4–5 ft. apart in rows about that same distance apart. Stable manure is used in preference to commercial fertilizers and the ground kept mounded up around each hill 10 to 14 in. high. A fair crop is secured about the fourth year, but the field is at its best from 8 to 12 years after planting.

An old asparagus bed, W. S. CAMPBELL (*Agr. Gaz. New South Wales, 15 (1904), No. 4, pp. 322, 323*).—An asparagus bed in flourishing condition 60 years old is described.

Comparative tests of standard varieties of onions, H. FIELD (*West. Fruit Grower, 15 (1904), No. 9, pp. 18, 19*).—The results are given of tests of a number of varieties of onions grown in Iowa. In some instances 2-year-old seed was used. It was estimated that at 50 cts. a bushel the increased money value from the use of 1-year-old seed rather than 2-year old amounted to $140 per acre in the case of the Red Wethersfield variety. Notes are also given on tests of a number of varieties of cabbages and sweet corn. Dahlias were grown from seed nearly as quickly as from bulbs.

Notes from a seedman's trial grounds, H. FIELD (*West. Fruit Grower, 15 (1904), No. 7, pp. 14, 15*).—The results of tests of varieties of lettuce, table beets, peas, string beans, sweet corn, and a number of miscellaneous farm crops are recorded.

Tomatoes, L. R. TAFT and M. L. DEAN (*Michigan Sta. Bul. 214, pp. 13–17*).—Descriptive and cultural notes are given on 72 varieties of red and 8 varieties of yellow tomatoes grown at the station during the year. Relative to the advantages of staking tomatoes the authors state that tomatoes thus trained can be planted much closer, the fruit is of better quality, and in excessively wet years it is possible to ripen a good crop of fruit, when if planted in the ordinary manner it might not mature at all. Little difference was noted in the time of maturing of tomatoes whether from field-grown seed or from seed started in the greenhouse and the seedlings transplanted to the field.

Further studies in crossing peas, stocks, and beans, E. TSCHERMAK (*Ztschr. Landw. Versuchsw. Oesterr., 7 (1904), No. 8, pp. 533–638*).—A detailed account of the results secured in crossing experiments with a number of varieties of peas, stocks, and beans, with a discussion of the results obtained, with reference to the Mendelian theory of heredity. Reference to earlier work along the same lines may be found in E. S. R., 13, p. 745.

Forcing with carbonic acid, DEMOUSSY (*Jardin, 18 (1904), No. 418, p. 221*).—The author notes an experiment in which lettuce was grown under 4 bell jars. With

2 of the bell jars a small stream of air was circulated through; in the other 2 bell jars air containing 5 times the usual amount of carbonic acid was forced through. At the end of 24 days the 4 plants in each of the pots in which air only had been admitted weighed 21 and 24 gm., respectively, while the 4 plants in each of the pots to which carbonic acid had been added weighed 50 and 60 gm., respectively. The author believes that carbonic acid may be valuable as an aerial fertilizer for market gardeners in intensive culture.

Edible fungi, C. H. PECK (*New York State Mus. Bul. 75, pp. 27–34, pls. 3*).—Technical descriptions are given of a number of species of edible fungi, together with notes on their distribution, habits, and uses.

The fruit trade with foreign countries (*U. S. Dept. Agr., Bureau of Statistics Crop Reporter, 6 (1904), No. 5, pp. 38–40*).—Statistics are given of the imports and exports of fruit for the United States during the years 1903 and 1904. For the fiscal year ended June 30, 1904, the fruit exported from the United States was valued at $20,348,299. The fruit imported during the same period had a value of $18,964,930. Bananas were the largest item of importation, being valued at the ports of the producing countries at $7,000,000 to $8,500,000. Next in importance to bananas in the import fruit trade are lemons, at the value of $3,000,000. Apples and prunes are the fruits most extensively exported. The value of the apples exported in 1903–4 amounted to $8,237,894. The value of prunes was $3,410,497. Together these 2 items make up more than half the value of the fruits exported from the United States. Considerable information is given as to the countries from which the various fruits are imported and to which domestic fruits are sent.

Report of the fruit experiment stations of Ontario, L. WOOLVERTON ET AL. (*Ontario Fruit Expt. Stas. Rpt. 1903, pp. 83, figs. 33*).—In addition to an account of a visit of inspection to the numerous fruit experiment stations established throughout Ontario and reports by a large number of growers on the success which they have obtained with different fruits in their respective localities, original descriptions and illustrations are given of 7 varieties of apples, 4 of grapes, 1 of peaches, 3 of pears, 6 of plums, and 1 of raspberries. An effort is being made to identify all of the varieties of fruits now grown in the Province, and these illustrations and descriptions are contributions to that end. An account of other work along the same line may be found in E. S. R., 15, p. 473.

Apple growing in Tasmania, J. KNIGHT (*Jour. Dept. Agr. Victoria, 2 (1904), No. 8, pp. 744–748*).—An account of the methods of planting, cultivating, and handling apples in Tasmania.

The avocado in Florida; its propagation, cultivation, and marketing, P. H. ROLFS (*U. S. Dept. Agr., Bureau of Plant Industry Bul. 61, pp. 36, pls. 4, figs. 9*).—The author presents a summary of present knowledge of the avocado and indicates lines of improvement. The word avocado is preferred for this fruit, which is also known as alligator pear, aguacate, etc. It is at present grown only to a limited extent in southern Florida. It is being shipped to northern markets as a salad fruit and is gaining in popularity.

Some figures are given showing the great variation in fruit and yields obtained from seedling trees. Of an orchard of 160 trees, 5 years old, 47 trees bore no fruit at all; 41 trees bore from 1 to 12 fruits; 22 bore a crop of more than 12 fruits, 9 of which bore a total of 595 fruits, or slightly over half the crop. Of the 63 trees that have fruited in the orchard only 2 combined good qualities in such a way as to be of special merit.

In order to avoid this great variation in quality of fruit and yield the use of budded and grafted trees is advocated, and these methods of propagating are described. The bulletin contains directions for marketing the fruit and an account of the diseases affecting it. Budding is considered the most desirable way of propagating, and crown working is preferable to top working. Pear and oblong shaped fruits are most desir-

able with the color preferences as follows: Yellow, scarlet, green, brown. Fruit which ripens during December or later brings the highest prices.

Improving fruits by bud selection, A. T. JORDAN (*Amer. Agr., 74 (1904), No. 9, p. 160*).—A large number of instances are cited to show the variation in productiveness, earliness, and quality of a number of different trees of the same variety of fruit, thus leading to the conclusion that propagation by budding should be done by selecting buds from those trees only which show decided merit.

Fruit without blossoms, W. F. NEHRING and E. C. JOHNSTON (*West. Fruit Grower, 15 (1904), No. 7, p. 2*).—The authors in separate articles cite several instances of apple trees which bear fruit without blossoming. Mr. Nehring states that "seedless, coreless, and bloomless apples are all one and the same thing, and have been known for 40 years or more." He gives the addresses of two gentlemen who can furnish buds for grafting, and states that these trees must be planted among other trees to be pollenized.

The olive growers' convention at Sfax, DELOUPY, POUGET, and TRABUT (*Le concours oléicole de Sfax. Govt. Gen. Algeria, 1904, pp. 49, figs 28*).—An account of the olive industry at Sfax, with special reference to the manufacture of olive oil. Descriptions and illustrations are given of much of the machinery used in the manufacture of oil. Notes on the preservation of olives, on the treatment of olives for the prevention of certain diseases, etc., are included.

Report of new fruits, W. T. MACOUN (*Ontario Fruit Growers' Assoc. Rpt. 1903, pp. 121–124, fig. 1*).—Descriptions are given of a number of varieties of seedling fruits of pears, plums, peaches, grapes, and raspberries which have been sent to the author for examination. An illustration is given showing some of Doctor Saunders' hybrids from *Pyrus baccata*.

New fruits, H. L. HUTT (*Ontario Fruit Growers' Assoc. Rpt. 1903, pp. 118–120*).—The author describes a number of seedling apples, peaches, plums, and gooseberries which are considered of merit.

Influence of grafting on the posterity of the scion, JURIE (*Jardin, 18 (1904), No. 413, p. 221, figs. 2*).—Seed saved from an eggplant grafted on the tomato produced a vegetable monstrosity, which is figured. This result is believed to suggest asexual hybridity, and to indicate promising results for this method of hybridizing.

Successful new grafts in 1904, L. DANIEL (*Jardin, 18 (1904), No. 419, p. 230*).—A list is given of successful grafts made during the season with 6 families of plants.

Concerning the source of coffee, P. GUIGUES (*Bul. Sci. Pharmacol., 5 (1903), pp. 350–357; abs. in Ztschr. Untersuch. Nahr.- u. Genussmtl., 7 (1904), No. 9, p. 560*).—A descriptive article.

Yerba maté, a substitute for coffee and tea, L. H. AYMÉ (*Dept. Com. and Labor, Mo. Consular Rpts. 1904, No. 286, pp. 56, 57*).—An account is given of the preparation and use in Brazil of the tea obtained from *Ilex paraguayensis*, known as Yerba maté. It is believed that the peculiar bitter and smoky taste of Yerba maté is due to present methods of curing the leaf, and that by the use of iron and copper pans for drying a better quality of product can be secured. Maté is said to have all the good qualities of coffee and tea as a mild, stimulating health beverage, without the disadvantages of either.

Tea manufacturing (*Japan in the Beginning of the 20th Century. Tokyo: Imperial Japanese Commission to the Louisiana Purchase Exposition, 1904, pp. 151–158*).—An account of the history, present condition of the industry, the kinds of tea grown in Japan, and the markets.

A report by the controller of the experiment station, Peradeniya, H. WRIGHT (*Circs. and Agr. Jour. Roy. Bot. Gard., Ceylon, 2 (1903), No. 4, pp. 93, pls. 4*).—This is the first annual report of this station and is devoted mainly to cacao. The station contains about 150 acres and is densely covered with timber. The ground has been platted and an inventory is given of the number and kinds of trees on each

plat. In addition to about 60,000 cacao trees, the inventory shows an abundance of cocoanut, arecanut, crotons, pepper, arnatto, coffee, sapan, Ceara and Castilloa rubber, cardamoms, castor-oil plants, citrionella, nutmeg, orange, lime, and many other kinds of useful trees growing on the different plats, in all 26,746 trees.

At the opening of the station the cacao fungus, *Nectria* sp., had vigorously attacked about 96 per cent of the trees. This has been combated by clearing out shade trees so that the sunlight may penetrate, by excision of the cankered bark, and by spraying with various combinations of copper sulphate and lime or mud. Excision without first letting in sunlight was only partially successful. Spraying systematically reduced the number of pods affected with fungus, but the number of sprayings and best method of application remains to be determined.

Favorable results were secured with cacao by heaping together and partially burning a thick coating of leaves, branches, cocoanut husks, and empty cacao fruits. The final product was then buried, with or without a little lime, in trenches about a foot deep. It is believed this work combined the good effects of draining, root pruning, and manuring. An attempt was made to secure a good curing of cacao seeds which had been fermented inside the pod, and also to obtain clean, marketable seed without fermenting. "In no case did the results obtained justify the change in our method of fermenting and curing. All the seeds which were fermented inside the fruit had to be placed along with the 'black' cacao, owing to the pliable nature and unequal color of the substance of the seed. The seeds which were cured without washing had likewise to be placed with the 'black' cacao; the finished article had a dirty appearance and was very hygroscopic in consequence of the soft pulp around the seeds not being removed, and this in its turn led to the appearance of mold over the seeds. On the other hand, the unwashed seeds had a sweet taste and showed an increase in weight." The various varieties of cacao in Ceylon are described and an account is given of cacao selection and hybridization experiments now under way.

Work in the selection, culture, and curing of cardamoms has been begun, and experimental plats started of a number of fiber plants.

The food of the gods, B. Head (*London: R. Brimley Johnson, 1903, pp. IX+111, pls. 22, figs. 40, charts 3*).—This is a popular account of the early history and culture of cacao, and present methods of cocoa manufacture. Some statistical matter is given showing the production in different countries of the world. A detailed account is given of the model village of Bournville, England, where cocoa is manufactured on a very large scale.

History of cocoa, W. G. Mortimer, trans. by H. B. Gausseron (*Histoire de la coca. Paris: A. Maloine, 1904, pp. 328; rev. in British Med. Jour., 1904, No. 2267, p. 1374*).—This volume, which is an abridged translation of the second edition, gives a concise history of the discovery, characteristics, and uses of cocoa, etc.

Small fruits for 1904, L. R. Taft and M. L. Dean (*Michigan Sta. Bul. 213, pp. 3-12*).—An account of the growth during the season with descriptions of 24 varieties of strawberries, 10 of blackberries, and 3 of cherries. Experiments with cover crops in 1902 indicate that cowpeas have no value as a cover crop in Michigan orchards when sown as late as August 1. Rape and flat turnips proved of doubtful value as cover crops. Crimson clover and mammoth clover were about equally valuable. Both oats and barley proved valuable as cover crops. Both made a rank growth which froze down during the winter and formed a mulch which was of much benefit to the soil. Of these two cereals barley made the stronger growth and is preferred.

Some strawberry notes, F. W. Card (*West. Fruit Grower, 15 (1904), No. 8, pp. 14, 15, fig. 1*).—The author states that in the growing of seedlings the Hunn variety has been used extensively in crosses made and is unusually prepotent. With regard to the sex of the seedlings, it has been noted that where both parents are perfect the resulting seedlings are almost wholly of the perfect kind. If one of the parents is

imperfect the seedlings are likely to be very evenly divided as regards sex. Imperfect blossoms appear to be much smaller than perfect blossoms.

Crosses between Wm. Belt and wild strawberries have given very weak offspring. Strawberries mulched with evergreen boughs came through the winter in better condition and started into growth much better in the spring than when mulched with bog hay.

Strawberries, L. C. Corbett (*U. S. Dept. Agr., Farmers' Bul. 198, pp. 24, figs. 14, map 1*).—Popular directions are given for the propagation and field culture of strawberries with notes on varieties and on forcing strawberries for winter fruit.

Strawberry growing, W. L. Howard (*Ann. Rpt. Missouri State Bd. Agr., 36 (1903), pp. 260–273, pls. 3, figs. 4*).—Complete directions are given for the planting and care of strawberries including directions for irrigating, winter mulching, picking, packing, and marketing.

Dewberry record covering five years at Puyallup (*Northwest. Hort., 17 (1904), No. 9, p. 196*).—A record is given of the number of crates of berries grown and the expenses each year for 5 years for an acre of dewberries. The average net receipts for the years 1899 to 1903, inclusive, were $243.73 per acre per year.

Cranberry production, A. J. Rider (*Ann. Rpt. New Jersey State Bd. Agr., 31 (1903), pp. 102–105*).—A historical account is given of the development of cranberry industry in New Jersey.

The profitable extraction of alcohol from pressed grape husks, A. J. Perkins (*Jour. Agr. and Ind., South Australia, 7 (1904), No. 11, pp. 607–614, figs. 2*).—From analyses made by the author it is estimated that the alcohol retained in the husks of grapes after being pressed is about 4.8 gal. of proof spirit per ton of fruit, or about 12.25 gal. of proof spirit per ton of marc. It is believed that under certain conditions the profitable recovery of this alcohol might be undertaken by systematic leaching in a series of tanks in a manner similar to that employed in the extraction of sugar from sugar beets by the diffusion method, followed by distillation.

With a series of 5 tanks and 5 leachings for each tank, 34.662 tons of fruit which had previously yielded 4.922 gal. of wine averaging 13 per cent of absolute alcohol, an additional 50 gal. of "piquette" averaging 7.4 per cent alcohol, or 13 per cent proof spirit, was obtained.

The fertilization of the vine, A. Cimatti (*La Concimazione della Vite. Bologna: Società Tipografica già Compositori, 1904, pp. 56, figs. 9*).—Some experiments tending to show the value of commercial fertilizers in Italian vineyards are recorded.

How the raisin is seeded, H. A. Crafts (*Home Sci. Mag., 21 (1904), No. 3, pp. 121, 122*).—A description of the process by which raisins are seeded on a commercial scale.

Rubber cultivation (*Planting Opinion, 9 (1904), No. 13, pp. 266, 267*).—An account, taken from the Mysore Gazette, is given by the superintendent of the government gardens at Mysore of the production, spread, and possible utility of the rubber tree *Manihot glaziorii*. Ceara rubber is said to grow remarkably well at Mysore. In 1885, when the first saplings were 5 years old, tappings were made and a small ball of rubber obtained, but the flow of latex at that time was very feeble.

In 1904 a series of tapping experiments were again conducted with these trees, which amply proved that the Ceara tree is quite productive of latex in the climate of Bangalore. From one single tree a yield of 7 lbs. of rubber was obtained in one year, and the tree did not appear to be in the slightest exhausted. This tree was 15 or 16 years old, and was tapped 83 times during the year.

The results of the season's experiments in tapping are believed to show that at 15 years of age and upwards every woody part of the tree, including root-limbs, is well charged with latex. Trees of the same age are not equally productive. The root-limbs are productive of latex when the trunk is nearly exhausted, and vice versa. The latex has been found to flow most freely from 6 to 8 a. m., and, excepting in

wet weather, trees may be safely tapped at short intervals all the year round. Tapping once a week would give a good average return of rubber.

The present crude methods of tapping are considered wasteful and should be replaced by an approved method, using proper tools and implements. The best season for tapping the trunk is from July to January, when the tree is in leaf. "Tapping the bark deeply, or slashing and scoring it obliquely to swell a central stream, fails to produce the best flow of latex, while it undoubtedly injures the tree, but when punctured and scored to the depth of ½ in. in the early morning the flow is usually well sustained for a couple of hours."

The gutta-percha and rubber of the Philippine Islands, P. L. SHERMAN, Jr. (*Philippine Dept. Int., Bureau Govt. Lab.* [*Pub.*], *1903, No. 7. pp. 43, pls. 41, maps 2*).—A study is given of the gutta-percha and rubber industries of the Philippine Islands based upon investigations carried on under the direction of the Bureaus of Forestry and of Government Laboratories, a preliminary report of which was made in the Report of the Forestry Bureau for 1902 (E. S. R., 14, p. 1079).

The trees producing gutta-percha are said to be among the largest and most striking of the forest trees of the islands. The author recognized 10 species, 9 of which belong to the genus Palaquium and one to Payena. The geographical distribution and characteristics of the different trees are given, after which the author describes methods of collecting and marketing their product. The physical and chemical properties of various samples of gutta-percha are shown and notes given on the propagation of the trees. The results of investigation on the propagation of the trees and scientific methods of collecting as worked out in Java and elsewhere are given.

The rubber-producing plants of the Philippines are all vines, no true rubber trees being thus far recognized as indigenous to the islands. Two species of vines are said to be well distributed, *Parameria philippinensis* and an undetermined species, both yielding a good grade of rubber. The methods of collecting rubber are described and the Philippines are discussed as a rubber-producing country through the utilization of natural supplies and through the introduction of foreign species.

Gutta-percha and rubber, P. L. SHERMAN, Jr., (*Philippine Com. Rpt. 1903, pt. 2, pp. 393–411, pls. 41, maps 2*).—This article is essentially a reprint of Bulletin No. 7 of the Department of Interior, Bureau of Government Laboratories, noted above.

Result of trial with patent palm nut cracking machine (*Rpt. Bot. and Agr. Dept.* [*Gold Coast*], *1903, pp. 7, 8*).—An account is given of tests of a machine lately placed on the market for cracking the palm nut. With the assistance of the machine a hundredweight of kernels was prepared for 7 shillings, while the same amount cracked by hand cost 12 shillings. About 19 per cent of the nuts passed through the machine unbroken.

The action of ether vapor in forcing plants, J. LOCHOT (*Rev. Hort.* [*Paris*], *76 (1904), No. 11, pp. 250–252, fig. 1*).—From a number of trials in the use of ether vapor for forcing plants, the author draws the following conclusions: The action of ether varies according to whether the shrubs to be forced have entered a state of winter repose or not. In the first case etherization will advance the flowering period only a few days, while the blossoms will be of equal luxuriance. In the latter case the period of blossoming is hastened a half and the flowering is much more perfect. In a dry atmosphere at 15° C. from 100 to 150 gm. of ether per cubic meter may be employed without danger, and in a humid atmosphere 300 gm. may be used. The duration of the etherization should correspond to the time necessary for the total evaporation of the ether. In a dry atmosphere 24 hours is sufficient, while in a humid atmosphere 36 to 48 hours are sometimes necessary. In a dry atmosphere the temperature ought not to exceed 15 to 18° C., while in a humid atmosphere it may reach 22 to 25° C. without danger. The most striking results have been obtained in the forcing of lilacs. The differences in favor of etherization with snowballs (*Viburnum opulus sterilis*), *Azalea mollis*, and *Deutzia gracilis* were less notice-

able. Etherization is most effective early in the season. After January no benefits are derived from the practice.

Forcing plants by etherization, A. MAUMENÉ (*Jardin, 18 (1904), No. 406, pp. 20-22, figs. 2*).—An account is given of the successful use of ether in the forcing of a number of varieties of lilacs and spirea.

Growing bulbs in Illinois, G. KLEHM (*Amer. Gard., 25 (1904), No. 498, p. 542*).—The author states that since about 1885 they have grown nearly 100,000 bulbs annually, consisting of tulips, narcissi, and lily of the valley. The ground selected was of low, well-drained, deep, black loam and was heavily manured with stable manure. The majority of the bulbs produced were not quite so large as imported bulbs, but in earliness and ease of forcing, the size of flower and length of stem when grown under the same conditions, little if any differences were observable. With the lily of the valley the quality of the flowers, both in size and substance and number of bells, was far in excess of the imported pips.

Begonia culture for amateurs, B. C. RAVENSCROFT (*New York: Charles Scribner's Sons, pp. 90, pls. 4, figs. 13*).—Popular directions are given for the cultivation of begonias under glass and in the open air.

Report of the committee on school gardens and children's herbariums for the year 1903, H. L. CLAPP (*Trans. Massachusetts Hort. Soc. 1903, II, pp. 239-268, figs. 13*).—The character of the work carried on at several schools in Massachusetts in growing vegetables and flowers in school gardens is outlined in more or less detail and illustrated, and a list of the prizes and gratuities awarded for the children's herbariums given.

FORESTRY.

Sylvicultural features of Larix americana, GRACE E. COOLEY (*Forestry Quart., 2 (1904), No. 3, pp. 148-160*).—Attention is called by the writer to the American larch, which, although known to be a vigorous grower, seems to have been neglected by foresters and others. The investigations upon which the paper was based were principally carried on in Hancock County, Maine, but additional observations were reported from a number of points in northern Indiana and elsewhere. The general distribution of the species throughout the western hemisphere is indicated and the characteristics of growth described.

In general the tree is closely associated with swamp localities, although the author states that it grows readily in any situation where there is sufficient freedom of soil and air for its development. The tree does not bear shade well and on this account is not well adapted to a mixed growth. According to a number of measures given the species is of rapid development when compared with other coniferous trees, specimens of 45 years being more than 60 ft. in height and 18 in. in diameter.

The larch fruits abundantly and, if given sufficient sunlight, thrives where many other seedlings would not grow. This is a very important consideration, as the species can only establish itself in ground unoccupied by other trees. A number of points are mentioned which, the author expresses the hope, should be further elucidated by study on the part of foresters, ecologists, and others.

A farm woodlot, F. A. WAUGH (*Massachusetts Sta. Bul. 97, pp. 19, figs. 13*).—A description is given of the woodlot belonging to the Department of Horticulture of the Massachusetts Agricultural College, the author seeking to set forth by concrete example the results of practical forestry under conditions which are typical of nearly the whole of Massachusetts and large areas in neighboring States.

The woodlot in question has been a source from which was obtained stove wood, fencing, lumber, etc., and contains 12.5 acres. The quality of the land is rather better than that which would ordinarily be used as a farm woodlot, but otherwise the conditions are believed to be typical. The species of trees grown in greatest abundance were chestnut, white oak, red oak, hard maple, yellow and white birch, larch, Scotch pine, and hemlock, with small quantities of other species.

The mixture of species in a woodlot is encouraged by the author on account of the easier management and greater variety of forest products. Different portions of the woodlot are illustrated in the photographic reproductions and suggestions given for the improvement of the different tracts by thinning, pruning, planting, etc.

Forest belts and notes on the arboretum, W. T. MACOUN (*Canada Expt. Farms Rpts. 1903, pp. 121–125*).—A brief report is given on the present condition of the trees in the forest belts which are, on the whole, said to be quite satisfactory. A list is given of some of the more important trees, shrubs, and herbaceous perennials growing in the arboretum, and descriptions given of a number which are attractive on account of their foliage, bark, or fruit.

Trees and shrubs, A. MACKAY (*Canada Expt. Farms Rpts. 1903, pp. 384–389*).—A list is given of trees and shrubs which have proved hardy and satisfactory in growth at the Indian Head Farm and which are recommended for cultivation throughout the territories. A list is also given of the species and varieties now under observation, together with the date of planting and notes on relative hardiness.

Exhibit of tree planting on a model prairie farm at the Louisiana Purchase Exposition, G. PINCHOT (*U. S. Dept. Agr., Bureau of Forestry Circ. 29, pp. 8, fig. 1*).—The author describes the open-air exhibit of the Bureau of Forestry, which is designed to illustrate the use of forest trees for windbreaks, hedges, and woodlots in the prairie States. The relative location and extent of woodlots, hedges, and windbreaks have been planned with reference to the actual needs and conditions. Different systems of planting and different species of trees are suggested for mixtures suitable for the different parts of the country.

Practical assistance to users of forest products, G. PINCHOT (*U. S. Dept. Agr., Bureau of Forestry Circ. 28, pp. 2*).—A statement is given of the conditions under which the Bureau of Forestry offers its assistance in the study of problems relating to the selection, testing, handling, seasoning, and preservative treatment of construction and other timbers, and the form of agreement upon which these cooperative investigations are carried on is also given.

DISEASES OF PLANTS.

A soft rot of the calla lily, C. O. TOWNSEND (*U. S. Dept. Agr., Bureau of Plant Industry Bul. 60, pp. 47, pls. 9, figs. 7*).—An account is given of a serious disease of the calla lily which has been under the author's observation since 1899. This disease has made its appearance in various parts of the United States where callas are cultivated and has caused great loss to the growers.

A number of greenhouses where the disease was reported were visited by the writer, who found the callas rotting usually at or just below the surface of the ground. The disease sometimes extends down into the corm, sometimes upward into the leaves, and frequently in both directions. Occasionally it seems to start in the edge of the leafstalk, in the flower stalk, or in the underground part of the corm, but usually it appears at the end of the corm at or near the surface of the ground.

When a diseased corm is cut open the healthy part is found nearly white, while the diseased part has a brownish color and is soft and watery. When the leaves are involved the petioles become slimy without immediately losing their green color and as the disease progresses it extends toward the center of the petiole interfering with the transfer of material between the corm and the leaf, the edges of the leaf becoming pale and later brown. Pale spots becoming brown appear in the leaf blade and finally the whole leaf becomes brown and dead. Sometimes the disease develops so rapidly that the leaf rots off at the base and falls over without losing its green color. When the disease has progressed far enough to attack the flower stalk, the flower turns brown and the stalk without losing its color eventually falls over.

If the conditions for the development of the disease are unfavorable after the corms

are affected, the softened spots will dry up, sinking below the surrounding portion of the corm, and in these places the organism causing the disease will remain dormant until the conditions for its development again become favorable. In this way the disease is carried over from season to season and may be transported over long distances.

A microscopical examination of the affected parts shows an abundance of bacteria and the morphological characters of the organism and its physiological characteristics, as shown when grown on different media and under varying conditions, are described. Comparisons have been made between the organism causing this disease and those known to cause a number of similar plant diseases, but the organism of the calla lily differs very materially from the others and it is proposed, therefore, to call it *Bacillus aroideæ* n. sp., the technical characters of which are given.

The origin and spread of the disease are described, and it is said that the spread from plant to plant within the house seems to be accomplished mainly through the soil. The spread of the disease over long distances is accomplished as described above. The nature of the soil seems to have an influence on the spread of the disease, as soils rich in vegetable matter, filled with humus, and containing a large amount of moisture favor the rapid multiplication of the organisms.

Experiments were conducted with a number of fungicides for preventing the disease, none of which were entirely successful. The application of lime and lime and sulphur retarded the progress of the disease and in a few cases seemed to have entirely eradicated it. As the disease did not seem to be controlled by the usual methods of attention to the soil, it was found that by changing the soil every 3 or 4 years and carefully selecting the corms for planting, the disease may be held in check. The organism causing this rot was found able to attack a large number of raw vegetables, producing a soft rot in them, and on this account care should be taken not to throw any decayed or partly decayed callas where vegetables are stored or grown. It does not attack tree fruits readily, and is not likely to produce fruit rots.

Diseases of ginseng, J. M. VAN HOOK (*New York Cornell Sta. Bul. 219, pp. 165–186, figs. 25*).—It has been generally claimed that the ginseng plant is practically free from fungus enemies, and, while this may be true in a wild state, a single season's study of the cultivated plant has shown that it is subject to a number of very serious diseases. One of the most destructive is the wilt of the old ginseng plants, which may be readily recognized by the wilting of the foliage and the discoloration of the roots and rootstocks when observed in section. This disease is attributed to a species of Acrostalagmus, which, while slightly differing from *A. albus*, is not considered sufficiently different to warrant its description as a new species. The investigations so far carried on with this disease seem to indicate that it spreads through the soil and that probably by the selection of resistant varieties it can be most profitably combated.

Wilts of seedlings are also described, one of which results in the damping off of young plants caused by attacks of Rhizoctonia. In a second, which is called an end rot, the lower end of the seedling is involved, the root shrivels, and the stalk and leaves finally die, while a third form, which has been known to cause serious loss, especially in the seed beds, is due to species of millipedes.

Ginseng is also reported to be subject to attacks of nematodes, which produce their characteristic effects upon the roots. Where the ground is open and subject to heavy freezing, there is not believed to be much danger from this pest; but where it receives mulching or protection from the cold, the freezing will not destroy the nematodes.

A black rot of ginseng due to a species of Alternaria is described, as well as a soft rot which has not yet been definitely determined as due to any specific cause. In the soft-rot disease the roots decay very rapidly, becoming sticky and ill-smelling. A species of Fusarium, as well as bacteria, are usually present in great abundance, and the foliage is attacked by a species of Botrytis, but as yet the definite cause of

the root rot has not been determined. A leaf spot caused by Alternaria is described at some length, and the injury caused by snails, scale insects, and stem borers is noted.

Investigations on the prevention of Botrytis cinerea, P. DE LA BATHIE (*Rev. Vit., 21 (1904), No. 540, pp. 433–438*).—An account is given of a series of experiments for the prevention of the gray rot of grapes due to *Botrytis cinerea*. A vineyard was divided into 3 zones, the vines of one of which were sprayed, the second sprayed and the diseased leaves removed, while in the third the vines had all the diseased leaves removed but were not sprayed. The fungicides used were a trade preparation known as "Matarotine," a mixture of alum and lime, a solution of permanganate of potash, a simple solution of alum, powdered gypsum, and a mixture of lime and aluminum sulphate.

The disease appeared at 2 distinct epochs, the first between July 18 and 31 and the second at a considerable interval. None of the treatments were efficient in preventing its attack. The removing of the diseased leaves combined with the application of the fungicides appeared to slightly reduce the disease, but only to a very limited extent. In the investigations reported upon a decided difference was noted in the resistance of different varieties toward the fungus, and investigations will be continued along the line of disease resistance.

Investigations of the brunissure of grapes, L. RAVAZ (*Prog. Agr. et Vit. (Ed. L'Est), 25 (1904), No. 19, pp. 568, 569*).—The results of some experiments conducted in the vineyard of the School of Agriculture of Montpellier for the control of brunissure are given. In these experiments the author pruned the stock in various ways, cutting back some very short, others as ordinarily pruned, while a third lot were allowed to carry a great number of canes with 4 or more buds.

At fruiting time the stock bearing the least number of grapes fared best. The author maintains that brunissure is not due to any fungus, but is a result of overbearing, and the intensity of the disease is in proportion to the production and total growth of the stock. If this hypothesis is true, then diminishing the production of grapes and stimulating the vegetative growth by the use of fertilizers rich in potash will prevent the disease. It is said that in his study the author is convinced that brunissure is an infection of young vines and its recent distribution and occurrence is to be attributed to the restoration of vineyards which have been destroyed by the Phylloxera.

Grape anthracnose, P. PACOTTET (*Rev. Vit., 21 (1904), No. 525, pp. 5–8, pl. 1*).—An account is given of the grape anthracnose due to *Sphaceloma ampelinum*. This disease is said to be widely distributed and at times very serious in its injury to the grape crop. For its prevention the author recommends a winter treatment of a strong solution of iron sulphate to which is added sulphuric acid. This may be followed during the growing season by applications of other fungicides as the conditions of the season require.

Oïdium and Uncinula spiralis, J. M. GUILLON and G. GOUIRAND (*Rev. Vit., 20 (1903), No. 523, pp. 725–727*).—A review is given of the occurrence of the powdery mildew of the grape and the relation between the conidial stage, *Oïdium* or *Erysiphe tuckeri*, and the perithecial stage, *Uncinula spiralis*, pointed out.

Cultures of the black-rot fungus, P. VIALA and P. PACOTTET (*Rev. Vit., 21 (1904), No. 529, pp. 117–122, figs. 3*).—An account is given of the successful cultivation on artificial media of the black-rot fungus *Guignardia bidwellii*.

Cultures of this fungus were obtained by using portions of mycelium separated from affected grapes, the mycelium and portions of the pulp being transferred to the culture medium. After 8 to 10 days it was found that the mycelium had grown extensively and in 15 days the fungus was in the fruiting stage. The effect of acids and sugar of different kinds on the growth of the fungus is shown.

Simultaneous treatment for powdery and downy mildew, D. DONON (*Jour.

Agr. Prat., n. ser., 7 (1904), No. 21, pp. 678, 679).—The author recommends the addition of sublimed sulphur to Bordeaux mixture when spraying grapevines, the addition of the sulphur being for the purpose of preventing the occurrence of the powdery mildew.

It is recommended that to the ordinary solution of copper sulphate should be added 2.5 kg. of sublimed sulphur thoroughly mixed with the amount of lime necessary to make 100 liters of Bordeaux mixture. Instead of this preparation a second is suggested, the addition of miscible sulphur, which consists of sublimed sulphur, 70 per cent; carbonate of soda, 20 per cent, and powdered resin, 10 per cent. This can be readily added to a copper solution at the rate of 2.5 kg. per 100 liters.

The use of verdigris for the control of downy mildew, E. Chuard and F. Porchet (*Chron. Agr. Canton Vaud, 17 (1904), No. 12, pp. 351, 352*).—In reply to numerous inquiries regarding the use of neutral acetate of copper at the viticultural station, the authors give a brief account of the use of this fungicide, comparing it with Bordeaux mixture.

The verdigris solution used was a 1 per cent solution, and 2 equal plats of grapevines received a spraying of the neutral verdigris and Bordeaux mixture on the same day. Ten days later, heavy rains having fallen, an examination was made of each treated plat, and it was found that the verdigris solution was more adherent than the Bordeaux mixture. One objection to the use of this solution is that there are no evident traces of its having been applied to the vines. In order to correct this, numerous attempts have been made to add neutral substances, such as white clay, kaolin, and carbonate of magnesia, to show where the fungicide had been sprayed. As yet none of these have proved entirely satisfactory.

Simultaneous treatment for preventing attacks of the grape-fruit worm and the downy mildew, G. Martin (*Rev. Vit., 21 (1904), Nos. 531, pp. 177–180; 532, pp. 222–225; 533, pp. 241–243*).—The use of a combined fungicide and insecticide for preventing attacks of the grape-fruit worm and the downy mildew is recommended. Directions are given for the preparation and application of a mixture which consists of resin 15 kg., caustic soda 2 kg., verdigris 1 kg., ammonia 10 liters, and water 100 liters. This solution has been successfully used by the author in spraying nearly 800,000 vines.

Grape phthiriosis, L. Mangin and P. Viala (*Rev. Vit., 21 (1904), Nos. 532, pp. 205–210; 533, pp. 237–241, figs. 8*).—In continuation of the previous report on this disease of grapes due to symbiosis between *Dactylopius vitis* and *Bornetina corium* (E. S. R., 15, p. 165), the authors add a number of facts to the biology of the insect and its symbiotic fungus.

A note on the gray rot of grapes in Algeria, L. Trabut (*Rev. Vit., 21 (1904), No. 544, pp. 563, 564, fig. 1*).—Attention is called to the fructification of *Botrytis cinerea* on various portions of grapevines and particularly to the lesions caused by the fungus on the petioles and adjacent portions of the vines.

The chlorosis of fruit trees and its treatment, J. Lochot (*Rev. Hort. [Paris], 76 (1904), No. 10, pp. 236, 237*).—The use of sulphate of iron for the prevention of chlorosis is commented upon, this chemical being used not only to water about the roots, but also as a spray to the leaves. When used in too strong a solution, it frequently injures the foliage to a very considerable extent.

The author describes a treatment which consists of thoroughly spraying the trees late in autumn with a concentrated solution of copper sulphate. This treatment has been successfully applied in a number of instances, and it is further recommended for the horizontal branches of the trees that, cutting through the bark at intervals of about a foot, will aid in admitting the iron salt to the tree and obtain more rapid results. Another method mentioned is that of boring small holes into the affected trees and putting from 4 to 12 gm. of sulphate of iron into the tree trunk.

Investigations of rusts, M. A. Carleton (*U. S. Dept. Agr., Bureau of Plant Industry Bul. 63, pp. 32, pls. 2*).—An account is given of experiments and observations on various rusts in continuation of the work reported in Division of Vegetable Physiology and Pathology Bulletin 16 (E. S. R., 11, p. 942). Notes are given relative to the rusts of a number of plants of economic importance, while others serve to elucidate some disputed points in the life history of the fungi. The studies include those of Euphorbia rust, sunflower rust, crown rust of oats, black stem rust of redtop, willow and cottonwood rusts, etc.

The author concludes from his investigations that the rust occurring on the common sunflower is identical with that on *Helianthus mollis* and *H. petiolaris*, and is probably distinct from that occurring on *H. tuberosus*. Investigations on the crown rust of oats serve to show the connection of the æcidial form on Rhamnus and the identity of the crown rust of oats with the forms known to occur on *Phalaris caroliniana* and *Arrhenatherum elatius*.

Brief accounts are given of attempts by the author to segregate to their host plants a number of species of rusts, and notes are given on the winter resistance, emergency adaptations, and perennial species of a number of rusts.

Diseases of fruits, W. T. Macoun (*Canada Expt. Farms Rpts. 1903, pp. 106, 107*).—Brief notes are given on the apple-spot fungus, the ripe rot or brown rot of peaches and plums, peach-leaf curl, and the black rot of grapes. These diseases are briefly described and suggestions given for their prevention.

Spraying, W. T. Macoun (*Canada Expt. Farms Rpts. 1903, pp. 104–106*).—Notes are given on experiments in spraying apple trees for the prevention of fungus and insect attacks. The formula recommended consists of copper sulphate 4 lbs., unslaked lime 4 lbs., Paris green 4 oz., and water 40 gal. Experiments are also reported of the use of a dust spray similar to that described in Missouri Station Bulletin 60 (E. S. R., 15, p. 166).

The experiments conducted by the author seemed to indicate that the powdered form was less satisfactory than where the usual liquid Bordeaux mixture was employed. It is believed, however, for orchards on rough ground or steep hillsides where liquids are difficult of application that the dust spray will perhaps prove of value.

The use of sulphur fungicides, E. Total (*Rev. Vit., 21 (1904), No. 542, pp. 494–497*).—The author recommends the addition of sublimed sulphur at the rate of 2.5 to 3 kg. per 100 liters of Bordeaux mixture for spraying to protect vines against black rot, gray rot, powdery mildew, etc.

ENTOMOLOGY.

Report of the entomologist, J. Fletcher (*Canada Expt. Farms Rpts. 1903, pp. 163–211, figs. 23*).—One of the most important insect pests of cereals during the year was the grain aphis. Notes are given on the prevalence of this pest in various parts of the Dominion of Canada and also on the ravages of wheat-stem saw fly, Hessian fly, locusts, and other insects of cereals.

The Criddle mixture was used successfully in destroying locusts, but the fungus disease was without effect. Considerable injury is reported from the attacks of clover-seed midge and hop aphis. The best insecticide for the latter pest consists of 4 to 5 lbs. of soft soap and 6 to 8 lbs. quassia chips per 100 gal. water. Notes are presented on a large number of insect pests of cabbage, sugar beets, and other garden vegetables and fruits. The more important fruit pests during the year were oyster-shell bark-louse, scurfy bark-louse, bud moth, apple aphis, pear psylla, pear-leaf blister-mite, and San José scale. As a result of a long series of experiments it is recommended that salt be omitted from the lime sulphur-salt mixture in combating this insect. It is also

possible to prepare the mixture without boiling. A brief account is presented of some of the more important insects of shade trees.

A report is given by J. Fixter on the apiary. Good results were had in protecting bee colonies in winter by surrounding the hives with layers of brown building paper and oil paper. The colonies of bees kept over open pails of water showed no bad effects from exposure to moisture. Good results were had in feeding bees on maple sugar, honey, and a mixture of candied honey and sugar. In treating bee colonies for foul brood, excellent results were had by the McEvoy method.

Special report of assistant superintendent of entomology to the board of commissioners, R. C. L. PERKINS (*Hawaiian Forester and Agr., 1 (1904), No. 4, pp. 75–84*).—The economic entomologists of Hawaii are chiefly occupied in preventing the importation of injurious insects and in combating those which are already present. Brief notes are presented on the organization and work of the division of entomology under the Hawaiian Board of Commissioners. Notes are also given on diseases of sugar cane as related to the leaf hopper and on the damage done to sugar cane by fungus diseases.

Proceedings of the Entomological Society of Washington (*Proc. Ent. Soc. Washington, 6 (1904), No. 3, pp. 127–192, figs. 9*).—In this number of the proceedings the following subjects are discussed: Two new species of caddice flies; Notes on the structure of the thorax and maxillæ in insects, by Nathan Banks; On the species of Sphenophorus hitherto considered as simplex; On the species of Sphenophorus hitherto considered as placidus, by F. H. Chittenden; New Diptera from India and Australia; New North American Diptera, by D. W. Coquillet; Two new forms of Œneis; Notes on synonymy and larvæ of Pyralidæ, by H. G. Dyer; Diverse mosquito larvæ that produce similar adults, by H. G. Dyar and F. Knab; and Notes on North American Aradidæ, with descriptions of two new species, by O. Heidemann.

A critical study of the mutation and selection theories in relation to Lepidoptera, C. SCHRÖDER (*Allg. Ztschr. Ent., 9 (1904), No. 15–16, pp. 281–297, figs. 10*).—A critical review is presented of the literature relating to this subject in the study of Lepidoptera. The author maintains that mimicry and similar phenomena are easily explained on the basis of the theory of natural selection and can not be held to militate in any way against this theory.

Ants which live in symbiosis with plants in the Amazon region and in Peru, A. FOREL (*Zool. Jahrb., Abt. Syst., 20 (1904), No. 6, pp. 677–707*).—A number of ants were collected by E. Ule along the Amazon and in Peru, and a careful study of these insects disclosed the fact that they lived in symbiotic relation with various species of plants. The different species are described by the author and notes are given on their peculiar habits of life. The genera chiefly represented are Azteca, Camponotus, etc.

The biology of insects, C. KOPP (*Jahreshef. Ver. Vaterl. Naturk. Württemberg, 60 (1904), pp. 344–350*).—Notes are presented on the habits, life history, and especially on the nest construction of *Ammophila sabulosa*, *Osmia bicornis*, and other species of insects and spiders.

Agricultural pests and diseases in the Province of Bologna, D. CAVAZZA and L. ZERBINI (*Ann. Uffic. Prov. Agr., Bologna, 10 (1902–3), pp. 224–243, figs. 3*).—Brief notes are given on red spider, mites on grape vines, woolly aphis, brown-tail moth, parasitic fungi, and field mice. Especial attention is devoted to a discussion of the methods of destroying the latter. The methods discussed are drowning by submerging, poisoning, and use of infectious diseases. On ground situated favorably for submersion this method is very cheap and efficacious. In general, however, the best results are obtained from the use of arsenical and other poisons such as strychnine, nux vomica, phosphorus, potassium cyanid, etc.

The authors tested the method which has lately given such good results in France and which consists in the use of cultures of infectious diseases. The results obtained

are fairly satisfactory. A copy is given of a set of regulations adopted by the provincial council for the destruction of field mice.

A preliminary list of the insects of economic importance recorded from the Hawaiian Islands, J. G. KIRKALDY (*Hawaiian Forester and Agr., 1 (1904), Nos. 6, pp. 152–159; 7, pp. 183–189; 8, pp. 205–210*).—This list is prepared for the purpose of furnishing information regarding the number and distribution of injurious insects in the Hawaiian Islands. Lists are presented of Hemiptera, Orthoptera, Lepidoptera, and Hymenoptera of the islands with bibliographical references.

Annual report of the inspector of cocoanut trees, 1902, L. C. BROWN (*Agr. Bul. Straits and Federated Malay States, 2 (1903), No. 5, pp. 161–163*).—The author made a study of a cocoanut grove in the Federated Malay States and found that many trees were cut down and left to lie in a half-rotten condition on the ground. Such trunks serve as breeding places for borers and other injurious insects. With proper precautions and the application of clean cultural methods the losses from insect pests can be gradually reduced.

Report of the government entomologist, E. E. GREEN (*Roy. Bot. Gard. Ceylon Administr. Rpts. 1903, pt. 4, pp. 10–18*).—Notes are given on the habits and life history of a number of injurious insects, in particular the more important pests of tea, coffee, cacao, rubber, timber, etc.

Further notes on pests attacking cotton in the West Indies, H. A. BALLOU (*West Indian Bul. 4 (1904), No. 4, pp. 326–354*).—Detailed notes are given on the habits, life history, natural enemies, and means of combating the cotton worm, cotton stainer, red maggot, *Eriophyes gossypii*, and various fungus diseases of cotton. As a result of the study of insect and fungus diseases of cotton, recommendations are made for the culture of cotton according to methods which will assist in preventing the damage from these pests.

The sting in the apple.—The work of the plum curculio in the apple, J. M. STEDMAN (*Missouri Sta. Bul. 64, pp. 24, figs. 10*).—During the summer of 1904 a serious attack of plum curculio on apples was observed throughout the State of Missouri. Nearly all of the injuries were due to the plum curculio, while a small percentage of damage was caused by the apple curculio.

The plum curculio attacked the apples about the middle of May and became most numerous in June. The females make punctures for the purpose of obtaining food and for the purpose of oviposition. About 5 times as many feeding punctures were observed as egg punctures. When the adult beetles appear later in the season they have the habit of eating the apple pulp, making holes of considerable size. A number of punctures may be made in the single fruit and these punctures may serve as points of entrance for fungus diseases. The plum curculio does not readily breed in the apples. Apparently not more than 15 per cent of the eggs which are deposited ever hatch and not more than 2 per cent develop to the adult condition.

Detailed notes are given on the life history and habits of this pest especially in connection with apple orchards. According to the author's experience, the pests may be successfully controlled by spraying with arsenate of lead once or twice before the blossoms open and 3 or 4 times after the blossoms have fallen at intervals of 10 days. All windfalls should be destroyed at intervals of about 7 days and the orchard should be plowed and receive shallow cultivation in the middle of July and again in August.

Observations on the habits of the asparagus fly, P. LESNE (*Rev. Hort. [Paris], 76 (1904), No. 14, pp. 332, 333, fig. 1*).—The asparagus fly (*Platyparea pœciloptera*) has long been known as an enemy of asparagus. The author made a study of the habits and life history of this pest. A great variation was observed in the time of the development of the larvæ from the egg stage. The deposition of eggs in the tissues about the tip of growing stems of asparagus appears to indicate the possibility

of a second brood of the insect. This point will be more carefully studied by the author.

The cabbage-root fly (*Jour. Bd. Agr.* [*London*], *11* (*1904*), *No. 6*, *pp. 352–355*).—Notes are presented on the habits and life history of *Phorbia brassicæ*. In preventing damage from this insect, the use of tarred paper or cards around the cabbage plants, sprinkling sand saturated with kerosene around the plants, and destruction of badly infested cabbages is recommended.

Report on the life history and habits of the imported brown-tail moth, C. H. FERNALD and A. H. KIRKLAND (*Boston: State Bd. Agr.*, *1903*, *pp. 73*, *pls. 14*).—A historical account is presented of the discovery of this insect in America, its gradual spread, and present distribution, together with notes on the irritation caused by the nettling hairs of the caterpillars and the injury to fruit and shade trees.

The brown-tail moth was first noted in considerable numbers in this country in 1897 and has since become distributed over a considerable portion of Massachusetts. Copies are presented of letters from various individuals who have suffered injuries from the nettling hairs of the caterpillars. The life history of the insect is described in considerable detail.

A number of natural enemies of the brown-tail moth are known, including predaceous and parasitic insects as well as birds. Reliance must be placed, however, in artificial remedies, particularly web destruction during the period from October to April, when these insects are massed together in their winter webs. These webs may be very readily detected and destroyed with the caterpillars. Other methods recommended consist in application of arsenical poisons and banding trees with sticky substances.

The true gall gnats of the pear, V. FERRAUT (*Allg. Ztschr. Ent.*, *9* (*1904*), *No. 15–16*, *pp. 298–304*).—The author discusses the synonomy of *Cecidomyia nigra*, *Sciara pyri*, *S. schmidbergeri*, and *Diplosis pirivora*. The habits and life history of the last-named species are briefly described. In combating this pest the author recommends that infested pear trees be vigorously shaken daily and that all pears which fall be at once destroyed.

A sugar-cane leaf hopper in Hawaii, D. L. VAN DINE (*Hawaii Sta. Bul. 5*, *pp. 29*, *figs. 8*).—The leaf hopper which has caused most damage to sugar cane in Hawaii has been determined as *Perkinsiella saccharicida*. This insect and the cane borer are considered as the most destructive pests of sugar cane.

Detailed notes are given on the life history of the leaf hopper and on the appearance of the insect in its different stages. The adult females injure the leaf during oviposition and the young leaf hoppers damage the plants in feeding. The attack of this pest is also followed by a fungus growth belonging to the genus Sphæronema. The first symptom of the attack of these insects is a formation of reddish spots along the midrib of the leaves.

The natural enemies of the leaf hopper can not be depended upon and the control of the pests must be brought about by artificial means. Experiments were made in testing the value of kerosene emulsion, lime dust, stripping the lower infested leaves, and collecting the leaf hoppers by nets.

The results obtained by the use of sprays, dust insecticides, and nets were not very satisfactory. In the level fields, however, before the cane has attained a height of 3 or 4 ft. it is believed that a spray of kerosene emulsion may be effectively delivered. In cases where the black fungus is abundant on the cane it is recommended that the plants be dusted with a mixture of lime and copper sulphate. In preventing the attacks of leaf hoppers the author recommends clean methods of cultivation combined with proper cultivation and the use of fertilizers.

Means for preventing damage caused by weevils and moths to stored grain, P. GENNADIUS (*Cyprus Jour.*, *1* (*1904*), *No. 5*, *pp. 5–7*).—It has been found

that in Cyprus cereals thrashed and placed in a clean storeroom early in the season are not attacked by granary insects. Some of the farmers in Cyprus scatter bulbs of squill over the piles of grain in order to prevent the attack of these insects. A number of other plants such as species of Origanum, *Inula viscosa*, etc., are occasionally used for the same purpose.

The processionary moth of the pine tree, P. GENNADIUS (*Cyprus Jour., 1 (1904), No. 4, pp. 9, 10*).—*Cnethocampa pityocampa* is common along the Mediterranean and occurs in such numbers as to strip whole groves of pine trees of their foliage. The habits and life history of this species are briefly described. The caterpillars are furnished with nettling hairs. In combating the pest the author recommends that branches bearing nests of the caterpillars be cut off and burned.

The Congo floor maggot, J. E. DUTTON, J. L. TODD, and C. CHRISTY (*British Med. Jour., 1904, No. 2281, pp. 664–666, figs. 2*).—A description is given of floor maggots as found in the Lower Congo region. These pests are reported as attacking man for the purpose of obtaining blood. Experiments with maggots show that they could live also on rats and guinea pigs. Further experiments will be made to determine whether these larvæ are capable of transmitting any form of trypanosomiasis. The larvæ were identified as belonging to the species *Auchmeromyia luteola*.

What Government experts are doing to destroy the boll weevil, C. A. WILLIAMS (*World To-day, 7 (1904), No. 4, pp. 1307–1313, figs. 11*).—The author briefly discusses the economic importance of cotton and the great injury which this industry has suffered from the ravages of the boll weevil. Attention is called to the work outlined by this Department for the control of the boll weevil and brief hints are given as to future work along this line.

The boll weevil in Texas (*U. S. Dept. Com. and Labor, Bureau of the Census Bul. 10, pp. 15–17, fig. 1*).—The history of this pest is briefly outlined with notes on its present distribution in Texas and the amount of damage caused by it.

Tortrix pilleriana and Haltica ampelophaga, J. PERRAUD (*Rev. Agr., Vit. et Hort., 1 (1903), Nos. 1, pp. 7–10; 2, pp. 25–35; 5, pp. 103–110; 8, pp. 169–172; 11, pp. 254–257; 12, pp. 265–270; 2 (1904), Nos. 14, pp. 36, 37; 15, pp. 52–54*).—The habits and life history of these insect pests of the grape vine are discussed in great detail and the various methods used for their destruction are described.

These methods consist in spraying with a large variety of insecticides, boiling water, sulphur fumes, etc. The eggs may be readily found and destroyed and various contact insecticides are useful in the destruction of the larva. For this purpose particular mention is made of tobacco juice, black soap, kerosene emulsion, and other similar insecticides. The moths may be trapped by lanterns and the use of sugar.

A number of insects prey upon both *T. pilleriana* and *H. ampelophaga*, and these species are briefly described by the author with notes on their distribution and relative importance. One of the most successful insecticide operations in connection with the caterpillars of *T. pilleriana* is the use of boiling water as a spray during the winter season.

The prey of Methoca ichneumonides, G. ADLERZ (*Ark. Zool., 1 (1904), No. 3, pp. 255–258*).—This species belongs to the family Mutillidæ and its habits were studied in the central part of Sweden. The author found that this species could attack and destroy the larvæ of tiger beetles.

Combating the olive fly, TRABUT (*Bul. Agr. Algérie et Tunisie, 10 (1904), No. 10, p. 227*).—The olive fly was observed to be easily attracted by sweetened fluids. A successful attempt was therefore made to destroy these insects by preparing a mixture of molasses, honey, glycerin, water, and arsenate of soda.

Anobium paniceum in wheat, A. LEGAULT (*Bul. Agr. Algérie et Tunisie, 10 (1904), No. 11, p. 233, fig. 1*).—Brief notes are given on the appearance and habits of this

insect. It may be destroyed by subjecting infested wheat to a temperature of 60° C. for an hour or by fumigation with carbon bisulphid.

The Hessian fly, F. DESPREZ (*Jour. Agr. Prat., n. ser., 8 (1904), No. 36, pp. 319, 320*).—The injurious attacks of this insect are briefly noted, and an account is given of its distribution. The usual remedies have been tried in controlling this pest. During the coming year it is proposed to make a further test for the purpose of studying the resistance of various varieties of wheat toward the Hessian fly.

Pebrine and related micro-sporidia, A. LUTZ and A. SPLENDORE (*Centbl. Bakt. u. Par., 1. Abt., Orig., 36 (1904), No. 5, pp. 645–650, pls. 2, fig. 1*).—Species of Nosema and related organisms were found by the authors as parasitic in a considerable variety of insects. These organisms are described and notes are given on their life history, distribution, and economic importance.

The life history and treatment of a common palm scale, H. E. HODGKISS (*Reprinted from Massachusetts Agr. Col. Rpt. 1904, pp. 12, pls. 2*).—The life history and appearance of *Chrysomphalus dictyospermi* are described, with notes on the systematic position of this insect, its food plants, economic importance, and methods of combating it.

The author conducted a number of experiments in fumigating infested greenhouses with hydrocyanic-acid gas for the purpose of determining the proper quantity of chemicals to be used. As a result of these experiments, it is recommended that 0.075 gram, or a maximum of 0.1 gram of cyanid of potash, be used per cubic foot of space for a period varying from 20 to 40 minutes, according to the amount of chemical used. Palms should be free from moisture, fumigated only after dark, and greenhouses should be properly ventilated after fumigation.

The pineapple scale, D. L. VAN DINE (*Hawaiian Forester and Agr., 1 (1904), No. 5, pp. 111–114*).—Notes are given on the distribution and occurrence of *Diaspis bromeliæ*. The natural enemies of this insect are considered to be of no importance to the planter. For combating the pest the author recommends the use of kerosene emulsion or resin wash.

The mussel scale (*Bd. Agr. and Fisheries [London], Leaflet 107, pp. 4, figs. 2*).—The mussel scale or oyster-shell bark-louse is described and insecticide applications are recommended for its destruction. Notes are given on the preparation and use of hydrocyanic-acid gas.

Plant lice (*Bd. Agr. and Fisheries [London], Leaflet 104, pp. 3*).—A brief account of the life history, occurrence, natural enemies, and artificial remedies of these pests.

A Castilloa borer, H. N. RIDLEY (*Agr. Bul. Straits and Federated Malay States, 2 (1903), No. 10, p. 322*).—Young trees of the species *Castilloa elastica* are reported as being greatly injured by a borer identified as *Epepseotes luscus*. The beetle is described and notes are given on its habits. It flies by night. The grubs may be destroyed in the trunks of the tree by means of curved wires and insecticides.

Notes on two insects, W. CARTWRIGHT (*Jour. Khediv. Agr. Soc. and School Agr., 6 (1904), No. 1, pp. 17–19*).—The larvæ of *Trypeta capitata* were found injuring oranges by feeding on the pulp of the fruit. In controlling this pest it is recommended that fallen fruit be at once collected and destroyed and that the soil under infested trees be treated with ferrous sulphate. The author observed considerable injury to barley from the attacks of *Hylemyia coarctata*. Stimulating fertilizers and rolling of the ground are recommended in controlling the pest.

The ichneumons of Great Britain, C. MORLEY (*Plymouth: James H. Keys, 1903, pp. L+315, pl. 1, figs. 19*).—It was felt that this group had not been considered in a monographic form in Great Britain, and the present volume was therefore prepared to supply the demand for such information. The various species are described and notes are given on their habits, life history, and means of distribution. A glossary of technical terms is added to the volume, together with an index of synonyms and a list of the hosts on which the ichneumons live.

[Monthly bulletin of the Division of Zoology], H. A. SURFACE (*Pennsylvania State Dept. Agr. Mo. Bul. Div. Zool., 2 (1904), No. 4, pp. 99–128, pls. 2*).—Practical remedies are suggested for insect pests which are most prevalent in August, and notes are given on mosquito bites, bee stings, insects as carriers of disease, shade-tree pests, bird preservation, etc.

[Monthly bulletin of the Division of Zoology], H. A. SURFACE (*Pennsylvania State Dept. Agr. Mo. Bul. Div. Zool., 2 (1904), No. 5, pp. 131–160, figs. 5*).—Brief notes are given on practical measures for controlling insects and fungus diseases of various crops, together with short accounts of spraying apparatus, inspection of nurseries, rearing insects, etc.

Nocturnal moths and lantern traps, J. A. SOBRAL (*Bol. Agr. São Paulo, 5. ser., 1904, No. 6, pp. 269–271*).—As a result of various tests with lantern traps for the purpose of catching injurious night-flying moths, the author recommends that such lanterns be placed not farther apart than 25 meters.

The use of hydrocyanic acid as an insecticide, A. RICHON (*Rev. Hort. [Paris], 76 (1904), No. 15, pp. 358–360*).—Detailed notes are given on the effect of this gas upon various insects and plants. Thrips and various species of plant lice, red spider, and various caterpillars were destroyed by doses varying from 1 to 3 gm. of cyanid of potash per cubic meter of space applied for periods of from 20 to 40 minutes. Some delicate plants were very much injured by the use of 3 gm. of cyanid of potash per cubic meter of space. With the observation of proper precautions, however, this remedy is considered safe as well as very effective.

Disinfection of greenhouses by hydrocyanic acid, COSTANTIN (*Rev. Hort. [Paris], 76 (1904), No. 8, pp. 191, 192*).—Formulas are given showing the required amounts of cyanid of potassium, sulphuric acid, and water in the development of hydrocyanic acid of the proper strength to destroy injurious insects without injuring ordinary greenhouse plants.

The author finds that the amount of cyanid of potassium may vary from 2½ to 3½ gm. per cubic meter of space, according to the delicacy of the plants to be fumigated. It was found that most plants are unharmed by these strengths if kept dry just before and during the process of fumigation. Plant lice, thrips, red spider, mealy bugs, and various species of scale insects were successfully destroyed by one fumigation. The efficacy of fumigation with hydrocyanic acid was considerably superior to the use of nicotine or fumigation with tobacco.

Report of the inspector of fumigation appliances, 1903, P. W. HODGETTS (*Toronto: Ontario Dept. Agr., 1904, pp. 12*).—A brief outline is presented of the conditions observed in nurseries and orchards in various parts of Canada with reference to infestation with San José scale.

Infested nurseries are inspected and fumigated in the spring and fall. The formula for the development of hydrocyanic acid includes 1 ounce cyanid, 1 fluid ounce sulphuric acid, and 3 fluid ounces water per 100 cubic feet of space. A copy is given of an act passed for the prevention of the spread of San José scale, together with regulations based on this act for the fumigation of nursery stock.

Preparation and use of kerosene emulsion, F. SHERMAN, Jr. (*North Carolina Dept. Agr., Ent. Circ. 10, pp. 6*).—Brief notes on the formulas for the preparation of kerosene emulsion, with an account of the proper methods of preparing, diluting, and applying this insecticide.

Fumigation of nursery stock. Inspection laws of other States, W. NEWELL (*Georgia State Bd. Ent. Bul. 11, pp. 23, figs. 7*).—The regulations of the Georgia State Board of Entomology regarding the fumigation of nursery stock are briefly outlined, with notes on fumigation, apparatus, chemicals, construction of fumigating houses, etc. Formulæ are given for computing the amount of chemicals required for given spaces. The requirements of various States with regard to fumigation are also discussed.

Experiments to test the value of Bug Death as compared with Paris green and Bordeaux and Paris green on potatoes, R. ROBERTSON (*Canada Expt. Farms Rpts. 1903, pp. 296, 297*).—The experiments reported with these insecticides indicate that many of the treatments are effective in destroying potato beetles, but that Paris green is exceedingly cheap as compared with treatment by means of Bug Death.

Chemistry of insecticides and fungicides, F. T. SHUTT (*Canada Expt. Farms Rpts. 1903, pp. 152–155*).—Analyses are presented of Kno Bug, Bug Finish, and formalin. Insecticidal properties of Kno Bug and Bug Finish were found to be fairly satisfactory, but the claims made concerning the fertilizing action of these preparations are quite unfounded. The products also cost much more than homemade insecticides. According to analyses made by the author the amount of formaldehyde by weight in commercial formalin varies from 36 to 37 per cent. An analysis was made of Owens' compound for the protection of trees against insect and fungus ravages. This preparation was found to consist largely of sulphur to which from 5 to 10 per cent of charcoal had been added.

Spraying calender, L. R. TAFT and C. D. SMITH (*Michigan Sta. Spec. Bul. 26, folio*).—Recommendations are made in a tabular form of insecticides and fungicides to be applied in controlling the more important insect and fungus diseases of fruits and garden vegetables. Formulas are also presented for the preparation of these sprays.

Supplementary notes on the tsetse flies, E. E. AUSTEN (*British Med. Jour., 1904, No. 2281, pp. 658–662, fig. 1*).—Descriptive, biological, and economic notes are presented on several species of the genus Glossina. This article is intended to contain information supplementary to the author's monograph of tsetse flies. The habits of these insects in their various stages are described in considerable detail, especially in relation to their agency in the transmission of diseases. An analytical table is presented for the determination of the species.

Malaria and mosquitoes, G. MCCARTHY (*Bul. North Carolina State Bd. Agr., 25 (1904), No. 6, pp. 66–76, figs. 10*).—The life cycle of the malarial parasite is briefly outlined and notes are given on the habits and life history of a number of mosquitoes which commonly occur in North Carolina, with especial reference to the species concerned in transmitting malaria. Approved methods of destroying mosquitoes are recommended.

The honeybee, T. W. COWAN (*London: Houlston & Sons, 1904, 2. ed., pp. XII+220, pl. 1, figs. 73*).—This volume has been revised so as to include some of the more recent work on the habits and biology of the honeybee. The volume is occupied chiefly with a scientific and entomological discussion of this insect rather than with its economic importance. Especial chapters are devoted to the gross and microscopical anatomy of various organs of bees, and an account is presented of drones, queens, parthenogenesis, metamorphosis, and comb construction.

Bees, S. A. BEDFORD (*Canada Expt. Farms Rpts. 1903, p. 338*).—Some losses in bees are reported as a result of inadequate stores during the winter. The best success was had in shipping bees in the Langstroth hives. Sweet clover is considered as a very good and productive bee plant.

Chemistry of bee keeping, F. T. SHUTT (*Canada Expt. Farms Rpts. 1903, pp. 155–158*).—Experiments carried on during the year under report showed that extracted honey exposed to an atmosphere saturated with moisture soon exhibited signs of deterioration, becoming thin and rapidly fermenting. Honey in the comb was similarly affected, but resisted the effects of moisture for a much longer time. It is recommended on the basis of these experiments that honey be stored in a warm, dry atmosphere. Notes are given on the analysis of beeswax, some of which was found to be greatly adulterated with paraffin.

Studies on the poison of bees, C. PHISALIX (*Compt. Rend. Acad. Sci. Paris, 139*

(*1904*), *No. 4*, *pp. 326–329*).—As the result of a prolonged chemical and biological study of bee poison the author concludes that this poison contains 3 distinct active principles, viz., a body which causes an elevation of temperature and which is destroyed at a temperature of 100° C., a toxin which produces muscular convulsions and which does not resist prolonged boiling, and a toxin which exercises a stupefying effect and which is not completely destroyed until a temperature of 150° C. is reached.

The existence of 2 toxins exhibiting antagonistic action is considered a new discovery, and further study will be made for the purpose of determining whether this fact can be made use of in a practical manner.

Sericulture (*Japan in the Beginning of the 20th Century. Tokyo: Imperial Japanese Commission to the Louisiana Purchase Exposition, 1904, pp. 133–150*).—A historical statement is presented regarding government aid to this industry in former times, legislative measures for protecting sericulture, together with numerous data on the present condition of the industry in Japan. Statistics are presented on silkworm eggs, silk production, and reeling.

FOODS—NUTRITION.

Hygienic studies of flour and bread. XIII, Concerning flour, dough, and bread acids, DOMBROWSKY (*Arch. Hyg., 50* (*1904*), *No. 2*, *pp. 97–117*).—Various problems connected with the acidity of flour and bread were studied. Among the conclusions drawn were the following: The total acidity of the samples analyzed, calculated as lactic acid, ranged from 0.36 to 0.52 per cent of the dry matter with rye flour and 0.23 to 0.4 per cent with wheat flour. The acidity of dough is influenced aside from the time and temperature of the fermentation by the quantity of water used in mixing, that is, by the concentration of the dough.

By kneading the dough with water about 75 per cent of the total acid present may be readily removed. When bread is baked, 75 per cent of the acid of rye bread, 70 per cent of that of gray bread, and 58.5 per cent of that of wheat bread remains in the loaf. Other conclusions have to do with the kind and amount of the acids present and the relation of acidity to yeast and other micro-organisms.

Concerning wheat flour, H. STEIN (*Ztschr. Untersuch. Nahr. u. Genussmtl., 7* (*1904*), *No. 12*, *pp. 730–742*).—Different methods of separating gluten were compared, and the properties of gluten, methods of examining wheat flour, and the ferments of wheat were studied. According to the author, the addition of separated gluten to wheat flour might be profitably undertaken by bakers in place of blending. As regards the ferments of wheat, the author considers it probable that 2 are present, one of these apparently softening the gluten. The effect of wheat ferments on the character of the dough is briefly spoken of.

Examination of foods, condiments, and commercial products, M. BALLÓ (*Jahrb. Chem. Nahr. Untersuch. Budapest, 4* (*1901–3*), *pp. 123; abs. in Oesterr. Chem. Ztg., 7* (*1904*), *No. 12*, *p. 273*).—Data are given regarding the examination of a large number of foods and condiments.

The effect of alcohol, alcoholic drinks, tea, and coffee upon peptic digestion, N. J. PAWLOWSKI (*Russk. Vrach., 2* (*1903*), *p. 1475; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 8* (*1904*), *No. 2*, *pp. 156, 157*).—Tea and coffee, according to the author, diminished the digestive action of pepsin, an effect which must be attributed to some other constituent than caffein, since this was shown to have no effect on the digestion of protein by pepsin. Alcohol and alcoholic beverages also diminished the ferment action in the experiments reported. Conclusions were also drawn regarding the other subjects studied.

Concerning the chemical composition of coffee and coffee substitutes, F. DUCHÁČEK (*Ztschr. Untersuch. Nahr. u. Genussmtl., 8* (*1904*), *No. 2*, *pp. 139–146*).—The composition of the original material and extract matter of coffee and coffee sub-

stitutes was studied, the extract analyses including mineral constituents. The presence of caffein in coffee is, according to the author, the most important difference between true coffee and coffee substitutes. The differences in composition between the two classes of goods are spoken of.

A new method of preparing foods, S. Weisbein (*Berlin. Klin. Wchnschr., 40 (1903), pp. 587–590; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 7 (1904), No. 12, pp. 751, 752*).—A method of preparing a food product rich in gluten is described, which consists in mixing wheat flour with water and separating the gluten and salts from the bulk of the starch by means of a centrifugal machine. The portion containing gluten is dried and ground to a powder.

Some food products and their adulteration, H. G. Knight and R. B. Moudy (*Wyoming Sta. Bul. 62, pp. 55*).—Since the State pure-food law went into effect in September, 1903, a total of 425 samples of canned goods, butter, cheese, meats, condiments, beverages, etc., have been examined, of which 268 were found to be adulterated or misbranded. The adulteration was especially noticeable with canned goods and spices and condiments, 118 of the 126 samples of canned goods and 50 of the 98 samples of spices and condiments being adulterated or misbranded. Of the 5 samples of catsup examined all were adulterated or misbranded.

Concerning food preparations, A. Jolles (*Ztschr. Landw. Versuchsw. Oesterr., 7 (1904), No. 7, pp. 515–531*).—A number of commercial food products of recent introduction are described and their nutritive value discussed.

The household food supply, R. E. Turnbull (*Jour. British Dairy Farmers' Assoc., 17 (1902), pp. 29–39*).—The amount and value of food consumed in Great Britain is discussed with special reference to dairy products.

Naval dietary, J. Falconer-Hall (*British Med. Jour., 1904, No. 2275, pp. 272–274*).—The components of the British naval ration are enumerated, and food value, methods of preparation, issue of food components, and other topics are spoken of. According to the author's calculation, the ration furnishes per man per day 4.1 oz. protein, 2.1 oz. fat, and 20.2 oz. carbohydrates.

The chemical composition of different sorts of fish and the periodical variations which fish flesh undergoes, H. Lichtenfelt (*Arch. Physiol. [Pflüger], 103 (1904), No. 7–8, pp. 353–402, figs. 2*).—From a large amount of analytical data the author concludes that the muscular tissue of fish undergoes a periodical change in composition, which depends upon the age of the individual, the food eaten, and the spawning season.

The effect of hunger on the composition of the muscular tissue is to increase the percentage of water and correspondingly to diminish the dry matter. The greater the proportion of fat present, the larger the loss of fat in the muscles, especially as compared with the so-called lean varieties. Not only in the case of Rhine salmon, but also with other species of fish, hunger causes a diminution of proteid material. The amount of insoluble proteid is always diminished. The proportion of soluble proteid is sometimes increased, but may also be diminished.

This indicates that the different sorts of nitrogenous compounds have different physiological values. Muscular work in connection with hunger seems a combination especially suited to increase the amount of soluble proteids in fish flesh.

Examination of caviar, P. Buttenberg (*Ber. Hyg. Inst. Hamburg, 1900–1902, pp. 13–15; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 7 (1904), No. 4, pp. 233–235*).—Analytical data are reported.

A number of food products made from fish roe, E. Rimini (*Staz. Sper. Agr. Ital., 36 (1903), pp. 249–278*).—Analyses of caviar and similar products are reported.

The coloring matter and fat of egg yolk and the detection of egg yolk in foods, Laves (*Versamml. Deut. Naturf. u. Ärzte Cassel, 1903; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 7 (1904), No. 12, pp. 754, 755*).—The constituents of egg yolk

and the estimation of egg yolk in food products are spoken of, as well as the importance of convenient food products which contain egg yolk.

The hygienic value of preserving meat, HÜTTNER (*Deut. Vierteljschr. Öffentl. Gesundheitspfl., 35 (1903), pp. 501–553; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 7 (1904), No. 12, p. 749*).—From a discussion of the subject the author concluded that only fresh flesh of healthy animals should be preserved. Cold storage is regarded as the best method of preserving meat, Appert's method being very satisfactory for canning. The use of antiseptics, with the exception of common salt and smoke, in his opinion, should be forbidden. He points out that no sort of preserved meat should be used for a very long time and that preserved meat should be cooked. Other questions having to do with the subject of preserved meats are also considered.

Concerning unwholesome meat, H. VALLÉE (*Rev. Soc. Sci. Hyg. Aliment., 1 (1904), No. 1, pp. 26–34*).—The author discusses spoiled meat, the flesh of diseased animals, the unwholesomeness of such articles, regulations limiting their use, and related topics.

Borax as a preservative, E. ROST (*Borsäure als Konservierungsmittel. Berlin: Julius Springer, 1903, pp. 102+62*).—This publication contains a summary of investigations on the general question of borax and borax compounds as preservatives, including the author's own work, and is in part a critical discussion. A number of general conclusions are drawn, among others the following: Borax is a preservative of low disinfecting power and must be used in large quantities to insure protection; it may be deceptive in that it increases the weight of the food material and enables it to retain a greater amount of water than is the case when, for instance, it is preserved by pickling with salt or by smoking; it may produce harmful results immediately after consumption, and is regarded as cumulative. In addition to controversial matter, the supplement contains the text of a proposed law to prevent the addition of harmful products to meat and meat products.

Saltpeter in meat products, ORLOW (*Rev. Internat. Falsif., 16 (1903); abs. in Rev. Soc. Sci. Hyg. Aliment., 1 (1904), No. 1, pp. 91, 92*).—On the basis of experiments the author concluded that the red color of corned meat is due to nitrites rather than saltpeter. The presence of nitrites was also noted in fresh meat. Possible danger from the presence of nitrites in any considerable amount is pointed out.

Chemical and sanitary studies of sausage and chopped meat, A. J. SENNING (*Inaug. Diss., Univ. Dorpat., 1903, pp. 91; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 7 (1904), No. 12, p. 751*).—The author reported analyses of a considerable number of samples.

Concerning the constituents of asparagus, E. WINTERSTEIN and P. HUBER (*Ztschr. Untersuch. Nahr. u. Genussmtl., 7 (1904), No. 12, pp. 721–730*).—The authors studied the composition of the juice and dry matter of asparagus, especially the distribution of nitrogen in the juice.

Note on a new food plant from Central Africa, C. CHALOT (*Agr. Prat. Pays Chauds, 4 (1904), No. 19, pp. 104–106*).—A description of a tuber eaten in Africa called dazo (*Coleus dazo*), with an analysis by P. Ammann.

Concerning milk chocolate, O. LAXA (*Ztschr. Untersuch. Nahr. u. Genussmtl., 7 (1904), No. 8, pp. 471–477*).—On the basis of composition, the author discusses the identification of true milk chocolates and those not true to name.

Concerning the changes brought about in noodles by storage, H. JAECKLE (*Ztschr. Untersuch. Nahr. u. Genussmtl., 7 (1904), No. 9, pp. 513–528*).—Experimental data are reported and discussed with reference to judging the quality of noodles.

Table fare of the Virginia Mountains, S. B. HACKLEY (*What-to-Eat, 17 (1904), No. 2, pp. 78, 79*).—A popular descriptive article.

Results of borax experiment, H. W. WILEY (*U. S. Dept. Agr., Bureau of Chem-*

istry Circ. 15, pp. 27).—The investigations summarized have been noted from another publication (E. S. R., 16, p. 182).

Handbook of nutrition and dietetics in relation to therapeutics, E. von Leyden, revised by G. Klemperer (*Handbuch der Ernährungstherapie und Diätetik. Leipzig: Georg Thieme, 1903, vol. 1, pp. X+502, dgms. 2; 1904, vol. 2, pp. VIII+579, fig. 1*).—The general theories of nutrition in relation to the treatment of disease are discussed. The volumes are largely made up of special articles by different authors on a variety of topics related to the general subject under consideration. The introduction states that some of the chapters have been entirely rewritten.

Scope and results of the nutrition investigations in the United States, L. Grandeau (*Rev. Soc. Sci. Hyg. Aliment., 1 (1904), No. 1, pp. 1–17*).—A summary and discussion of the nutrition investigations which have been carried on under the auspices of the Office of Experiment Stations.

The value of sugar in the diet of soldiers, Boigey (*Caducée, 1904, Jan. 9; abs. in Rev. Soc. Sci. Hyg. Aliment., 1 (1904), No. 1, pp. 90, 91*).—It was found that when 40 gm. of sugar was added to the diet of soldiers for a long period gains in weight were made, but in a number of cases unfavorable symptoms resulted. In the abstract cited it was pointed out that this was to be expected, since a corresponding amount of other energy-yielding foods were not omitted when sugar was added to the ration.

Sugar in the diet of soldiers, Bienfait (*Caducée, 1904, Feb. 6, p. 40; abs. in Rev. Soc. Sci. Hyg. Aliment., 1 (1904), No. 1, p. 91*).—The author discusses Boigey's experiments on sugar and does not share his conclusions.

Statistical investigations of the diet of workmen, E. Waxweller (*Rev. Soc. Sci. Hyg. Aliment., 1 (1904), No. 1, pp. 17–24*).—A brief account of investigations regarding the diet of Belgium workingmen, conducted by the Solvay Institutes.

The utilization of vegetable proteids by the animal organism, E. W. Rockwood (*Amer. Jour. Physiol., 11 (1904), No. 4, pp. 355–369*).—Experiments with dogs and men are reported on the digestibility of oatmeal prepared in different ways and of separated oat proteid. When slightly cooked and well cooked oatmeal were compared, it was found in every case that the digestibility of the proteid was increased by long cooking, and "it is a natural supposition that this is the result of the breaking down of the cell walls and the easier access of the digestive enzyms to their contents."

In one series of experiments with dogs, meat, separated oat proteid, and malted oats were compared, and in another, oat proteid, rolled oats, meat, and zein. In these and the other experiments mentioned the balance of income and outgo of nitrogen was determined. Some of the results obtained follow:

Digestibility of protein of oats and other foods—Experiments with dogs.

Food.	Method of preparation.	Digestibility of protein.
		Per cent.
Meat with lard and cracker dust, average 4 tests	Raw	5.6
Malted oats	do	8.8
Coarse oatmeal, average 2 tests	Cooked 5 to 8 minutes.	17.5
Rolled oats	do	13.8
Oat proteid, first test	do	4.4
Oat proteid, second test	do	10.5
Zein, first test	do	22.4
Zein, second test	do	10.5
Fine oatmeal, average 2 tests	Cooked 4 to 6 hours	15.1

The principal conclusions drawn were in effect as follows: It is evident that without their removal from the materials associated with them the vegetable proteids are

not utilized to the same extent as those of animal origin. The degree of utilization is somewhat, although only slightly, increased by long cooking. Rolling out into thin flakes, as in the rolled oats, also appears to have some effect; but oats thus treated yield nearly as much fecal nitrogen as the others.

The technical process employed in the preparation of the malted oats seems to favor utilization, and this may be explained by their partial hydration. In one of the tests the extracted vegetable proteid was found to be as well utilized as the animal proteids. In the other test the agreement was less marked. In the former case the large amount of starch presumably kept the proteid particles from drying together into a comparatively impervious mass. "There is, consequently, no evidence from these experiments to indicate that the oat proteid, per se, is less readily utilized than is that of lean meat. This corresponds with the experience gained from feeding the vegetable proteid, edestin. . . .

"It may be objected that the presence of the milk [as part of the diet] . . . vitiates the conclusions derived from these trials. In all the experiments with dogs (except with zein feeding), the proportion of milk to the proteid studied was constant, and of the latter the same amount was used whenever practicable. Hence it is believed that the figures represent fairly the comparative degree to which the animals utilized the proteid.

"The greater fecal nitrogen from zein is probably not due so much to its being less digestible as to the insolubility of the substance and the inability of the digestive enzyms to act vigorously, except upon the surface of the impervious masses. When the zein was thoroughly dried its utilization was still further lessened. There is no reason to doubt that if the zein could be freed from the materials with which it is associated, except the starch, its utilization would be increased. The facilitating effect of the presence of starch was shown with the oat proteid in [one of the tests]. The achievement of means for removing the substances which interfere with digestion is worthy of study."

Absorption of diets rich in protein and fat and poor in protein and fat, J. König (*Ztschr. Untersuch. Nahr. u. Genussmtl.*, *7* (*1904*), *No. 9*, *pp. 529–545*).—Experiments on the digestibility by healthy men of a diet rich in protein and fat were carried on in cooperation with F. Reinhardt. The foods especially studied were young peas, ripe peas, purple cabbage, string beans, coarse rye bread, and Graham bread. They were combined with other foods to form a simple mixed diet of the character indicated.

It was found that the protein of purple cabbage, string beans, and coarse rye bread was not well assimilated, a larger part of the nitrogenous material of such food being excreted in the feces than was the case with wheat bread and shelled legumes. The crude fiber found in the feces contained more carbon than that contained in the food, which, in the author's opinion, shows that the crude fiber with low carbon content was generally digested, while the bodies having a high carbon content, such as lignin, accumulated in the feces in fairly large amounts. The digestibility of pentosans in these experiments has been noted from another publication (E. S. R., 13, p. 877).

Experiments on the digestibility of a diet with limited amounts of protein and fat were carried on in cooperation with Pollitz and H. Romberg. The results showed that when the diet contained meat and considerable fat, much less protein and fat was excreted in the feces than was the case with a diet containing limited amounts of protein (meat) and fat. The nitrogen-free extract was about equally digestible in the 2 cases, while pentosans and crude fiber were less digestible when small amounts of protein and fat were consumed.

Concerning phosphorus, calcium, and magnesium metabolism in adult man, R. Renvall (*Skand. Arch. Physiol.*, *16* (*1904*), *No. 12*, *pp. 94–138*, *pl. 1*).—The author, who was 22 years old, was himself the subject of the tests reported on the

metabolism of nitrogen and ash constituents. Full analyses of food and excretory products were made, the income and outgo of nitrogen, phosphorus, calcium, magnesium, and ash being determined.

In the author's opinion the results obtained with nitrogen were in accord with those of other investigators.

In the 32 days of the test the phosphorus in the mixed diet consumed ranged from 1.226 gm. to 2.105 gm. per day. On every day except one the total amount excreted was greater than the amount consumed. In other words, in the form in which it was consumed the amount of phosphorus was not sufficient for the body needs. However, in one period the amount consumed was 2.103 gm. per day and the average loss was only 0.030, showing that only a little more would have been required for equilibrium. During a supplementary period when the diet was selected without restriction the amount of phosphorus excreted was about the same as during the experiment proper.

As regards calcium, the author found that the larger proportion was excreted in the urine, though as he notes others have found that the feces contain the greater amount. It is pointed out that the observed facts may perhaps be explained by individual peculiarity or by the character of the food. The amount of calcium consumed ranged from about 0.9 to about 1.5 gm. Considering the test as a whole there was a small gain of calcium.

In the author's opinion the body was able to gain this element only in limited quantity. During part of the time some calcium carbonate was consumed, a portion of which was apparently resorbed. The author calculated that since the amount of calcium which he required was 1.2 gm., an older man, whose skeleton was completely formed, would require less than 0.7 gm. per day, considerations which would indicate that there is little danger of the supply in the food being inadequate to meet the body demands.

The amount of magnesium supplied by the diet was from about 0.4 to 0.6 gm. per day; when the larger amount was consumed there was a small gain. The magnesium requirement was calculated to be about 0.45 gm. per day. About 30 per cent of the magnesium consumed was excreted in the urine and 70 per cent in the feces.

The diet supplied from about 30 to 38 gm. total ash per day. Considering the test as a whole there was a loss of 31.2 gm. The amount not accounted for by the ash constituents measured, it is pointed out, must have been made up largely of sodium, potassium, and chlorin. The author notes that in the urine the principal ash constituent is sodium chlorid and in the feces phosphoric acid.

The author and 2 other young men were the subjects of some tests which were undertaken to ascertain the amount of nitrogen, phosphorus, calcium, and magnesium in the intestinal secretions. The diet consisted of sago cooked in water, sweetened with sugar, and flavored with a little citric acid and raspberry juice. In 2 tests reported the nitrogen in the feces amounted to 1.5 and 1.52 gm. per day, the phosphorus 0.223 and 0.229, calcium 0.163 and 0.165, and magnesium 0.064 and 0.067.

In one test the fat in the feces was determined and amounted to 2.5 gm. per day. The results obtained are discussed at length and compared with those of other investigators. The author notes that when small amounts of ash constituents are supplied, the body limits the amounts excreted. Since the energy requirements of the body were nearly supplied by the diet furnished, smaller amounts of body tissue were broken down than would be the case in fasting.

A new apparatus for studying the respiratory metabolism of man, A. Jaquet (*Verhandl. Naturf. Gesell. Basel, 15 (1904), No. 2, pp. 252–271, pl. 1*).—A respiration apparatus, which is designed especially for studying the respiratory quotient with men, is described. The apparatus consists of a respiration chamber, its capacity being 1,387 liters, provided with a folding bed and other conveniences, windows for lighting, telephone, and a food aperture for the convenient introduction of food into

the respiration chamber and the removal of excreta. The respiration chamber is of such size that a man may remain in it in comparative comfort for a period of twenty-four hours. The air drawn through the respiration chamber is measured with a gas meter and aliquot samples analyzed.

Alcohol check experiments, which are very briefly reported, led the author to conclude that the apparatus is very accurate. Some analytical data of experiments with men are also given. The simplicity of construction of the apparatus is, in the author's opinion, a point in its favor.

Concerning the action of sulphur on proteid bodies, M. HAUSMANN and A. HEFFTER (*Beitr. Chem. Physiol. u. Pathol., 5 (1904), No. 5-6, pp. 213-233*).—It has been observed that when white of egg is treated under proper conditions with finely divided sulphur, hydrogen sulphid is produced. The authors studied this reaction at length with egg white and other proteids.

According to their investigations it appears that crystallized ovalbumin, and perhaps also conalbumin, as well as an unidentified proteid found in animal tissue, possess the property of forming hydrogen sulphid from sulphur at an ordinary temperature (40° C.) and do not lose this property when cooked. The reaction was also produced by a body in blood cells, but whether in the case of this substance also the reaction was unaffected by cooking, and the body therefore was to be classed with the similar substance obtained from organs, can not be stated.

All proteid bodies do not possess the property of forming hydrogen sulphid from sulphur at room temperature. It was found that the globulins of white of egg and blood serum, fibrin, serum albumin, the proteids of milk and other secretions did not possess it. Neither did Witte peptone and commercial hemialbumose form hydrogen sulphid. Gelatin and yeast nuclein were also found to be inactive at room temperature. When cleavage was induced in ovalbumin and probably in the other active proteids by pepsin, the active properties were destroyed.

A number of experiments were carried on to ascertain the cause of the observed phenomena. It was found that a formation of hydrogen sulphid from sulphur was brought about by a number of mercaptans, and it is suggested that in the case of proteids the reaction may be due to the presence of mercaptan radicals.

Certain questions which have to do with proteid metabolism, W. FALTA (*Verhandl. Naturf. Gesell. Basel, 15 (1904), No. 2, pp. 206-224, pl. 1*).—The experiments reported have to do with the source of nitrogenous excretory products and the cleavage of protein in the body.

The effect of pancreas upon proteid formation, P. BERGELL and F. BLUMENTHAL (*Arch. Physiol. [Pflüger], 103 (1904), No. 11-12, pp. 627-631*).—Experimental data are reported and discussed.

The effect of sea climate and sea baths upon metabolism in man, A. LOEWY and F. MÜLLER (*Arch. Physiol. [Pflüger], 103 (1904), No. 9-10, pp. 450-475, figs. 2*).—The experiments reported showed that sea climate and sea baths have an effect on metabolism with certain persons, but did not show the reasons for this.

Phosphorus medication: Glycero-phosphates, lecithins, nucleins, H. LABBÉ (*La médication Phosphorée: Glycero-phosphates, lécithines, nucléines. Paris: J. B. Baillière & Sons, 1903, pp. 96; rev. in British Med. Jour., 1904, No. 2267, p. 1374*).—The faulty assimilation of phosphorus and inorganic phosphorus compounds is spoken of. More favorable results attend the use of organic compounds, and the author discusses lecithins, nucleins, and similar bodies.

Concerning myogen, a new protein preparation, R. O. NEUMANN (*München. Med. Wchnschr., 50 (1903), pp. 106-108; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 7 (1904), No. 9, p. 557*).—A descriptive article.

The utilization of heat produced by animals, L. GRANDEAU (*Jour. Agr. Prat., n. ser., 7 (1904), No. 23, pp. 737, 738*).—A discussion from a quantitative standpoint of the energy outgo of the body.

The estimation of carbohydrates in feces, S. WEISER and A. ZAITSCHEK (*Landw. Vers. Stat., 58 (1903), Nos. 3–4, pp. 232–237*).—From experiments reported the conclusion was drawn that it is absolutely necessary to estimate the amount of pentosans present in feces whenever their starch content is taken into account.

The sulphurous acid of foods bound in organic compounds, K. FARNSTEINER (*Ztschr. Untersuch. Nahr. u. Genussmtl., 7 (1904), No. 8, pp. 449–470*).—The author studied especially the form in which sulphurous acid is found in fruit products and its union with carbohydrates.

The formation of sugar from fat, E. ABDERHALDEN and P. RONA (*Ztschr. Physiol. Chem., 41 (1904), No. 4, pp. 303–307*).—Attempts to form sugar from fat by treating olive oil and oleic acid with sheep liver were not successful, but as the author notes the experiments reported do not preclude the possibility of such formation in the body.

The influence of fat in the diet on the renal excretion of ammonia, F. STEINITZ (*Zentbl. Inn. Med., 25 (1904), p. 81; abs. in Zentbl. Physiol., 18 (1904), No. 3, p. 85*).—It was noted that ammonia excretion increased with the amount of fat eaten while sodium and potassium excretion decreased. The experiments were made with children and the salt content of the diet was kept constant.

The dietetic value of the legumes, MARY L. VAN ZILE (*Iowa Agr., 4 (1904), No. 3, pp. 117, 118*).—A popular summary.

The influence of external hemorrhage on chemical changes in the organism, with particular reference to proteid catabolism, P. B. HAWK and W. J. GIES (*Amer. Jour. Physiol., 11 (1904), No. 3, pp. 171–236*).—The experiments reported were made with dogs. The elimination of nitrogen, phosphorus, chlorin, and sulphur was one of the questions studied.

The end products of self digestion of animal organs, I, P. A. LEVENE (*Ztschr. Physiol. Chem., 41 (1904), No. 5, pp. 393–403*).—A contribution to the subject of digestion and digestive ferments.

The final products of autodigestion of pancreas, III, KUTSCHER and LOHMANN (*Ztschr. Physiol. Chem., 41 (1904), No. 4, pp. 332–342*).—Experimental data are reported.

Calorimetric studies of feces, H. LOHRISCH (*Ztschr. Physiol. Chem., 41 (1904), No. 4, pp. 308–320*).—In the author's opinion, determining the heat of combustion of feces furnishes valuable data for judging of the utilization of different foods. Experimental data are reported, including the heat of combustion of the food, feces etc., in experiments with man.

The paths of excretion for inorganic compounds. I, The excretion of strontium, L. B. MENDEL and H. C. THACHER (*Amer. Jour. Physiol., 11 (1904), No. 1, pp. 5–16*).—The authors' conclusions drawn from the experiments reported follow: "Strontium salts are eliminated to a relatively small extent only by the kidneys, even after direct introduction into the circulation. The excretion in the urine begins soon, and ceases usually within 24 hours. The larger portion of the strontium eliminated is found in the feces, whether the introduction of the element be per os, subcutaneously, intravenously, or intraperitoneally.

"The place of excretion is apparently restricted to the region of the alimentary tract beyond the stomach. A functional relation to certain phenomena of intestinal peristalsis, etc., is suggested. The rate of elimination is slow, and is apparently influenced by the calcium content of the food. Strontium is found deposited in the body chiefly in the bones; traces may be met with in the liver and muscles."

Experiments on the physiological action of the active substances of organs and tissues, A. PUGLIESE (*Jour. Physiol. et Path. Gén., 6 (1904), No. 3, pp. 452–465, dgms. 12*).—Results of a number of experiments are reported.

The retarding of peptic activity by salts, J. SCHÜTZ (*Beitr. Chem. Physiol. u.*

Pathol., *5* (*1904*), *No. 9*, *pp. 406–411*).—From a number of experiments the conclusion was reached that anions hinder peptic digestion within wider limits than cations, sodium being generally the strongest of the cations. Other conclusions are also drawn which have to do with the subject considered from the standpoint of the theories of physical chemistry.

General relations between heat of combustion of organic compounds and their structural formulæ. Calculations of the heat of combustion, P. Lemoult (*Ann. Chim. et Phys.*, *8. ser.*, *1* (*1904*), *Apr.*, *pp. 496–553*).—A theoretical and mathematical discussion.

A note on pancreas-nucleoproteid, P. A. Levene and L. B. Stookey (*Ztschr. Physiol. Chem.*, *41* (*1904*), *No. 5*, *pp. 404–406*).—Analytical and other data are reported.

Concerning the history of the discovery of the relationship between chlorophyll and the coloring matter of the blood, L. Marchlewski (*Arch. Physiol.* [*Pflüger*], *102* (*1904*), *No. 1–2*, *pp. 111–115*).—A historical and controversial article.

Experiments on the behavior of liver cells, especially as regards physical-chemical relations, E. Petry (*Beitr. Chem. Physiol. u. Pathol.*, *5* (*1904*), *No. 5–6*, *pp. 245–275*).—The absorption of chlorin was especially studied with reference to the properties and behavior of liver cells.

Physical deterioration, its causes and the cure, Mrs. A. W. Smyth (*London: John Murray*, *1904*, *pp. 334*; *rev. in British Med. Jour.*, *1904*, *No. 2266*, *pp. 1317*, *1318*).—Among other topics the author discusses milk supplies and the effect of food upon the physical condition of children.

Food requirements of infants, Barbier (*Ann. Hyg. Pub. et Méd. Lég.*, *1904*, *Apr.*, *p. 379*; *abs. in Rev. Soc. Sci. Hyg. Aliment.*, *1* (*1904*), *No. 1*, *p. 90*).—The food requirements of infants are discussed and a formula quoted for calculating the needed quantity of milk.

Food requirements of new-born infants, V. Bué (*Presse Méd.*, *1904*, *Mar. 2*; *abs. in Rev. Soc. Sci. Hyg. Aliment.*, *1* (*1904*), *No. 1*, *pp. 88–90*).—A summary and discussion.

ANIMAL PRODUCTION.

Fodders and feeding stuffs, F. T. Shutt (*Canada Expt. Farms Rpts. 1903*, *pp. 134–144*).—Analyses are reported of oats, whole grain, kernels, and hulls; brans and shorts, molasses feeds, dried beet pulp, cotton-seed meal, mangel-wurzels, carrots, and turnips.

Handbook of animal feeding and feeding stuffs, E. Pott (*Handbuch der tierischen Ernährung und der landwirtschaftlichen Futtermittel. Berlin: Paul Parey*, *1904*; *vol. 1*, *pp. X+389*).—A second edition of this handbook which the author states has been thoroughly revised and now will appear in 2 volumes. The first volume takes up the general theories of nutrition; composition, feeding value, and valuation of feeding stuffs; effect of soil and other conditions of growth on feeding value, and related topics.

Report of the Louvain laboratory, J. Graftiau (*Rap. Trav. Lab. Anal. Louvain*, *1903*, *pp. 15*).—Analyses of a number of samples of fertilizers and feeding stuffs are reported, and data given regarding the work of the Louvain laboratory, including studies of the ash content of plants as affected by factory fumes.

Chemical analyses of meadow grasses, C. E. Bessey (*Breeder's Gaz.*, *45* (*1904*), *No. 25*, *pp. 1182*, *1183*).—An analysis of meadow hay is quoted.

Feed for domestic animals in Norway, H. Bordewich (*Dept. Com. and Labor, Mo. Consular Rpts.*, *75* (*1904*), *No. 283*, *p. 293*).—A brief note regarding the importation of American corn and cotton-seed meal into Norway, with suggestions for increasing the trade by proper methods of manufacture and packing.

Dried brewers' grains and distillers' grains, DIETRICH (*Landw. Vers. Stat., 58 (1903), No. 3-4, pp. 241-262, figs. 18*).—A number of forms of apparatus for drying brewers' and distillers' grains are described.

Oats, E. HASELHOFF and F. MACH (*Landw. Vers. Stat., 60 (1904), No. 3-4, pp. 161-206, pls. 2*).—Data regarding the composition, structure, and feeding value of oats and oat products and related topics are summarized and discussed.

Composition and food value of the leaves of sugar beets, L. GRANDEAU (*Jour. Agr. Prat., n. ser., 8 (1904), No. 30, pp. 106-108*).—A summary of data on this topic.

The terminology of the constituents of feeding stuffs, A. GRÉGOIRE (*Bul. Cercle d'Études Agron. [Brussels], 1903, No. 8, pp. 369-375*).—The terminology proposed for the constituents of feeding stuffs is practically the same as that followed in the United States, Germany, and elsewhere.

The digestibility of peat as an absorbent for molasses in molasses feeds, T. PFEIFFER and A. EINECKE (*Mitt. Landw. Inst. Univ. Breslau, 2 (1904), No. 4, pp. 683-694*).—Experiments with sheep showed that an appreciable quantity of the total organic material, nitrogen-free extract, and pentosans of peat meal was digested. The author calls attention to the fact that molasses peat has more value than is ordinarily believed.

The digestibility of pentosans, S. WEISER (*Landw. Vers. Stat., 58 (1903), No. 3-4, pp. 238-240*).—Experiments are briefly reported on the digestibility of pentosans by steers, pigs, sheep, and a horse. The coefficients of digestibility varied within rather wide limits with the different animals and in different experiments with the same animals, but on an average this constituent was quite thoroughly digested. As shown by the experiments reported the digestibility of pentosans is parallel to and varies directly with that of carbohydrates.

The fate of pentosans (xylans) in the animal body, B. SLOVTZOV (*Izv. Imp. Akad. Nauk [Bul. Acad. Imp. Sci. St. Petersburg], 5. ser., 15 (1901), pp. 423-434; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 8 (1904), No. 2, p. 157*).—From experiments with separated ferments and with guinea pigs, the conclusion was drawn that when xylan is consumed by herbivora in small quantities a portion at least is resorbed and serves as a nutrient. The digestive ferments did not act upon xylan, but hydrochloric acid changed some of it into xylose.

Concerning the resistance of true albumin to tryptic digestion in the animal body, S. ROSENBERG and C. OPPENHEIMER (*Beitr. Chem. Physiol. u. Pathol., 5 (1904), No. 9, pp. 412-421*).—From experiments with a dog with a fistula carried on in continuation of earlier work[a] the conclusion was reached that in the body as well as in vitro true albumin is resistant to the action of tryptic ferments.

Concerning the influence of alkalis on protein metabolism, E. DUFOURT (*Jour. Physiol. et Path. Gén., 6 (1904), No. 3, pp. 489-496*).—Experiments with dogs on a meat and on a vegetable diet are reported, the alkali studied being bicarbonate of soda in varying doses. According to the author the alkali increased the urea excretion as compared with the total renal nitrogen both on a vegetable and on a meat diet. The experiments are discussed at some length.

Sweet clover as a stock feed, G. H. OTIS (*Breeder's Gaz., 46 (1904), No. 2, p. 54*).—Contrary to the general opinion, the author on the basis of experience considers sweet clover hay a satisfactory feed for farm animals, including horses and mules; however, he recognizes the fact that it is necessary to first accustom them to its use. In his opinion it should be cut early and handled like alfalfa. The value of sweet clover for binding soil on washed-out and abandoned limestone lands is also spoken of.

On the distribution of osseomucoid, C. SEIFERT and W. J. GIES (*Amer. Jour. Physiol., 10 (1903), No. 3, pp. 146-148*).—Experiments with mammals, birds, reptiles,

[a] Beitr. Chem. Physiol. u. Pathol., 4 (1903), p. 279.

and a fish led to the conclusion that osseomucoid is very probably a normal constituent of all bones.

The reaction of the urine of Bovidæ, A. GOUIN and P. ANDOUARD (*Bul. Sta. Agron. Loire-Inférieure, 1902–3, pp. 101–105*).—Brief notes on the subject.

Animal feeding, A. STUTZER (*Fütterungslehre. Leipzig: Hugo Voigt, 1904; rev. in Ztschr. Landw. Versuchsw. Oesterr., 7 (1904), No. 6, pp. 492, 493*).—The fourth edition of this work, which is designed for the use of agricultural students, it is stated has been thoroughly revised.

Live stock, J. H. GRISDALE (*Canada Expt. Farms Rpts. 1903, pp. 57–59*).—Brief statements are made regarding the cattle, sheep, swine, and horses at the Ottawa Experimental Farm.

Hybridism among birds, E. DÍAZ (*An. Acad. Cien., Habana, 38 (1902), pp. 231–233, pls. 2*).—The author presents 2 illustrations furnished by the owner of fowls claimed by the latter to be crosses between the turkey and guinea hen. Brief notes are given on the difficulties of obtaining crosses between different genera of domestic fowls and on the distinguishing characteristics of this particular cross.

On the relation of autolysis to proteid metabolism, H. G. WELLS (*Amer. Jour. Physiol., 11 (1904), No. 4, pp. 351–354*).—In the experiments reported it did not appear that extracts of thyroid, kidney, and spleen had any decided effect on the autolysis of the liver of the dog.

Changes in races of Bovidæ as related to the geological origin of soils, A. GOUIN (*Bul. Soc. Agr., Sci. et Arts, Sarthe, 2. ser., 31 (1904), No. 3, pp. 240–262*).—A theoretical discussion of the subject.

Experiment with steers, R. ROBERTSON, S. A. BEDFORD, and A. MACKAY (*Canada Expt. Farms Rpts. 1903, pp. 284, 287–294, 333–336, 392–394*).—The relative merits of feeding steers loose and tied in stalls were studied at the Maritime Provinces Farm with 2 lots of 8 dehorned steers, each fed similar rations of hay, roots, silage, and mixed meal for 150 days. The total gain made by the loose steers was 2,435 lbs. and by the tied steers 2,250 lbs.

In a comparison of full fattening and limited growing rations it was found that a lot of 5 calves on a full fattening ration made an average daily gain of 2.32 lbs. at a cost of 6 cts. per pound for 150 days. Similar values for 5 calves fed the limited growing ration for a year were 0.86 lb. and 5.30 cts. In a second test the steers fed the full fattening ration made an average daily gain of 1.44 lbs. at a cost of 5.21 cts. per pound, and with those on a limited growing ration the average daily gain was 0.95 lb. per steer and the cost of a pound of gain 3.64 cts. The above tests were made in continuation of those previously reported (E. S. R., 15, p. 172).

At the Manitoba Experimental Farm brome-grass hay was compared with corn fodder, using 2 lots of 5 steers each. The lots were all fed turnips, chopped mixed grains, and bran in addition to the coarse fodders mentioned, and were handled similarly. In the 32 weeks of the test the steers fed brome-grass hay made an average daily gain of 1 lb. 10 oz. and those fed corn fodder 1 lb. 12 oz. According to the authors' calculations the profits were, respectively, 64 and 71 cts. per steer in the 2 lots.

"There is very little profit in feeding steers when the difference between the buying and selling price is only about 75 cts. per steer. Cattle require more pounds of fodder corn per day than they do of brome-grass hay. The comparative value of these 2 fodder crops is about $4 per ton for fodder corn and $5 for brome hay."

The gains made by steers turned out 2 hours each day, as compared with those kept continually in the stable, were studied at the Indian Head Farm with 2 lots of 5 animals each fed under uniform conditions. In the case of the steers turned out a part of each day the total gain in the 180 days of the test was 1,520 lbs. and the calculated profit per steer $2.14 as compared with 1,615 lbs. and $2.74 for the steers confined all the time.

In connection with the experiments brief notes are given regarding the cattle kept at the several experimental farms.

Cattle: Beef production, J. H. Grisdale (*Canada Expt. Farms Rpts. 1903, pp. 57, 58, 67–79*).—The station herd is briefly described and feeding tests are reported in continuation of earlier work (E. S. R., 15, p. 172). In a study of the relative merits of handling steers, 9 animals tied in stalls and having an average of 56 sq. ft. of space per steer gained 1.58 lbs. per head per day, the cost of a pound of gain being 7.05 cts. The test covered 180 days.

In the case of a similar lot of loose steers with an average of 84 sq. ft. of space per steer the average daily gain per head was 1.87 lbs., the cost of a pound of gain being 5.32 cts., while 9 loose steers having 38 sq. ft. of space per steer made an average daily gain of 1.52 lbs. per steer, the cost of a pound of gain being 6.58 cts. The steers in the last two mentioned lots were dehorned. All were fed a ration of gluten meal, silage, roots, and hay.

In a study of the influence of age on the cost of beef production it was found that a lot of 9 3-year-old steers in 180 days made an average daily gain of 1.58 lbs., the cost of a pound of gain being 7.05 cts. Similar values in the case of 9 2-year-old steers were 1.65 lbs. and 6.03 cts., with a lot of 9 yearlings 1.65 lbs. and 5.54 cts., with a lot of 6 calves 6 months old 1.46 lbs. and 5.33 cts., and with a lot of 6 new-born skim-milk calves 1.48 lbs. and 2.16 cts.

In every case the coarse food consists of roots, silage, fodder, and hay. The steers and yearlings were fed gluten meal in addition and the calves a grain ration made up of different proportions of oats, peas, barley, oil meal, and gluten meal. The new-born calves were also given some skim milk. "In cost of production there is a quite remarkable gradation in favor of the younger classes."

In a comparison of feeding heavy rations from birth to block and feeding in the usual way, that is, a limited growing ration for the first 5 or 6 months and then a fattening ration until the time of slaughtering, it was found that 6 steers fed a full fattening ration gained 1.18 lbs. per head per day for 365 days, the cost of a pound of gain being 6.13 cts. An equal number of steers fed the same length of time the limited growing ration gained 0.96 lb. per day, the cost of a pound of gain being 6.22 cts. Five calves fed a full fattening ration for 184 days made an average daily gain of 1.48 lbs. at a cost of 2.16 cts. per pound.

Beef cattle breeding in Argentina, F. W. Bicknel (*Breeder's Gaz., 46 (1904), Nos. 5, pp. 166–168; 6, pp. 208, 209, figs. 8*).—The extent and condition of the cattle industry in Argentina are discussed.

To estimate the weight of cattle by measuring with a tape line, R. West (*Jour. Jamaica Agr. Soc., 8 (1904), No. 7, p. 285*).—Brief directions are given for estimating the weight of cattle from external measurements.

Calf-rearing experiments, second year, 1902 (*Jour. Dept. Agr. and Tech. Instr. Ireland, 4 (1904), No. 3. pp. 415–427, dgms. 2*).—In continuation of earlier work (E. S. R., 15, p. 802) the possibility of rearing calves on cream substitutes was studied with 3 lots of 9 and 1 lot of 8 calves under practically the same conditions as in the earlier test. For 20 weeks lot 1 received a whole milk ration, lot 2 a mixture of whole and skim milk, lot 3 skim milk with the addition of cod-liver oil, and lot 4 skim milk with a mixture of meals. The greatest gain, 291.5 lbs., per head was made on the whole milk and the least gain, 244.1 lbs., on skim milk and cod-liver oil.

The test was continued under uniform conditions after weaning to judge of the effect of the rations mentioned on subsequent gains. Considering the whole period, which covered 73 weeks, the greatest gain, 625.9 lbs., per head was made on whole milk and the smallest gain, 531.8 lbs., per head on a mixture of whole and skim milk. The whole milk ration was the most expensive. The greatest saving by using whole milk substitutes amounted to \$5.28 per head and was noted with the ration composed of a mixture of whole and skim milk.

From this and the earlier experiments the conclusion was drawn that "although calves fed for a long period on whole milk will show a high rate of increase when compared with the gain in weight made by animals reared on other foods, the increase is not proportional to the cost incurred. It is much more economical to use a cream substitute, such as linseed cake, with cod-liver oil, Indian meal, or a mixture of meals, along with separated milk than to use whole milk and linseed cake."

New experiments on the feeding of calves, A. GOUIN and P. ANDOUARD (*Bul. Sta. Agron. Loire-Inférieure, 1902–3, pp. 66–100*).—In continuation of work previously reported (E. S. R., 14, p. 1105), the author studied the water content of flesh, and the effect of acid potassium phosphate, dried calcium phosphate (the natural mineral), powdered green bone, arsenite of potash, hydrochloric acid, and bicarbonate of soda upon the assimilation of food, the metabolism of nitrogen, and the gains made by calves.

His previous deduction as to the value of powdered bone in inducing gains was confirmed. The conclusion was reached that calves require smaller amounts than the Wolff standard calls for; for instance, during 98 days one of the calves consumed 1,947 gm. of dry matter and digested 1,245 gm., the gain made amounting to 852 gm., as compared with 1,740 gm. digestible nutrients, and 550 gm. gain, called for by the German standards.

Depreciation of leather by brands, J. MEHMKEN (*Breeder's Gaz., 46 (1904), No. 4, p. 130, dgm. 1*).—The author discusses the effect of branding upon the value of the dressed hide and points out that the least injury results when branding is done on the jaw. The most damage is caused by the side brand, the hip brand being regarded as between the two in this respect.

The sheep industry of the Laramie Plains, F. S. KING (*Ranchman's Reminder, 1 (1904), No. 7, pp. 83–87, figs. 4*).—The early history of the local sheep industry is briefly spoken of.

Sheep, R. ROBERTSON (*Canada Expt. Farms Rpts. 1903, p. 295*).—Brief notes are given regarding the Maritime Provinces Farm flock.

Swine, R. ROBERTSON, S. A. BEDFORD, and A. MACKAY (*Canada Expt. Farms Rpts. 1903, pp. 294, 295, 336, 337, 394*).—In continuation of tests previously reported (E. S. R., 15, p. 174) the relative merits of pasturing pigs and feeding in pens was tested at the Maritime Provinces Farm with 2 lots of 10 animals each. The lot pastured for 4 months and then fed in a pen for 1 month made an average daily gain of 1.06 lbs. per head, at a cost of 3.04 cts. per pound, as compared with 0.8 lb. and 4.05 cts. in the case of the lot fed in the pens for the entire period.

At the Manitoba Experimental Farm 4 pigs fed spelt gained 389 lbs. as compared with 407 lbs. in the case of a similar lot fed mixed grain, the calculated profit in the two cases being \$8.99 and \$9.75. "The pen of animals fed on mixed grain consumed 25 lbs. more grain during the fattening period than those fed on spelt."

In addition to the feeding tests brief notes are given regarding the swine kept at the Maritime Provinces, Manitoba, and Indian Head experimental farms.

Millet for fattening swine, J. W. WILSON and H. G. SKINNER (*South Dakota Sta. Bul. 83, pp. 15, figs. 5*).—Using 3 lots of 2 pigs each the relative value of ground barley, hog millet (*Panicum miliaceum*), and wheat was studied. These grains were mixed with water and fed ad libitum. In the 84 days of the test the average daily gain per head on barley was 1.25 lbs., the feed eaten per pound of gain being 4.95 lbs. Similar values for millet were 1.13 lbs. and 5.95 lbs., and for wheat 1.67 lbs. and 4.87 lbs. It was noticed that the lot receiving millet relished their feed and were in apparently as good physical condition during the whole test as the other lots.

Considering the test as a whole the authors calculate that the barley and millet each returned 41 cts. and the wheat 52 cts. per bushel. An examination of similar cuts from the dressed carcasses showed that the percentage of fat to lean in the mil-

let-fed pork was much smaller than in the other samples. All the pork was considered too fat for local trade and the authors believe that the pigs might have been more advantageously slaughtered earlier.

The lean meat from the lots fed millet and wheat was lighter in color than that from the barley-fed lot. The fat from the lot fed millet was pure white and although not so firm in texture it was considered superior in quality to that of the other carcasses, which had a yellowish tinge. An analysis of the millet fed is reported.

The utilization of skimmed milk in feeding pigs, H. H. WING (*New York Cornell Sta. Bul. 220, pp. 189–197*).—Skim milk is frequently sold for the manufacture of casein and similar purposes, returning to the producer not over 10 cts. per 100 lbs. A test was therefore undertaken with 6 lots containing from 7 to 12 pigs each, to see if it could not be more profitably utilized as a feeding stuff.

In addition to skim milk lots 1 and 3 were fed corn meal, lots 2 and 5 corn meal and gluten feed 1:1, and lots 4 and 6 corn meal and wheat middlings 1:1. Considering the results as a whole the average daily gain for the 83 days of the test was 0.99 lb. on corn meal, 0.93 lb. on corn meal and gluten feed, and 0.96 lb. on corn meal and wheat middlings, the skim milk fed per pound of gain averaging 3.5, 4.3, and 4.7 lbs. in the 3 cases.

From the results of the trial the author calculates that on the whole skim milk is worth about 15 cts. per cwt. when fed to pigs from the time of weaning until they weigh about 125 lbs.

"Clear corn meal is perfectly satisfactory as a single grain when fed in connection with skimmed milk.

"Weanling pigs in close quarters during cold weather can be made to gain a pound live weight per day for 3 months.

"There are indications that the proportion of skimmed milk can be increased economically above the ratio of 3 lbs. of milk to 1 lb. of grain usually recommended, thus lessening the amount of grain food that must be purchased."

Poland-China and Berkshire pigs, F. L. CLARKE (*Jour. Jamaica Agr. Soc., 8 (1904), No. 7, pp. 275, 276*).—The author discusses pig breeding under local conditions and gives briefly the results of his experience with Poland-China and Berkshire pigs.

Horses, R. ROBERTSON and A. MACKAY (*Canada Expt. Farms Rpts. 1903, pp. 284, 304*).—Brief statements are made regarding the horses kept at the Maritime Provinces and Indian Head experimental farms.

The horse industry in Australia, W. G. MCKINNEY (*Jour. Dept. Agr. West. Australia, 9 (1904), No. 5, pp. 321–334*).—A descriptive and statistical article.

Results of scientific feeding of plantation mules, W. GODCHAUX (*Proc. Louisiana State Agr. Soc. and Stockbreeders' Assoc., 1904, pp. 71–79*).—The rational feeding of mules is discussed and data given regarding the system at present followed at a large sugar factory at Assumption Parish, Louisiana, as compared with the system previously followed.

The ration now fed consists of 8 lbs. of corn-and-cob meal, 2 lbs. cotton-seed meal, 11 lbs. molasses, and 15 lbs. pea-vine hay, the cost being 14.5 cts. per head. According to the author's calculations this would supply the nutrients and energy called for by Wolff's standard for horses or mules at heavy work. The author states that the use of this ration has diminished the cost of feeding mules nearly half, while at the same time their health has improved.

Cuba's beasts of burden, F. C. GILTNER (*Breeder's Gaz., 46 (1904), No. 3, pp. 88–90, figs. 8*).—The author describes the horses, mules, and cattle used as beasts of burden in Havana and the rural districts of Cuba.

Report of the poultry manager, A. G. GILBERT (*Canada Expt. Farms Rpts. 1903, pp. 239–255, pl. 1*).—The important factors in the production of a superior quality of

poultry, breeds and strains, the local price for eggs, and other conditions affecting poultry raising are spoken of, and brief notes are given regarding the experimental work of the poultry department, the rations fed, and the results of incubator tests, as well as data regarding the number of eggs laid during the year and the stock kept at the station poultry farm. The information gained in connection with testing and hatching eggs laid during the cold season is summarized as follows:

"The generous and gently stimulating rations given to the fowls kept in cold houses did not seem to affect the strength of the germs of the eggs laid by them, as similar rations apparently did in the case of the hens kept in artificially warmed quarters.

"Eggs laid in early December by the hens in artificially warmed houses showed a greater percentage of strong germs than did eggs laid by them later in the season.

"Eggs laid by the same hens in early spring showed a satisfactory percentage of fertility, but the weakest germs.

"The most striking and gratifying results were obtained from the fowls which, like their parent stock, had never known warm quarters. From 55 eggs laid by these fowls in early spring—after laying well during the winter—48 strong chickens were hatched. In contrast with this are 17 chickens from 52 eggs laid by hens kept in warmed but comparatively limited quarters.

"Results were strongly in favor of the average farm conditions."

Poultry, R. Robertson, S. A. Bedford, and A. Mackay (*Canada Expt. Farms Rpts. 1903, pp. 296, 337, 338, 394*).—At the Manitoba farm 4 Barred Plymouth Rock cockrels fed in pens a mixture of equal parts of finely ground wheat, barley, and oats, mixed to a thin porridge with skim milk, gained 5 lbs. 8 oz. in 28 days, the cost of a pound of live weight being 4 cts. Four Wyandotte cockrels fed the same ration under the same conditions gained 4 lbs., the cost of a pound of live weight being 5.25 cts.

Brief statements are also made regarding the work of the poultry department at the Maritime Provinces, Manitoba, and Indian Head experimental farms.

The poultry industry (*Maine Dept. Agr. Bul., 3 (1904), No. 2, pp. 55–81*).—This bulletin includes popular articles which have to do with poultry raising and data regarding the present condition of the poultry industry in Maine.

A representative English poultry plant (*Reliable Poultry Jour., 11 (1904), No. 6, pp. 631–635, figs. 5*).—A descriptive article which discusses among other topics the sale of day-old chicks and so-called live eggs—that is, incubated eggs—which examination has shown contain live chickens within 3 days of hatching.

Experiments in chicken fattening, F. T. Shutt (*Canada Expt. Farms Rpts. 1903, pp. 256–260*).—The relative merits of fattening chickens in pens and crates was studied with 4 lots of 6 chickens each. In the case of the 2 lots fed in pens the average gain per chicken in the 4 weeks covered by the test was 1 lb. 9.33 oz. and 2 lbs. 4.5 oz., the cost of a pound of gain being 6.7 cts. and 5.3 cts., respectively.

In the case of the lots fed in crates the average gain per chicken was 1 lb. 9.66 oz. and 2 lbs. 2.33 oz., the cost of a pound of gain being 6.2 cts. and 5.6 cts. The proportion of edible and nonedible portions in the dressed chickens was recorded in both cases, the proportion of dressed carcass being the larger in the case of the chickens fed in crates, while the flesh of the pen-fed birds, it is stated, was slightly the yellower.

The results of the present test, it is noted, are apparently contradictory to those previously obtained (E. S. R., 15, p. 176). "It is possible that the more favorable temperature for the crated birds this season was the predominating factor in altering the relative economy of the two systems of feeding. The question of temperature appears to be one well worthy of further investigation."

The relative value of all grain and grain-and-meat rations was studied with 2 lots each containing 5 Barred Plymouth Rock cockrels, the ration of the former lot being

made up of ground oats and barley 4:3 fed with skim milk, and that of the latter ground oats, barley, and meat meal 4:3:1. In the 4 weeks of the test the average gain per chicken on the grain ration was 1 lb. 13.5 oz. and the cost of feed per pound of gain 5.4 cts. Similar values for the grain-and-meat ration were 2 lbs. 0.6 oz. and 5.6 cts.

"These results show an increased efficiency for the ration containing the meat scrap. When, however, the relative cost of the ration is taken into account, the 'all grain' has slightly the advantage (by reason of it costing less), the difference being two-tenths of a cent per lb. of increase more in the case of the 'grain and meat' ration.

"On killing and dressing, the two lots were found to be remarkably similar as regards plumpness and weight, due largely, the writer thinks, to the uniformity of type. They furnished identical data as regards the percentage of dressed carcass, and were only distinguished into groups by the slightly yellow tinge of the 'all-grain' fed birds; the chickens from the 'grain and meat' ration gave a perfectly white flesh."

Growth of chickens and cost of rearing, E., E. T., and W. Brown (*Reprinted from Poultry, 1904, July 22, pp. 4*).—At the Reading University College Poultry Farm the comparative merits of White Wyandottes and crossbreeds were tested under uniform conditions. White Wyandottes made an average gain of 2.17 lbs. and the crossbreeds of 2.26 lbs. in 12 weeks, the cost of a pound of gain in the 2 cases being 6.96 cts. as compared with 6.68 cts. The crossbred birds were at a disadvantage, in the authors' opinion, in that 3 different crosses were used. The Faverolles-Buff Orpington was the most profitable. The quality of the flesh of the dressed birds is briefly discussed.

It is evident, according to the authors, "that the larger profit is obtained in producing market chickens by breeding from the table varieties of poultry. Further, they must be salable at the right season, when prices for spring chickens are good."

Laying competitions, B. W. Horne (*Jour. British Dairy Farmers' Assoc., 17 (1902), pp. 40-49*).—The importance of laying competitions is briefly spoken of and data regarding those carried on under the auspices of the Utility Poultry Club are given.

Turkeys: Standard varieties and management, T. F. McGrew (*U. S. Dept. Agr., Farmers' Bul. 200, pp. 40, figs. 12*).—Among the questions discussed are the present condition of the turkey industry; standard varieties of turkeys; selection and treatment of breeding stock; egg laying, incubation, and hatching; care of young turkeys; feeding stock turkeys and feeding for market, marketing, parasites, and diseases.

"It should never be forgotten that in the wild state their food was the bugs, worms, seeds, etc., which they could find for themselves, and which were hunted for and scrambled after continually. There was then no overfeeding upon rich unnatural foods that impaired health and produced bowel troubles or other ailments that naturally follow unwholesome food. They subsisted by their own efforts in the wild state, while now they are quite too often forced to eat unnatural foods that are furnished in hope of forcing them to an unnatural growth."

Wet or sloppy foods are not recommended for young turkeys.

"Food should be given . . . [young turkeys] quite early in the morning and at frequent intervals during the day. Never overfeed them, but use discretion in providing plentifully for their necessities. Give them all they will eat willingly and no more. Avoid the use of rich foods, grains in hulls, and millet seed, which is not good for them while they are young; a little of this seed, however, may be fed as they grow older. Too much hard-boiled egg is bad for them, while a reasonable amount of bread is beneficial.

"Coarse sand is excellent for grit, and if sufficient of this is at hand no other grit will be needed; but plenty of grit of some kind is a necessity, for without it the poults can not grind their food."

Saturated limewater for the preservation of eggs, F. T. SHUTT (*Canada Expt. Farms Rpts. 1903, p. 261*).—Brief directions for the preservation of eggs in limewater, a method which the author states in his experience has proved more satisfactory than the use of water glass.

A new method of preserving eggs in use in Great Britain, L. IRWELL (*Dietet. and Hyg. Gaz., 20 (1904), No. 8, pp. 457, 458*).—The use of water glass for preserving eggs is described.

A cheap tick-proof fowl house for farmers, A. A. BROWN (*Jour. Dept. Agr. Victoria, 2 (1904), No. 8, pp. 757–760, figs. 7*).—Detailed directions are given for the construction of a hen house in such a manner as to prevent infestation from ticks either upon the roosts or nests.

DAIRY FARMING—DAIRYING.

Alfalfa hay, cowpea hay, and soy-bean silage as substitutes for purchased feeds; cotton-seed meal v. wheat bran and dried brewers' grains, C. B. LANE (*New Jersey Stas. Bul. 174, pp. 24*).—Home-grown products were compared with purchased feeds in 3 feeding experiments with cows. Each experiment included 4 cows and covered 2 periods of 15 days, the third experiment being duplicated. Tabulated data are given showing the yield and composition of milk and the cost of production.

In the first experiment a ration consisting of 17 lbs. of cowpea hay and 36 lbs. of corn silage, and containing 3.6 lbs. of protein with a nutritive ratio of 1:6, was compared with a ration consisting of 4 lbs. of wheat bran, 3 lbs. of dried brewers' grains, 2 lbs. of cotton-seed meal, 5 lbs. of cornstalks, and 36 lbs. of corn silage and containing 3.2 lbs. of protein with a nutritive ratio of 1:5.

The average daily yield per cow was 23.7 lbs. of milk, containing 3.86 per cent of fat, on the cowpea-hay ration, and 25.7 lbs. of milk, containing 4.11 per cent of fat, on the feed ration. The feed ration produced 8.3 per cent more milk and 15.2 per cent more butter than the cowpea-hay ration. The cost of producing 100 lbs. of milk and 1 lb. of butter was, respectively, 39.8 and 8.82 cts. when the cowpea-hay ration was fed, and 60.5 and 12.6 cts. when the other ration was fed.

The increased yield from feeding grain was not sufficient in this experiment to pay for the additional cost of the ration. Applying these results to a herd of 30 cows it is estimated that the gain from feeding the cowpea-hay ration would amount to $37.20 per month. "However, it is believed that a combination of coarse and fine feeds is necessary to produce the best results."

In the second experiment the home-grown ration consisted of 36 lbs. of soy-bean silage, 8 lbs. of alfalfa hay, and 6 lbs. of corn meal, and contained 3.64 lbs. of protein with a nutritive ratio of 1:5; and the feed ration consisted of 4 lbs. of wheat bran, 4 lbs. of dried brewers' grains, 2 lbs. of cotton-seed meal, 6 lbs. of cornstalks, and 36 lbs. of corn silage, and contained 3.45 lbs. of protein with a nutritive ratio of 1:6.

The average daily yield per cow was 27.2 lbs. of milk, containing 3.60 per cent of fat, on the home-grown ration, and on the purchased ration 25.7 lbs. of milk, containing 3.80 per cent of fat. The yield of milk on the home-grown ration was 5.81 per cent greater than that on the purchased ration, while there was practically no difference in the yield of butter.

These results are believed to show that it is practicable, from the standpoint of milk and butter production, to grow the entire ration upon the farm. At market prices the cost of producing 100 lbs. of milk and 1 lb. of butter on the home-grown ration was, respectively, 56.5 and 13.5 cts., and on the purchased ration, 65 and 14.6 cts., showing a considerable saving in the cost of milk and butter production when home-grown feeding stuffs were used.

In the third experiment a ration consisting of 4.5 lbs. of cotton-seed meal, 36 lbs. of corn silage, and 6 lbs. of cornstalks, and containing 2.97 lbs. of protein with a

nutritive ratio of 1:5.1, was compared with a ration consisting of 5 lbs. of wheat bran, 5 lbs. of dried brewers' grains, 36 lbs. of corn silage, and 6 lbs. of cornstalks, and containing 2.94 lbs. of protein with a nutritive ratio of 1:6.7.

The results of the 2 tests with 2 different lots of cows showed an average daily yield per cow of 22.7 lbs. of milk, containing 4.23 per cent of fat, on the cotton-seed meal ration; and 23.9 lbs. of milk, containing 3.98 per cent of fat, on the contrasted ration. While the yield of milk and butter was practically the same on the 2 rations, the cost of production was 54.1 cts. for 100 lbs. of milk and 11 cts. for 1 lb. of butter on the cotton-seed meal ration, as compared with 66 and 14.3 cts., respectively, on the contrasted ration. Applying these results to a herd of 30 cows, the gain per month from feeding cotton-seed meal, as compared with the bran and brewers' grains, would amount to $42.60. When cotton-seed meal is thoroughly mixed with corn silage or other starchy foods it is believed that it can be fed to the extent of 4.5 lbs. daily per cow without injurious effects.

Feeding dairy cows, W. J. Fraser (*Illinois Sta. Circ. 75, pp. 18*).—This circular treats in a popular manner of the nutrients in feeding stuffs, and the calculation of rations for dairy cows.

Dairy herd records, J. H. Grisdale and R. Robertson (*Canada Expt. Farms Rpts. 1903, pp. 59–67, 284–286, pl. 1*).—Detailed and summarized records are given of 38 cows of different breeds at the Central Experimental Farm, and of 20 cows at the Experimental Farm for the Maritime Provinces. Notes are also given on the feeding of the cows.

Improvement of dairy herds, H. A. Hopper (*Illinois Sta. Circ. 76, pp. 15, figs. 3, dgm. 1*).—This circular emphasizes the necessity of testing cows as a means of improving dairy herds. Directions are given for making tests and keeping records. Records of 2 cows are given for the purpose of illustrating the calculation of the yield of fat and the determination of the profit or loss. Brief notes are also given on the improvement of the herd by breeding and selection.

The effect of drinking water on milk secretions, Koch (*Jahresber. Pharm., 36; abs. in Wchnschr. Tierheilk. u. Viehzucht, 47 (1903), No. 29; Ztschr. Fleisch- und Milchhyg., 14 (1904), No. 8, p. 278*).

The transformation of food fat into milk fat, S. Gogitidse (*Ztschr. Biol., 45 (1904), No. 4, pp. 353–371, dgms. 2*).

The protein content of mother's milk, E. Meyer (*Dissertation, Berlin, 1902; abs. in Ztschr. Diätet. u. Phys. Ther., 7 (1903), No. 12, p. 697*).

Additional work upon the associative action of bacteria in the souring of milk and in other milk fermentations, C. E. Marshall (*Michigan Sta. Spec. Bul. 29, pp. 7*).—In an earlier article (E. S. R., 15, p. 1113) the author reported the results of experiments which showed that a micro-organism capable of peptonizing casein and rendering milk alkaline, materially hastened the curdling of milk when inoculated with a species of lactic-acid bacteria. Further experiments with these two micro-organisms, designated respectively micro-organism B and micro-organism A, are reported in this bulletin. Other species have also been found which hasten the curdling of milk, and still others which retard the process.

So far as the investigations have gone, the group which hastens curdling seems to predominate. Micro-organism B was found to die out within 50 hours when associated with the lactic-acid bacteria. The stimulating influence of this micro-organism was, therefore, exerted early in the process of development. To determine the nature of this stimulating influence micro-organism B was cultivated in milk for 48 hours, when the culture was sterilized. It was found that the products of micro-organism B were unchanged by sterilization and were as active in stimulating the lactic-acid bacteria as the living organisms themselves. Whey-agar made from a milk culture of micro-organism B was much more favorable to the growth of micro-organism A than whey-agar made from fresh milk.

In further experiments 100 cc. of milk was placed in each of 8 flasks, which were then sterilized on 3 consecutive days. Four of the flasks were inoculated with the same quantities of micro-organism B, and after 48 hours were again sterilized. The 8 flasks were then inoculated with a culture of micro-organism A, great care being taken to secure practically the same number of micro-organisms in each flask. The 4 flasks which had been inoculated with micro-organism B gave very uniform results, as did also the 4 flasks not inoculated with this micro-organism. Between the 2 sets, however, there was marked variation. The acidity developed much more rapidly in the first instance. At the end of 24 hours the number of bacteria in the flasks without the influence of micro-organism B was 12,920,000 per cubic centimeter, and in the flasks previously inoculated with micro-organism B, 517,920,000.

Micro-organism B, therefore, exerts an influence upon the development of micro-organism A as is shown by the visible changes brought about in the milk, by a study of the development of acid, and by determinations of the number of bacteria present. The results indicated that this influence is due to the products of micro-organism B. The work is believed to have a direct bearing on the subject of pure-milk supply, and is to be continued.

The cream separator on western farms, E. H. Webster and C. E. Gray (*U. S. Dept. Agr., Farmers' Bul. 201, pp. 24*).—This is condensed from Bulletin 59 of the Bureau of Animal Industry, previously noted (E. S. R., 16, p. 194).

The cream-gathering creamery, H. H. Dean and J. A. McFeeters (*Ontario Agr. Col. and Expt. Farm Bul. 135, pp. 12*).—This is a popular bulletin discussing and making suggestions on the selection and feeding of cows, creaming of milk, cream testing, delivering cream, oil tests, pasteurization, churning, and creamery building and machinery.

VETERINARY SCIENCE AND PRACTICE.

Report of the colonial veterinary surgeon for 1902 (*Cape Town: Govt. Printer, 1903; pp. 28*).—An outbreak of rinderpest occurred in Basutoland for the first time in 2 years. Attention is called to the necessity of thorough destruction of all centers of infection for this disease. Both bile and serum are used in preventive inoculation against the disease in Cape Colony. The chief advantage in favor of bile is the fact that it can be prepared with less skill and more quickly than serum. Serum is more effective, however, and cheaper. Notes are also given on pleuro-pneumonia, tuberculosis, inspection of dairies and abattoirs. Reports from the assistant veterinary surgeons are also presented.

Abattoirs and meat inspection in Holland, Kühnau (*Berlin. Tierärztl. Wchnschr., 1904, No. 37, pp. 625–630*).—The organization and execution of meat inspection in Holland are briefly described with notes on their different abattoirs. Statistics are presented on the number of animals inspected and on the precentage of animals found to be affected with tuberculosis, trichina, and other diseases.

Diseases of domestic animals (*Japan in the Beginning of the 20th Century. Tokyo: Imperial Japanese Commission to the Louisiana Purchase Exposition, 1904, pp. 196–199*).—A brief review is presented of the origin of animal diseases in Japan with especial reference to cattle plague, anthrax, glanders, black leg, pseudo-farcy, foot-and-mouth disease, and rabies. The status of veterinary practice is also briefly discussed.

A brief report of veterinary literature concerning wounds for the year 1901-2, E. Bass (*Deut. Tierärztl. Wchnschr., 12 (1904), No. 37, pp. 368–371*).—The literature of this subject is critically discussed in connection with a bibliography of 51 titles.

A brief report on the most important Italian literature in the field of general pathology and pathological anatomy for the year 1903, O. Barbacci (*Centbl. Allg. Path. u. Path. Anat., 15 (1904), No. 16–17, pp. 671–713*).—This report

contains a brief review of a large number of Italian books, pamphlets, and periodical articles on general pathology classified in 17 sections according to the parts of the body affected by different diseases.

Does the virus of ovine contagious agalactia pass through filters? A. CELLI and D. DE BLASI (*Clin. Vet., 27 (1904), No. 22, pp. 129–133*).—A series of inoculation tests with the virus of this disease as obtained from sheep and goats convinced the authors that the virus retains its virulence after being passed through filters.

Internal mycoses, E. BODIN and P. SAVOURÉ (*Arch. Parasit., 8 (1904), No. 1, pp. 110–136, figs. 9*).—Series of inoculations were made in experimental animals with *Rhizomucor parasiticus, Rhizopus equinus, Mucor corymbifer, Aspergillus fumigatus, A. niger*, and *Sterigmatocystis pseudonigra*. After inoculation the blood, peritoneal fluid, and various organs were examined for the purpose of detecting any hyperleucocytosis or other effect of the fungus organisms.

It was found that when fungus spores were inoculated into guinea pigs, the leucocytes surrounded the spores and entirely destroyed them in the case of nonpathogenic species, while in pathogenic species the spores produce local alterations when arrested in passing through the capillaries. Pathogenic spores, although surrounded by phagocytes, are not digested but remain intact and finally germinate. The digestion of nonpathogenic spores takes place in the macrophages or endothelial cells. Immunity toward infection with mold fungi therefore depends on destruction of the spores by macrophages. In these cases the theory of Metchnikoff seems to be sustained.

Mycoses in the respiratory passages, P. LESAGE (*Arch. Parasit., 8 (1904), No. 3, pp. 353–443, figs. 14*).—A long series of observations and experiments were made to determine the moisture content of respired air in man and animals, and the effect of contact with the walls of the respiratory passages on the germination of fungus spores, particularly *Sterigmatocystis nigra*.

It was found that spores placed on the tracheal or bronchial walls of birds or man either do not germinate at all or more slowly than in air saturated with water vapor and at the body temperature. The normal hygrometric conditions of the respiratory passages appear to have a marked effect on the germination of spores, and this fact must be considered in a study of mycoses in animals or man.

Rats, mice, and their parasites in their relation to the distribution of bubonic plague, C. TIRABOSCHI (*Arch. Parasit., 8 (1904), No. 2, pp. 161–349, figs. 72*).—A general account is presented of the rats and mice of Italy, with notes on the species and their distribution. Descriptive biological and economic notes are also given on the numerous species of fleas, lice, and mites which are known to live as parasites on rats and mice. The evidence regarding the agency of these parasites in carrying plague is not conclusive in any case.

A new saccharomycosis in rabbits, H. ROGER and P. E. WEIL (*Arch. Méd. Expér. et Anat. Path., Paris, 16 (1904), No. 2, pp. 145–162, pls. 2, fig. 1*).—During the course of the authors' experiments, 31 rabbits were inoculated with cultures of *Saccharomyces linguæ pilosæ*. The lesions thus produced varied according to the method of inoculation. The chief alterations were in the kidneys, while the liver was affected in only a part of the cases. It was found possible to immunize rabbits by vaccinating them with the fluid in which the yeast fungus was grown. The organism is easily removed by filtration on account of its large size.

Concerning metabolism in convalescing animals, SCHWENKE (*Arch. Exper. Path. u. Pharmakol., 48 (1902), p. 170; abs. in Ztschr. Diätet. u. Phys. Ther., 7 (1904), No. 9, p. 516*).—Experiments with dogs are reported and discussed.

Further studies on dourine, J. MAREK (*Ztschr. Thiermed., 8 (1904), Nos. 1–2, pp. 11–23; 3–4, pp. 161–178, figs. 3*).—Detailed notes are furnished on the histological structure of lesions of this disease in various tissues, such as the intervertebral ganglia, extraspinal tissues of the spinal nerves, muscles, and sexual organs.

In nearly all affected muscle tissue there were groups of round cells embracing the blood vessels. The peripheral nerves were affected with cellular infiltration and disintegration or disappearance of the nerve fibrils. Cellular infiltration was observed also in the spinal cord and other parts of the nervous system. The intraspinal motor nerve roots, with the exception of the first sacral nerve, showed no fibrillar degeneration. The sensory roots, however, showed pronounced degeneration. Cell infiltration was observed in the dura mater surrounding the proximal portion of both the motor and sensory roots.

Laryngo-tracheobronchitis and its complications, I. N. POTAPENKO (*Arch. Vet. Nauk., St. Petersburg, 34 (1904), No. 5, pp. 381–419*).—Clinical notes are given on the history of numerous cases of this disease in horses. Data are presented also to assist in rendering a differential diagnosis between this and other related diseases.

Vaccination of herbivora for rabies, P. REMLINGER and M. EFFENDI (*Rec. Méd. Vét., 81 (1904), No. 9, pp. 289–298*).—In 1903 12 cattle and 10 buffalo were vaccinated with poor results, 63 per cent of the animals dying of rabies. Detailed notes are given on these cases and also on the vaccination of 8 horses with a loss of 62 per cent as a result. The authors believe that vaccination should be repeated frequently as in man. The intravenous method is also suggested in order to obtain more satisfactory results.

Experimental cirrhosis of the liver, WERA DANTSCHAKOFF-GRIGOREVSKY (*Centbl. Allg. Path. u. Path. Anat., 15 (1904), No. 16–17, pp. 667–670, figs. 2*).—Cirrhosis of the liver was artificially produced in rabbits by a systematic inoculation of cultures of staphylococci. The cultures selected for this purpose were of low virulence, and the rabbits received from 1 to 2 cc. for their first injection. Each experimental animal received from 30 to 105 cc. in all. The pathological changes produced in the rabbits were similar in all cases. A detailed description is given of these changes both as regards the external appearance of the liver and the microscopic character of the affected liver tissue.

Preliminary report on the international tuberculosis conference at Copenhagen, May 26–29, 1904 (*Tuberculosis, 3 (1904), No. 8, Sup., pp. 162*).—The papers read at this conference are presented in a slightly condensed form, in German, French, and English. The problems discussed involved all of the various aspects of tuberculosis of animals and man with especial reference to the legal, sanitary, and curative measures which have recently been recommended and tested in controlling this disease.

A lesson in bovine tuberculosis, H. L. RUSSELL (*Wisconsin Sta. Bul. 114, pp. 8, fig. 1*).—Attention is called to the extensive and insidious spread of tuberculosis among dairy herds. As an example of the distribution of the disease the author outlines the history of a herd of 46 cattle which was sold to 12 different persons and of which 32 animals were later found to be tuberculous. Fortunately the tuberculous infection was discovered in most instances before the disease had spread to other animals. This, however, is a good illustration of the necessity of applying the tuberculin test before buying cattle for introduction into the home herd.

Bovine and human tuberculosis, P. BESSE (*Arch. Méd. Expér. et Anat. Path., Paris, 16 (1904), No. 3, pp. 375–387, figs. 5*).—The various forms of human and bovine tuberculosis are described. Three cases of pearl disease, or serous tuberculosis, in man are described, and attention is called to the identity of the lesions with those in cattle. In 2 of these 3 cases there was good evidence that the primary infection took place through the walls of the alimentary tract. The identity of bovine and human tuberculosis is considered unquestionable.

Are the human and bovine forms of tuberculosis due to one bacillus? J. LIGNIÈRES (*Bul. Soc. Cent. Méd. Vét., 81 (1904), No. 8, pp. 241–247*).—All tubercle bacilli belong to the same group, but may be readily classified into distinct varieties which differ in cultural and pathogenic characters. The bovine, avian, and human

types may be distinguished, and as a rule these types are found in the corresponding animal organisms. Occasionally, however, tubercle bacilli of the bovine type are found in cases of intestinal tuberculosis in man. The disease is believed to be easily transmissible from animals to man.

Tuberculosis, the chief defect in slaughtered animals, MALKMUS (*Deut. Tierärztl. Wchnschr., 12 (1904), No. 13, pp. 122–124*).—Attention is called to the provisions of the German meat-inspection laws regarding the procedure with the meat of tuberculous animals. Such meat is not considered as dangerous for food except in cases of generalized tuberculosis.

Inoculation of dogs with human tuberculosis, LEUDET and G. PETIT (*Rec. Méd. Vét., 81 (1904), No. 9, pp. 298–303*).—In one series of experiments it was found that quite uncertain results were obtained by spraying diluted virulent cultures of human tubercle bacilli into the respiratory passages of dogs by means of an atomizer. Dogs were easily infected by means of intravenous or intrapleural inoculation or through the alimentary tract. The authors believe therefore that dogs may become agents in the distribution of tuberculosis.

Mammary tuberculosis, L. NATTAN-LARRIER (*Arch. Méd. Expér. et Anat. Path., Paris, 16 (1904), No. 2, pp. 177–190, pl. 1, figs. 2*).—Suspected pathological fluids were tested by inoculating guinea pigs in the mammary glands. A histological study of the milk was then made from day to day. The results obtained by this method are critically discussed. The method is recommended especially for the study of tuberculous pus and cephalorachidial fluid. The rapidity and accuracy of the method are quite satisfactory. It is considered of equal value with the subcutaneous method, but inferior to intraperitoneal inoculation.

Tuberculin (*Clin. Vet., 27 (1904), No. 2, pp. 1–8*).—A brief discussion of the action and value of tuberculin. The conclusion is reached that tuberculin is nearly an infallible test.

Ringworm on cattle (*Jour. Dept. Agr. and Tech. Instr. Ireland, 4 (1904), No. 4, pp. 705, 706*).—Affected areas of skin may be successfully cured by treating repeatedly at intervals at 2 or 3 days with a mixture containing 1 pt. of fish oil per ½ lb. of sulphur.

Hematuria of cattle, MOUSSU (*Bul. Soc. Cent. Méd. Vét., 81 (1904), No. 8, pp. 222–227*).—A controversial article on the means of transmission of this disease.

Variations in the size of beef cystocerci, KÄPPEL (*Deut. Tierärztl. Wchnschr., 12 (1904), No. 15, p. 143*).—A number of measurements were made of cysticerci of different ages and the results are presented in tabular form.

The treatment of contagious vaginitis, ESTOR (*Deut. Tierärztl. Wchnschr., 12 (1904), No. 27, pp. 265–267*).—Vaginitis is believed to be responsible for many cases of sterility in cows. Good results were obtained by the author from the internal application of chinosol mixed with a bland oil.

Milk fever before calving, A. HÖIJER (*Finsk Veterinärtidskr., 10 (1904), No. 2, pp. 48, 49*).—A brief discussion is presented of the occurrence of this disease before parturition. In one case excellent results were obtained from the application of the air treatment. A normal parturition took place without help on the day following the administration of air, and the cow made complete recovery.

Cases of puerperal eclampsia before calving, H. V. HELANDER (*Finsk Veterinärtidskr., 10 (1904), No. 2, pp. 46, 47*).—Two cows which developed milk fever just previous to calving were treated with injections of potassium iodid without success, death resulting in both cases. With a third cow with similar history the air treatment was adopted, with the result that great improvement took place within a few hours and complete recovery after a few days.

Husk or hoose in calves (*Jour. Dept. Agr. and Tech. Instr. Ireland, 4 (1904), No. 4, pp. 703, 704*).—The symptoms and etiology of this disease are briefly described. In combating the trouble, it is recommended that calves be not allowed to graze on

marshy ground and that each affected calf be given daily 1½ tablespoonfuls of a mixture containing 1 dr. oil of cloves, 3 oz. spirits of turpentine, and 24 oz. linseed oil.

Prevention of white scour in calves (*Natal Agr. Jour. and Min. Rec., 7 (1904), No. 6, p. 540*).—In treating this disease it was found necessary to disinfect the premises as well as navel of new born calves.

The sheep nostril fly (*Jour. Bd. Agr. [London], 11 (1904), No. 4, pp. 227–230, figs. 7*).—Notes are given on the habits and means of combating *Oestrus ovis*. Treatment of the nostrils with deterrents and isolation of infested sheep are recommended in controlling this pest.

Experiments on artificially diminishing the metabolism of protein in a sheep with fever, S. WEBER (*Arch. Exper. Path. u. Pharmakol. (1902), pp. 19–47; abs. in Ztschr. Diätet. u. Phys. Ther., 7 (1904), No. 12, pp. 696, 697*).

A clinical and bacteriological study of swine plague, T. GUERRIERI (*Clin. Vet., 27 (1904), No. 14, pp. 81–84*).—Distinction is made from a clinical and bacteriological standpoint between swine erysipelas, hog cholera, and swine plague.

Pyroplasmosis in the horse, C. S. DE LA CALZADA (*Gac. Med. Zool., 28 (1904), No. 2, pp. 19–25*).—This disease is also known under the name equine malaria. The blood parasite is described and notes are given on the symptoms, etiology, and treatment of the disease.

The leucocytes of the blood of the horse, and certain experimental leucocytoses, C. BIDAULT (*Arch. Méd. Expér. et Anat. Path., Paris, 16 (1904), No. 2, pp. 355–374, figs. 6*).—The different kinds of leucocytes are carefully described and notes are given on the technique of their examination. According to counts made by the author, the number of leucocytes in the healthy horse varies from 10,000 to 11,000 per cubic centimeter. The relative proportions of the various kinds of leucocytes are also indicated. Pilocarpin increased the number of polynuclear and eosinophilous cells, while iodid of potash affected the mononuclear cells. Antitetanus serum caused a marked polynucleosis and similar effects were observed after hypodermic injections of mallein. A hyperleucocytosis was always produced in healthy horses by mallein.

A North African trypanosome, RENNES (*Bul. Soc. Cent. Méd. Vét., 81 (1904), No. 8, pp. 248–250*).—Brief notes are given on the symptoms and etiology of a horse disease known as zousfana, and differing from dourine. The symptoms in horses closely resemble those of sleeping sickness in man.

Poisoning of horses from eating the plant Ornithogalum thyrsoides, D. HUTCHEON (*Agr. Jour. Cape Good Hope, 25 (1904), No. 1, pp. 48–50*).—Horses were killed by eating this plant. Feeding experiments showed that 3 lbs. of the green plant were sufficient to cause death with symptoms of great depression and acute gastro-enteritis.

Abortion of mares, R. E. WEIR (*Jour. Dept. Agr. West Australia, 9 (1904), No. 3, p. 143*).—Brief notes are presented on the causes and treatment of this disease. Antiseptic treatment with corrosive sublimate is recommended.

Two cases of tetanus cured by subcutaneous injections of carbolic acid, G. CROCE (*Clin. Vet., 27 (1904), No. 11, pp. 61–64*).—In one case in a horse a cure was effected by 4 injections of 10 gm. each of a mixture containing 1 gm. carbolic acid per 100 gm. glycerin. In a second case, with more alarming symptoms, much larger doses were given with satisfactory results.

Some experiments with Soberheim's anthrax serum, A. HÖIJER (*Finsk Veterinärtidskr., 10 (1904), No. 3, pp. 68–74*).—A brief review is presented regarding the results obtained from the use of this serum in treating anthrax in horses and other animals. It was found that this serum possesses considerable bactericidal power toward the anthrax bacillus.

Notes from practice, O. NOACK (*Deut. Tierärztl. Wchnschr., 12 (1904), No. 25, pp. 247, 248*).—The author reports poor results from the use of antitoxin in the treat-

ment of tetanus. Better success was had with injections of carbolic acid and glycerin. Recovery took place in 6 out of 9 cases in horses and mules. Milk fever was rapidly cured in 8 cases by infusions of oxygen or atmospheric air.

A historical account of anthrax vaccination in the government of Kherson (1882–1903), A. Nitzkevich (*Arch. Vet. Nauk, St. Petersburg, 34 (1903), No. 5, pp. 421–443*).—A general account of vaccination against anthrax as used in the Kherson Government of Russia, with notes on the rate of mortality after vaccination.

Treatment of rabies in dogs, S. V. Obukhov (*Arch. Vet. Nauk, St. Petersburg, 34 (1904), No. 5, pp. 419, 420*).—Brief notes on the symptoms and treatment of this disease.

Preliminary report on the treatment of persons bitten by mad wolves, V. Babes (*Ztschr. Diätet. u. Phys. Ther., 8 (1904) No. 1, pp. 3–12*).

A serious turkey disease, M. Grinnell (*Reliable Poultry Jour., 11 (1904), No. 5, pp. 559 560*).—Experiments with blackhead are reported.

AGRICULTURAL ENGINEERING.

A report on irrigation conditions in the Yakima Valley, Washington, O. L. Waller (*Washington Sta. Bul. 61, pp. 29*).—An account of studies made in cooperation with the Irrigation Investigations of this Office of the water supply of the Yakima and Natches river systems, the amounts of water claimed and used, measurement and distribution, duty of water, the value of land and water, seepage losses and drainage, and legal and administrative problems. Recommendations are made regarding needed legislation and the organization of an administrative system.

Irrigation in Siam, J. H. van der Heide (*Bul. Écon., Dir. Agr. et Com. Indo-China, n. ser., 7 (1904), No. 29, pp. 490–524, map 1*).—This report discusses in detail the possibilities of irrigation and the need of drainage in the lower Valley of Menam, and describes a plan for extending the present system of irrigation for rice to cover an area more than half the size of all the lands now actually in cultivation in Siam. It is claimed that the proposed system will more than double the yield of rice and greatly increase and facilitate internal navigation.

The irrigation of the Chentu Plateau, A. Little (*Scottish Geogr. Mag., 20 (1904), No. 8, pp. 393–403, pls. 2, figs. 5*).—This is an extract from a book by this author on The Far East, and describes the elaborate system of irrigation which has been followed from time immemorial on this very fertile and densely populated plain, which has an area of 2,400 square miles.

Treatment of a reservoir of the Butte Water Co. with copper sulphate, E. Carroll (*Engineer. News, 52 (1904), No. 7, pp. 141–143, figs. 2*).—The treatment by the method recommended by Moore and Kellerman of this Department is said to have proved "harmless, cheap, and effective."

On artificial underground water, K. A. Widegren (*Natal Agr. Jour. and Min. Rec., 7 (1904), No. 7, pp. 682–690*).—A summary of previous articles by the author noted elsewhere (E. S. R., 15, p. 622).

River Improvement and Drainage Association of California (*River Imp. and Drainage Assoc. California Bul. 1, pp. 8*).—A brief account of the organization of this association.

Methods of estimating stream flow, J. C. Hoyt (*Engineer. News, 52 (1904), No. 5, pp. 104, 105, figs. 4*).—Methods commonly used are described.

Preliminary report on the building stones of Nevada, including a brief chapter on road metal (*Univ. Nevada, Bul. Dept. Geol. and Min., 1 (1904), No. 1, pp. 63, pl. 1*).—This is a preliminary report which discusses the main principles governing the selection and use of building stones and road metal, and describes

briefly the stones now in use or which can easily be obtained in Nevada, with their location and availability.

Historic highways of America, A. B. HULBERT (*Cleveland, Ohio: Arthur H. Clark Co., 1904, vol. 12, pp. 202, maps 3*).—This volume deals with the pioneer roads and the experiences of travelers. For notice of previous volumes of this series see E. S. R., 15, pp. 415, 1135.

On the durability of American swing plows, E. JÖRGENSEN (*Tidsskr. Landökon., 1904, No. 2, pp. 137–145*).

Trials with preservatives for plows, E. JÖRGENSEN (*Tidsskr. Landökon., 1904, No. 6, pp. 311–313*).—A mixture of 1 part chalk and 2 parts tallow, applied hot, was found effective as a preservative for the iron parts of plows.—F. W. WOLL.

Trials with Korsgård's potato harvester, E. JÖRGENSEN (*Tidsskr. Landökon., 1904, No. 6, pp. 307–310*).

Trials with reapers and mowers, E. JÖRGENSEN (*Tidsskr. Landökon., 1904, No. 2, pp. 146–158*).

Trials of agricultural machinery in Denmark during 1903, E. JÖRGENSEN (*Tidsskr. Landökon., 1904, No. 2, pp. 117–136*).

Agricultural motors, G. COUPAN (*Les moteurs agricoles. Paris: J. B. Baillière & Sons, 1904, pp. 484, figs. 269; rev. in Jour. Agr. Prat., n. ser., 7 (1904), No. 16, pp. 524, 525; Rev. Sci. [Paris], 5. ser., 2 (1904), No. 7, pp. 49–51*).—This treatise forms one volume of *Encyclopédie agricole*, published under the direction of G. Wery. The detailed account of the various agricultural motors which are grouped in four classes—animal motors, vapor motors, explosion motors, and miscellaneous (wind, water, and electric), is preceded by a discussion of general mechanical principles.

Round cotton bales, D. A. WILLEY (*Amer. Inventor, 12 (1904), No. 9, pp. 198, 199, figs. 5*).

MISCELLANEOUS.

Seventeenth Annual Report of Maryland Station, 1904 (*Maryland Sta. Rpt. 1904, pp. XVI+104*).—This contains a brief outline of the work of the station during the year by the director; the organization list, a financial statement for the fiscal year ended June 30, 1904, and reprints of station bulletins 90–92, on the following subjects: Experiments on the control of the San José scale (E. S. R., 15, p. 978), experiments with nitrogenous fertilizers (E. S. R., 16, p. 138), and notes on apple culture (E. S. R., 16, p. 156).

Eleventh Annual Report of Minnesota Station, 1903 (*Minnesota Sta. Rpt. 1903, pp. 280*).—This includes the organization list of the station; a report of the director containing a financial statement for the fiscal year ended June 30, 1903, and a review of the different lines of station work; and reprints of Bulletins 77–82 of the station on the following subjects: Insects notably injurious in 1902 (E. S. R., 14, p. 779); experiments in sheep husbandry (E. S. R., 14, p. 994); investigation in milk production (E. S. R., 14, p. 1003); alfalfa, its chemical development, feeding value and digestibility, and the digestibility of hog millet (E. S. R., 14, pp. 958, 992, 993); review of the work of the Northeast Experiment Farm since its organization in May, 1896 (E. S. R., 15, pp. 233, 236, 252, 260, 290); and hemorrhagic septicemia (E. S. R., 15, p. 514).

Abstracts showing the acreage under crops, and the number of live stock in each county and province for 1903–4 (*Dept. Agr. and Tech. Instr. Ireland, 1904, pp. 19*).—In this pamphlet statistics are presented in tabular form on the total acreage of various crops in Ireland indicating also the amount of decrease or increase over former years. Lists are also given showing the numbers of various kinds of live stock.

Agricultural returns, 1903 (*Bd. Agr. and Fisheries* [*London*], *Agr. Returns, 1903, pp. 33*).—Tables showing the total produce and yield per acre of the principal crops in each county of Great Britain, with summaries for the United Kingdom. Brief notes on the different crops are also given.

Agricultural statistics of Ireland with detailed report for the year 1903 (*Dept. Agr. and Tech. Instr. Ireland, 1904, pp. XXXIII+165*).—This report contains statistics on crop areas, crop production, land holdings, numbers of various kinds of live stock, forest areas, extent of beekeeping, and other statistical details of interest to farmers.

Notes on Egyptian agriculture, G. P. Foaden (*U. S. Dept. Agr., Bureau of Plant Industry Bul. 62, pp. 61, pls. 6, figs. 3*).—This bulletin discusses agricultural conditions in Egypt and lays special stress upon the culture of cotton and its importance to the country's export trade. Soils, irrigation, labor, value of land, and the seasons are considered and much statistical information is included.

In addition to cotton culture, which is described in detail, the bulletin also presents brief descriptions of the culture, value, and uses of sugar cane, sugar beets, berseem, alfalfa, corn, wheat, barley, rice, beans, onions, millets, sorghums, and a number of minor crops.

The fertilizer and rotation experiments with cotton reported here have been noted from another source (E. S. R., 14, p. 754).

Organization of the Bureau of Chemistry (*U. S. Dept. Agr., Bureau of Chemistry Circ. 14, pp. 15*).—This contains general statements concerning the organization and work, and a complete list of the publications of the Bureau.

Experiment Station Work, XXVI (*U. S. Dept. Agr., Farmers' Bul. 202, pp. 32, figs. 9*).—This number contains articles on the following subjects: Reclamation of flood-damaged lands, mulching vegetables and fruits, the cultivation of orchards, thinning apples, pop corn, fruit for farm animals, protein for dairy cows, cost of raising calves and pigs, manufacture of sage cheese, manufacture of cottage cheese, and a cheap fruit evaporator.

International catalogue of scientific literature. L—General Biology, H. W. M. Tims (*Internat. Cat. Sci. Lit., 2 (1903), pp. 120*).—As in previous numbers of this catalogue a general list of authors is presented followed by a subject catalogue in which the different publications are arranged alphabetically and with authors.

Hints on making nature collections in public and high schools, W. H. Muldrew (*Ontario Agr. Col. and Expt. Farm Bul. 134, pp. 23, figs. 20*).—The author briefly outlines certain desirable methods to be observed in collecting and preparing museum specimens of insects, birds' nests, and other objects in natural history for use in the public schools. A brief list of books bearing on this subject is also given.

NOTES.

Iowa College and Station.—A new dairy building, 110 by 60 feet, is in process of erection, and is expected to be ready about January 1, in time for the use of the dairy school. The building is of cream-colored brick with Bedford stone trimmings. The construction is fireproof, reinforced concrete being used. There are three stories, a basement, and a large attic. The walls of the corridors and workrooms have a wainscoting of enameled brick 5 feet high, with cream pressed brick above. The floors are largely concrete. The lockers and the refrigerating machinery are located in the basement. The building will cost, with equipment, from $55,000 to $60,000. Plans have been made for a new agricultural building to cost from $250,000 to $300,000. This building will have a frontage of 244 feet by a depth of 80 feet in the main part, with a central wing at the rear 70 by 80 feet. There will be three stories above a high-working basement, and an attic which may be used for some departments. On the second and third floors in the central wing there will be an assembly room, which will accommodate about 1,200 people. The building will accommodate the departments of agronomy, soils, agricultural chemistry, horticulture and forestry, and animal husbandry, and offices for the dean and director and for other experiment station purposes. For the present the domestic science department will occupy the top floor. The plans call for fireproof, steel construction, with stone exterior. The drawings of the building, displayed at the Des Moines convention, show a handsome and impressive structure. W. H. Ogilvie has been appointed station editor, and will have charge of the editing and proof reading of the bulletins and of the mailing list.

Kentucky Station.—W. G. Campbell, assistant in cooperative experiments, is no longer connected with the station.

Maine Station.—Edith M. Patch has been appointed entomologist to the station.

Missouri University and Station.—M. F. Miller, formerly of Ohio State University, is now in charge of the department of agronomy, with A. E. Grantham as assistant.

North Carolina Station.—Gordon M. Bentley has been appointed assistant entomologist in the State Department of Agriculture and the experiment station.

Pennsylvania Station.—N. C. Hammer, a graduate of the University of Virginia in the class of 1902, and A. W. Clark, a graduate of the University of Vermont in the class of 1904, have been appointed assistant chemists in the station. The United States Secretary of Agriculture has appointed F. W. Christensen assistant expert in animal nutrition, in conformity with the agreement recently made with the station, and assigned him to duty in connection with the cooperative experiments with the respiration calorimeter. R. E. Stallings, assistant in animal nutrition, will devote his entire time during the remainder of the year to the investigations with the respiration calorimeter. The dedication of the new library took place Nov. 18. The library is the gift of Mr. Andrew Carnegie. It is built of light-colored brick and stone and cost $150,000.

Porto Rico Station.—The annual report of this station for 1904, recently received, states that an effective hymenopterous parasite of the coffee-leaf miner (*Cemiostoma coffeella*) has been discovered and its habits and life history are being studied with the view of distributing the parasite to plantations in which its operation is not evident. Only

about 1 per cent of burrows in coffee leaves at the station contain living Cemiostoma larvæ, while evidence of larvæ or pupæ of the parasite is found in about 25 per cent of the leaves. A bacterial, or possibly fungus, disease of the Cemiostoma larvæ is also apparent; a large percentage of the burrows contain dead larvæ of all sizes. It is estimated that the leaf miner destroyed 5 to 10 per cent of the Island's coffee crop in 1903. Recent additions to the collection of bananas and plantains now growing on the station grounds bring the list up to about 65 named varieties. The Tanier (Xanthosoma) collection now contains over 40 named varieties. Over 20 kinds of yams (Dioscorea) are being tested.

Rhode Island College and Station.—The college, through its extension work, is planning to make special effort this fall and winter to increase its usefulness by sending members of its faculty to different parts of the State, where needed, to deliver lectures on various horticultural subjects. Matthew Steel, of New Mexico, recently scientific aid in the Office of Experiment Stations, has been appointed assistant chemist in the station.

Vermont University and Station.—The State legislature has appropriated $60,000 for the erection and equipment of an agricultural building, which has been greatly needed by the agricultural department of the university and the experiment station. It is planned to spend about $50,000 on the building, leaving $10,000 for the equipment of the offices, class rooms, and laboratories.

Virginia College and Station.—Laboratory equipment for studies in bacteriology, and for the preparation of cultures for the inoculation of various legumes has been ordered. Investigations along this line will be conducted by Dr. Meade Ferguson, bacteriologist of the station. Some important work has been undertaken by the veterinary department looking to the isolation of germs of a disease which has proved very destructive to some classes of live stock in this State. It is believed to be caused by a new and distinct organism. The station staff is cooperating with the State board of agriculture in holding institutes in various parts of the State. The college made an elaborate exhibit of live stock at the State Fair at Roanoke, and also at Radford. Representative herds of Shorthorn, Hereford, Aberdeen Angus, Holstein-Fresian, Jersey, and Guernsey were shown. Plans have been completed for a new cattle feeding barn, 100 ft. long and 40 ft. wide. This barn will be erected immediately, and will provide shelter for 100 head of cattle. It is designed especially for experimental purposes.

Arlington Experimental Farm.—An implement storage building 36 by 100 ft. and two stories high has been completed. The basement will be used for the cold storage of nursery stock and the second floor as a carpenter room. Attached to the same building is a boiler house 30 by 40 ft., which has just been completed. This will be the central heating plant for all of the buildings on the place. The foundations for two greenhouses, each 20 by 100 ft., have been laid. This is the beginning of a bank of about 10 houses which it is proposed to build.

Central Experiment Station of Cuba.—The staff of this station as at present organized is as follows: F. S. Earle, director; N. S. Mayo (formerly of the Kansas station), vice director and chief of the department of animal industry; C. F. Baker, chief of the department of botany; M. T Cook, chief of the department of plant pathology; F. Cruz, chief of the department of agriculture; and C. F. Austin (formerly of the Maryland station), chief of the department of horticulture. The chief of the department of chemistry has not yet been selected. In addition to the regular assistants, student assistants are also employed in the various departments. The station has no board of control, but is directly responsible to the Secretary of Agriculture. Dr. Mayo was present at the Des Moines meeting of the Association of American Agricultural Colleges and Experiment Stations, as a representative of the station, and expressed himself as much impressed with the opportunities for work of great usefulness. The grounds of the station are now being put in order, and chemical,

botanical, agronomical, and bacteriological laboratories are being fitted up. The station is reported to be receiving the cordial support of the Cuban Government and the people.

Normal Farmers' Institute in Pennsylvania.—A normal institute for farmers' institute workers, lecturers, and local managers was held at Bellefonte and State College, October 11–15, under the auspices of the State department of agriculture. There were about 135 in attendance. Lectures were delivered by college and station men on such subjects as soil improvement, animal nutrition, principles of plant breeding, principles of animal breeding, fruit culture, market gardening, breeding in relation to disease, potato culture, and the like; and a number of speakers from outside the State were present. Among the papers presented was one by John Hamilton, of this Office. One of the ways suggested by Professor Hamilton for increasing the supply of efficient institute lecturers, directors, and managers was by the establishment of interstate normal farmers' institutes. For this purpose a union of the States into groups of 6 to 8 each was suggested, the school to be held each year at different institutions within the group. The teaching force could be made up of specialists contributed by each institution, and the course of lectures be extended to cover a period of 4 to 8 weeks each session. A complete course of study would cover a period of at least 2 years, and certificates might be given to those who passed the examination in any of the courses offered. Classes could be organized on special subjects with specialists to teach them, and by the combination of the several States the increased attendance thus assured would be sufficient to practically pay for the expenses of the teaching force. It was believed that "such a set of schools properly equipped will do as much to assist farming people as any other single institution in existence, important as many of them are. . . . The organizing of interstate normal schools of agriculture for institute workers is the next great advance that the institute movement is destined to secure. When this is had, then the great need of the institute movement will be supplied—the need for means of equipping a large number of capable and enthusiastic men and women who will carry the news of a better agriculture to farming people." The proceedings of the meeting will be published.

Agricultural Instruction for Farmers in Victoria.—In a recent survey of the work and progress of the Victoria Department of Agriculture, the director for agriculture states that in order to better instruct farmers on agricultural matters, classes of instruction for farmers and farmers' sons, extending over several weeks, have been established in seven different centers. The results of two years' work along this line have been very satisfactory, and it is stated that this method of instruction has come to stay in Victoria and will extend over the whole of Australia. The winter season appears to be the only time when farmers can devote the daytime to lectures and study. In order to meet the demands for all classes during the winter months it has been found desirable to maintain a teaching staff for the whole year, since it is difficult to pick up suitable teachers just for the 3 or 4 months of the winter season. A plan has therefore been matured for keeping the force which it is proposed to thus engage in active service during the whole year. It is the purpose of the director to have evening classes of 2 weeks' duration held at farmhouses, where classes of from 10 to 12 may be organized. These classes will be held all the year around except in the winter time, when the officers will be engaged at the farmers' day classes, according to the present plan of operation. The proposed plan is outlined as follows: "The lectures would be held in the evening, say one and a half hours' lecture and a half hour devoted to asking and answering questions. Four lecturers would be required, one of whom would arrive on a Monday and stay 3 days lecturing and discussing such subjects as manuring suitable to the district, tillage, rotation of crops, and kindred subjects. On the fourth day he would leave for another center, say 20 miles away, and would be replaced by an officer competent to lecture on farm stock,

their breeding and management. In 2 days the second lecturer would leave, being replaced by a third who might lecture upon poultry, the best breeds to be kept for export and laying purposes, the management and feeding of poultry, etc. Two days later this lecturer would be replaced by a fourth, who would lecture on other agricultural subjects. The course of instruction at this particular farmhouse would then terminate after 10 days' instruction. Four classes would be in progress at one time in farmhouses sufficiently far apart to prevent overlapping, and yet near enough for the officer to reach the next center and lecture on the same day."

Agriculture at the British Association.—At the recent meeting of the British Association Dr. Wm. Somerville made the opening address as chairman of the subsection on agriculture. The address covered such subjects as the "fæcal excretions" of plants, the stimulating and exhausting effects of manures, German investigations on the action of conserving agents on farmyard manure, chemical fixation of atmospheric nitrogen, Nitragin, improvement of varieties of crops, and cooperative work. The result of German investigations in the preservation of stable manure were said to indicate no preservative effect but rather a loss of nitrogen by the use of such agents as kainit, superphosphate, precipitated phosphatic gypsum, and gypsum. It appears that superphosphate may conserve nitrogen to an appreciable extent so long as the manure lies in the stall, but its effects disappear whenever its acid phosphate and free sulphuric acid are neutralized by ammonia, and this rapidly occurs in the pit. Sulphuric acid sprinkled over manure as it was placed daily in the pit reduced the loss of nitrogen from 27.8 to 7.1 per cent, but the cost for this preservative was excessive, and its use is associated with so many drawbacks that its employment can not be recommended. The general conclusion appears to be that the excessive loss of nitrogen in manure can be best avoided by storing it in a deep compact mass in a water-tight pit in a well-shaded situation. Dr. Somerville pointed out that in field experiments with calcium cyanamid results about 20 per cent below those obtained by the use of an equal amount of nitrogen in the form of sulphate of ammonia have been obtained, while in pot cultures much better results were secured than either with nitrate of soda or sulphate of ammonia. It is thought that possibly root acids in the soil may partly change the calcium cyanamid into the dicyanamid, a substance directly poisonous to plants. A review of the present status of Nitragin shows a renewed interest in this matter both in Germany and in the United States. Previous "failure of the Nitragin to effect an improvement in the crop when it was sprinkled on the seed is now believed to be due to the action of secretions produced by the seed in the early stages of germination." The present indication was said to be that this difficulty may be obviated by cultivating the bacteria in a medium that imparts to them the necessary power of resistance. In speaking of the improvement of crops by selection, some striking figures were given showing the differences in growth of spruce trees from seed selected from mother trees varying considerably in dimensions and situated at various altitudes. In general the seedlings follow closely after the mother trees in rapidity and manner of development.

Miscellaneous.—A pamphlet of 15 pages, entitled A Tribute to Levi Stockbridge, by William H. Bowker, a former student and of late years a member of the board of trustees of the Massachusetts Agricultural College, has been received. The paper was read at the memorial exercises held for Professor Stockbridge at the college last commencement, and contains many interesting personal recollections, as well as a tribute to Professor Stockbridge as a teacher and in making practical application of scientific truth to agriculture.

A recent pamphlet entitled Obituary Notices of Fellows of the Royal Society, part 3, contains notes by "R. W." on Sir John Bennett Lawes and Sir Joseph Henry Gilbert, and on the agricultural investigations conducted jointly by these two men. These notices are especially interesting, as they were written by one who had an

inside view of the work at Rothamsted and an unusually intimate knowledge of the men. With reference to their joint work the writer says:

The government of the Federated Malay States has, according to a note in *Nature*, decided to establish an agricultural department in Malay, and has appointed Mr. J. B. Carruthers, the government mycologist and assistant director of the Royal Botanic Gardens of Ceylon, to be director of agriculture and government botanist. "The Federated Malay States have an area of more than 25,000 square miles, and the agricultural potentialities are very promising. Large areas are being planted with rubber plants, and sugar and cocoanuts are extensively cultivated. There are two botanic gardens and a rubber experiment station in the Malay States, and all three are, we understand, to be administered by the new department."

The American Association of Farmers' Institute Workers held its ninth annual meeting in the Agricultural Building on the World's Fair Grounds, St. Louis, October 18-20. About 100 members, representing 30 states and provinces in the United States and Canada, were present, and the meeting was considered one of the most successful and helpful ever held. President J. C. Hardy, of Mississippi, was élected president of the association, and G. C. Creelman, of Guelph, Canada, was elected secretary. It was decided to hold the meeting next year at Baton Rouge, La.

It is announced in *Nature* that Dr. Robert Koch has retired from the post of director of the Institute for Infectious Diseases, at Berlin, owing to the increasing demands which other bacteriological work make upon his time and energies. Prof. Koch will proceed to German East Africa in order to continue those studies of tropical and other diseases which he had not completed during his recent visit to Rhodesia. In particular he will continue to investigate the part played by ticks in conveying the infection of various cattle diseases.

Thomas J. Dwyer died at his home in Cornwall, N. Y., October 3, from the effects of a strain which resulted in aneurism of the right artery. He was 49 years old. He was the author of a book entitled Guide to Hardy Fruits and Ornamentals, published in 1903, of which the second edition has already been printed.

O

EXPERIMENT STATION RECORD.

Vol. XVI. December, 1904. No. 4.

The relation of the experiment station to the department of instruction and to various forms of extension work in agriculture proved a very live topic of discussion at the recent annual convention of the Association of American Agricultural Colleges and Experiment Stations, at Des Moines. The matter came up on several occasions in the general sessions of the convention, and the question "How much teaching, if any, is it desirable that a station worker should do?" was a special theme for conference before the section on experiment station work. The general tenor of this discussion and the attitude in which it was approached were most gratifying, and evidenced a clearer appreciation of the important field and the higher purpose of the experiment station.

A great deal has been said of the advantage to the station man of being connected with the teaching force of the college, of coming in contact with students, and of so presenting his work that it will be within their grasp. It has been urged as an inspiration to the investigator, and a safeguard against straying too far from the practical in the ultimate aim of his work. The practice of requiring station men to serve in this dual capacity has been very general ever since the stations were established, and at present about fifty-four per cent of the station workers do more or less teaching. The amount varies greatly, a few giving only a limited number of lectures on advanced subjects, while others carry an entire department of instruction, either alone or with the aid of young assistants. "The tendency seems to be toward an increase in the number of station men who are also doing teaching work," and apparently also toward a greater rather than a less amount of teaching on the average. This is due, in part at least, to the recent growth of agricultural education and the differentiation of agricultural instruction, which have made the demand for additional instructors more pressing.

While it was quite generally conceded by the speakers at this conference that a "certain amount" of teaching might be advantageous to station workers, there was equal unanimity that an uncertain or indefinite

amount is not advantageous, but is often prohibitory of any work which can be regarded as investigation. The kind of teaching required is also an important consideration. The distinction was emphatically made between teaching elementary branches, or the fundamentals, and advanced work. The teaching done at the agricultural colleges in this country is of necessity very largely the teaching of fundamentals, and this was held to be a disadvantage rather than an advantage to the investigator. One director of long experience declared the claim that the teaching of fundamentals and the drilling of classes for fifty per cent of his time is an advantage to the investigator to be "nothing but a pleasant fallacy."

Ten to twenty lectures a year by the heads of departments was mentioned by several speakers as a fair amount which might be conceded to be an advantage to the worker, as a means of gathering himself together and clarifying his views; and others mentioned a course of advanced instruction occupying six hours a week and so arranged as to leave three days a week entirely free from teaching. All agreed that any considerable amount of teaching, even of advanced grade, was disadvantageous to the station worker, as it distracted his thoughts from his investigation and consumed or broke up his time.

Few men have the faculty which enables them to pass readily from their teaching work to their investigation, or to utilize to advantage for that purpose fragments of time represented by a few hours scattered through the day. There is great loss of energy and of efficiency under such conditions, and the spare time is likely to be largely frittered away. The situation might often be relieved by greater consideration for the station men in arranging the schedule of instruction. The time of a half-station man may be so completely broken up by two or three periods of class-room work a day that only work of the simplest kind, requiring the minimum of attention, is possible. Some institutions arrange to have the teaching of such men come during a certain part of the day, or on alternate days, or during half the year, so as to leave more time free from interruption. If a part of the year can be left free from college duties, one serious objection to the dual service is met.

Again, the uncertainty of the amount of college work liable to be required of him introduces an element of doubt which often discourages the station worker from planning any investigation requiring his continued attention. Many exigencies arise in college work, such as an extra large class, the demand for a course not usually given, pressure of short courses, absence of the regular college instructor, and the like, in which case the station man is pressed into extra service; and these contingencies often tend to make the station man feel that his time is not his own until the college term has closed.

A number of stations where the division of time has heretofore been satisfactory, owing to the limited demand for agricultural instruction, are now becoming embarrassed by the increased call for their services in that line. These stations frankly admit that unless additional funds can be secured to provide adequately for the teaching work they can not hope to maintain the high position in agricultural research which they have occupied. This is one of the dangers of the increased interest in agricultural education and the differentiation of agricultural courses. The number of students increases and courses are multiplied, without increased appropriations or any material aid to the teaching force, and the erstwhile investigator finds himself doing full teaching work, with lectures to be revised and adapted, examination papers, practicums, faculty duties, and students coming to him for advice and assistance.

Every station director of experience will admit that the undivided time of one man is far more effective and valuable to the station than half the time of two men with college duties. As one speaker put it, "In this matter two and two do not always make four. I am sure that two half men are not anywhere equal to one whole man, and to go still further, I do not think that four quarter men are worth anything" (in investigation). This strikes the keynote of a popular delusion.

The effect of the dual position on the character of station work and the development of agricultural investigation is an important point to be considered in this connection. There is a vast difference in the quality of station work, growing out of the men themselves, and the conditions under which they are working. Many men have been placed upon the station staff as a matter of expediency or custom who are not suited to the work and who regard it as an added burden. Because a man is a good teacher it does not follow that he will make a resourceful and energetic experimenter. Much of the work done at the stations is not investigation or research in the proper sense of the word. It is merely the testing of this or that crop, this or that method of culture or fertilizer, a comparison of rotations or of feeding rations, or a demonstration of some fact which has been worked out elsewhere. The nature of the case prevents it being more than this.

If we look the ground over we shall find as a very general rule that our best investigation has been done by those workers who have had least teaching to do, and, conversely, that the stations whose workers have had practically to carry their respective departments in the college—and there have been many such—have added comparatively little to the sum of agricultural knowledge. There are few exceptions to this rule, and the converse condition is so common as to be much in evidence and to keep down the average grade of experiment station work in this country.

In an address delivered at one of the congresses at St. Louis this fall Dr. David Starr Jordan quoted one of his correspondents as criticising the work in agricultural science in this country, where it is more largely endowed than in any other country, on the ground that there was too much striving for practical applications, and not enough time given for the fundamental research on which these applications must rest. "The proportion of applied science in agriculture is too great in this country. While we do not need fewer workers in applied agricultural science, we do need more workers who would devote themselves to fundamental research."

This is a fair statement of a condition, with no attempt to assign a cause. One of the fundamental causes is undoubtedly the conditions referred to above. Many a station worker is compelled by the character of his college duties to become little more than a consulting expert in his line, confining himself to the answering of correspondence and conducting a few trials or experiments, and is obliged to forego undertaking anything in the nature of an investigation. There can be no gainsaying the fact that this dual service has done much to retard the development of agricultural investigation and to discourage the efforts of investigators of much promise.

The ultimate result is the only criterion by which the advantage or disadvantage of such a practice can properly be judged. We have had practically fifteen years of experience with it, under a great variety of conditions, and it is certainly a poor theory that will not justify itself in that time. Any division of a station man's time is unwise, even though his salary may seem to be justified on the theoretical number of hours he is expected to teach, when it defeats the real purpose had in view in adding this man to the station staff and robs him of the opportunity to do work of a high order.

More men are needed for real investigation, and it is only reasonable to expect that conditions will be so shaped that we may make progress in that direction. The kind of men needed for investigators was defined by one speaker as "a man saturated with the things he is doing, and who shall not be turned aside and wearied by having to drill a class or do anything else but hunt his subject and the truth." Another speaker believed that teaching and investigating "call for a different attitude of mind and the use of a different set of faculties, to a certain extent, and that except in the case of unusually gifted men the same men are not likely to have both sides equally developed. An investigator should have his mind focused on his work more or less all the time," whereas the teacher's thought will be largely pedagogical.

Considered in the light of the extensive experience which has been had, the most that can be said for the dual arrangement, where any

considerable amount of teaching is involved, is that it is solely a matter of expediency. Dividing the salary enables both the college and the station to carry a larger number of men on its agricultural staff, to differentiate its work more, and make a show of carrying a larger number of departments; but from the standpoint of real investigation the advantage of this increased number of half or quarter men in the station is decidedly problematical. The efficiency of a station is not measured by the fractions of men it has on its staff, and it must be said that some of the stations with the longest corps of workers on their roster have contributed least to the real advancement of agricultural science and practice.

Every station man should, if practicable, do some teaching or farmers' institute work, as a means of keeping his mind directed toward the practical bearing of his investigations, and of enabling him to present them to students or farmers in an intelligible manner. But the amount should not be large or so arranged as to scatter his efforts. It should be of advanced character, and if so will naturally relate to the experimental work in hand and the results accomplished by the investigator himself and others in his particular department, together with their practical significance. Then it will not distract his mind from his work and will usually be helpful. But it must be admitted that the requirement of a large amount of elementary teaching is one of the weaknesses of our American station system, attributable to the lack of adequate funds to properly meet the rapid increase in demand for agricultural education, which has been greatly stimulated by the work of the experiment stations.

Considering the splendid work of the stations as a whole, and the potent and far-reaching influence they have exerted, not only in improving agricultural methods but in bringing about a better attitude of mind, any criticism of the returns they have rendered for the funds which have been at their disposal would be most unjust. The condition is to be taken rather as an indication of the pressing need of larger funds by both the agricultural college and the experiment station, to properly man the teaching force and to develop the department of agricultural investigation.

The former views regarding the needs of the experiment station have been modified in several important respects in recent years. The conference at Des Moines brought out the fact that a modification of the views regarding the dual function of the station worker is now clearly indicated, and that a considerable number of stations are moving as rapidly as opportunities permit in the direction of a station staff whose members shall be primarily station men. The well-nigh unanimity of opinion among station directors and workers, especially among those who are carrying on real investigation, should outweigh the theoretical claims which these fifteen years of experience

have failed to realize upon. They should lead college presidents and boards of control to deal with this question as one of the most vital at present affecting experiment station work; and it is especially desirable that it be looked squarely in the face and considered impartially at this time, when plans are being made for the use of larger funds to strengthen and develop the station work.

Another line of discussion touching the experiment stations was the provision for extension work as a branch of the agricultural college. There was a more general recognition of the fact that the agricultural college logically embraces three distinct branches or departments of work, viz, the experiment station or research department, the department of instruction, and the department for extension work. President Butterfield declared that "to carry out the function of the agricultural college we need a vast enlargement of extension work among farmers," which should be dignified by a standing in the college coordinate with research and the teaching of students. It should rank as a distinct department "with a faculty of men whose chief business is to teach the people who can not come to the college."

Among the lines of work assigned to this extension department were included the farmers' institutes, reading courses, extension lectures, the carrying on of cooperative and demonstration experiments, the editing and distributing of such compilations of practical information as now appear under the guise of experiment station bulletins, and eventually relieving the station of the bulk of its correspondence.

It was frankly admitted that the compiled popular publications which the stations have been practically forced into issuing as a matter of protection of their time are not properly station bulletins, and create a wrong idea as to the character of work which the stations are putting out. Like much of the station correspondence, it was held to belong in the extension department. The demand for the information and the personal inquiries have grown up with and out of the experiment stations, which have created a thirst among farmers for more up-to-date knowledge and for advice, which they turn to the station men to supply.

There was a strong sentiment voiced by a number of speakers that if the experiment stations are to fulfill in the highest degree the expectations which have been placed in them as agencies for research in agriculture—for adding to our fund of scientific knowledge and applying it to the practical problems in agriculture—they must cease to be all things to all men, they must be relieved of this great drain upon them, and allowed to devote themselves to their special field.

To meet this demand a special agency is needed for disseminating and demonstrating new discoveries and new methods; and the extension department, which is already organized and in operation at Cor-

nell University, and which exists in embryo at a number of other places, was confidently pointed to as one of the departments of the agricultural college of the future.

The interest in this movement was voiced by a resolution to secure if possible the granting of the franking privilege to the publications of the extension department, and thus allow them to stand for what they are, instead of distributing them under the cloak of bulletins of the experiment station. The expense of sending them out otherwise is now the only reason assigned for issuing them in the station series, and it was argued that the extension of the franking privilege to bulletins of this department of work would allow a clear and distinct differentiation of the legitimate work of the experiment station, and thereby complete the organization.

The resolution was ultimately withdrawn, but the interest with which it was discussed indicated how widespread is the feeling that the stations and their publications are being burdened with a class of material which is not strictly in their domain, and which a more complete organization of the college of agriculture should provide for in another way. It represented a very notable advance in opinion, and is a most encouraging sign of a broader and clearer conception of the respective functions and needs of agricultural instruction, agricultural experimentation, and agricultural extension, which combined go to make up the agricultural college of the future.

It was recognized that in the case of many institutions the programme is to some extent more ideal than practicable under present conditions. The change can not come all at once, but it will be something to work toward now that the need is more evident; and with the possibility of securing increased funds for agricultural work, which in many of the States is now exceptionally good, the realization of some of these ideals seems nearer at hand.

CONVENTION OF ASSOCIATION OF OFFICIAL AGRICULTURAL CHEMISTS, 1904.

The twenty-first annual convention of this association was held at St. Louis, September 26–28, 1904. The meetings were held in room 1 of the Hall of Congresses at the Louisiana Purchase Exposition. Eighty-eight members and visitors were in attendance. In the absence of the president, M. E. Jaffa, and the vice-president, C. L. Penny, W. A. Withers presided on request of the association.

The regular business of the convention was completed during the first two days, but on the morning of the third day a joint session was held with the Association of American Fertilizer Manufacturers, in the Agricultural Building.

The following officers were elected for the coming year: *President*, C. L. Penny, Newark, Del.; *Vice-president*, C. G. Hopkins, Urbana, Ill.; *Secretary*, H. W. Wiley, Washington, D. C.; *Additional members of executive committee*, C. A. Browne, jr., New Orleans, La., and R. W. Thatcher, Pullman, Wash. The list of referees and associates has not been completed, but will be announced in a later issue. Washington was decided upon as the place of the next meeting.

The reports and papers presented at the convention, and the more important action of the association, are briefly summarized below under appropriate headings. A somewhat fuller statement of the recommendations acted upon at this convention has been issued as Circular No. 20 of the Bureau of Chemistry.

POTASH.

The report on this subject, presented by F. B. Carpenter, referee, detailed the results of a study of the sodium-hydrate method proposed last year, and a continuation of the study of methods for the determination of moisture in potash salts. All of the results by the official Lindo-Gladding method were considerably under the theoretical, while those by the modified method, using sodium hydrate instead of ammonium hydrate for neutralizing, with a few exceptions came much nearer to the calculated percentages. It was thought that some of the variations observed in the use of the modified method were due to the presence of potash in the sodium hydrate. The results on the

determination of moisture in kainit "simply confirm our previous experience and show how unsatisfactory our present official method is." The referee suggested that an arbitrary method of procedure be adopted for this determination, and proposed the heating of 2 gm. of substance at 130° C. in an oil oven for 10 hours, the loss in weight to be considered as moisture. This recommendation was referred to the referee for next year for further study.

A paper by M. G. Douk reported Experiments on the Volumetric Estimation of Potash as Phosphomolybdate. Trials of the Wavelet method (E. S. R., 12, p. 713) gave results which were too low and quite irregular. To avoid the difficulties of this method and to make it more generally applicable, the author worked out a method for titrating the yellow precipitate, which he described in some detail. The results of a few comparative trials with the official method are reported. "The method is exceedingly rapid and easy of execution, necessitating no operation by which loss of potash is liable to occur."

Recommendations.—The recommendation of the referee that the sodium-hydrate method, which has been tried for two years with favorable results, be adopted by the association was followed, but the method can not be made official until the next year's meeting. The method as suggested is as follows: Boil 10 gm. of the sample with 300 cc. of water plus 5 cc. of hydrochloric acid for 30 minutes; add a few drops of phenolphthalein and carefully neutralize with sodium hydrate free from potash, avoiding a large excess; add sufficient powdered ammonium oxalate to precipitate all the lime; cool, dilute to 500 cc., mix and pass through a dry filter, then proceed as in the Lindo-Gladding method.

PHOSPHORIC ACID.

C. B. Williams, referee, in the report on this subject, dealt mainly with the question of the proper basis for valuation of phosphatic fertilizers, particularly slag. The results for total phosphoric acid on 3 samples of slag were quite concordant in the case of the same analyst using the same method of solution, but there was often considerable variation between the results of different analysts, and between the results of the same analysts using different solvents. In the case of available phosphoric acid there was also considerable variation between workers by the same method and on the same sample. The ammonium chlorid citric acid method and the cane sugar citric acid method were the two methods which acted most energetically upon the slag, but as no data were obtained from either field or pot tests, it was impossible to say which of the solvents came nearest to representing what different plants would be able to take up from the soil in an average season.

Duplicate results secured in the determination of available lime by the 10 per cent ammonium chlorid method were tolerably concordant for each worker, but there were wide differences between analysts.

A paper by B. L. Hartwell and J. W. Kellogg, presented by H. J. Wheeler, discussed The Effect upon the Residue after Extracting the Soluble Phosphoric Acid of Postponing the Treatment with Ammonium Citrate. The differences between the amount of reverted phosphoric acid as determined at once and after standing 15 weeks were in nearly all cases within the limit of error liable to occur under the conditions of the work. The results indicated that "no large error will arise if, for the sake of greater convenience, the dried residues from the extraction with water are kept a number of weeks before the reverted phosphoric acid is removed by the ammonium citrate." The relative value of open-hearth and ordinary basic slag, and of raw and roasted redondite, was briefly discussed by several members.

A paper on the Estimation of Small Quantities of Phosphoric Acid by the Volumetric Method was read by F. P. Veitch. The deduction from the results presented was that "accurate results can be obtained on such small quantities of phosphoric acid as exist in drainage waters and water extracts of soils, neither evaporation nor filtration appearing to affect the results seriously."

Recommendations.—The referee for the coming year was instructed to continue the study of methods of determining total and available phosphoric acid in slag, and also to study the solubility of phosphoric acid in the same samples of slag reduced to different degrees of fineness. It was also recommended that the referee plan field and pot experiments with cultivated plants, looking toward the determination of the relative value of the total phosphoric acid of slag, Redonda, and precipitated phosphates of different degrees of fineness, in comparison with that of the phosphoric acid in acid phosphate and other common phosphatic materials, and invite cooperation in this undertaking on as many soil types and by as many workers as possible.

NITROGEN.

The report of the referee, C. H. Jones, read by F. C. Weber, was devoted mainly to a comparison of the neutral and alkaline permanganate methods for determining the availability of nitrogen in fertilizers. The reports received from 15 chemists were on the whole very satisfactory. The results by the neutral permanganate method agreed closely and indicated that, if directions are followed in the digestion with permanganate solution, uniformity may be obtained among different analysts. The chief trouble found in operating the alkaline method seemed to be from excessive frothing during distillation and an uncertainty as to when to stop. Serious frothing may be avoided, according

to the referee, by increasing the heat gradually after the 30 minutes digestion.

A paper by G. S. Fraps briefly summarized the results of studies on the nitrification test for availability of nitrogenous fertilizers.

A report on the separation of vegetable proteids, by J. S. Chamberlain, associate referee, gave the results of a study of wheat proteids, and referred mainly to the difficulty of securing a clear separation of groups by the use of alcohol and salt solution as solvents. The referee recommended that for the present no attempt be made to separate the proteids of wheat into individuals, but that they be given designations according to their solubility or insolubility in alcohol and dilute salt solution. It was also recommended that the total proteids be calculated from the total nitrogen as determined by the Gunning method, using the factor 5.68.

A report on the separation of meat proteids, by W. D. Bigelow, associate referee, was confined to the separation of the nitrogenous bodies in meat extracts, and was mainly a repetition of the work reported on last year. Zinc sulphate, phosphotungstic acid, and tannin salt were employed as precipitants and tested singly and in combinations. The combination precipitating the greatest amount of nitrogen was phosphotungstic acid followed by the tannin salt reagent. The amount of nitrogen precipitated by phosphotungstic acid was greater in each case than that precipitated by any other single reagent. "From the present results, confirming in the main those reported a year ago, it is believed that the most complete precipitation of all proteid bodies, including albumoses and peptones, may be obtained by means of phosphotungstic acid, followed by tannin salt reagent in the filtrate from the phosphotungstic acid precipitate." Results with zinc sulphate "do not have the conformity that is desired." In his recommendations the associate referee outlined methods for ammonia, acidity, phosphorus, chlorin, and xanthin bases (Schittenhelm's method) for adoption by the association.

Recommendations.—On recommendation of the referee (C. H. Jones), a modified form of the alkaline permanganate method was made provisional, and the referee was instructed to further compare the alkaline and neutral permanganate methods, with a view to determining the amount of material to be used in each test. The modified alkaline permanganate method is as follows: Using an amount of sample containing 0.045 gm. of organic nitrogen, digest for 30 minutes below the boiling point in a 600 cc. distilling flask connected with condenser to which the receiver containing standard acid has been attached, with 100 cc. of alkaline permanganate solution (16 gm. $KMnO_4$ and 150 gm. of NaOH dissolved in water and made to 1 liter). Then boil until 85 cc. of distillate is obtained. If the material shows a tendency to adhere

to the sides of the flask an occasional gentle rotation is necessary during distillation. The recommendations of Mr. Chamberlain and Dr. Bigelow relative to the separation of vegetable proteids and meat proteids, respectively, were adopted by the association and directed to be printed as outlined by the referees.

ASH.

The report on ash, submitted by the referee, R. W. Thatcher, gave special attention to methods of determining sulphur in plant tissues. The peroxid method was reported to give higher results than the nitric acid method, but in cases where the sulphur content was known neither method gave results approximating the total amount of sulphur.

There was some discussion of the importance of ash analysis and of defining the terms "ash" and "plant food." On motion of H. J. Wheeler a committee of five was appointed to confer with a similar committee of the botanical section of the American Association for the Advancement of Science with reference to the definition of the term "plant food." This committee consists of H. W. Wiley, H. J. Wheeler, L. L. Van Slyke, E. W. Magruder, and B. W. Kilgore.

Recommendations.—The referee was instructed to continue the study of the peroxid and nitric acid methods, and to make determinations of the total sulphur in samples used for cooperative work by the Barlow-Tollens method of combustion in a closed tube.

SOILS.

C. G. Hopkins, referee, presented the report on this subject, which dealt largely with a comparison of the results obtained by the official methods and those of the Bureau of Soils, as given in Bulletin 22 of that Bureau, especially the colorimetric methods. The results by the two methods showed considerable discrepancies, and the discussion led to the presentation of the following resolution by L. L. Van Slyke:

Whereas the methods employed by the Association of Official Agricultural Chemists for the analysis of soils and those employed by the Bureau of Soils of the U. S. Department of Agriculture yield such entirely different results where they should be identical,

Resolved, That a committee be appointed to consider the matter and to consult with the Secretary of Agriculture with a view to bringing about greater harmony in respect to methods employed in soil analysis in the United States and the conclusions based upon such analyses.

The committee appointed consists of L. L. Van Slyke, H. J. Wheeler, and F. K. Cameron.

In the course of his report as referee Dr. Hopkins referred to the use of different terms in stating the results of analysis, some chemists, for example, using "ammonia" instead of "nitrogen," and some

"potash," while others use "potassium," etc. As a result of discussion upon this point, the following committee on the unification of terms for reporting analytical results was appointed: R. J. Davidson, chairman, C. G. Hopkins, W. D. Bigelow, G. S. Fraps, and C. A. Browne, jr.

G. S. Fraps read a paper on Nitrification and Soil Deficiencies, in which he referred to nitrification as a means of determining these deficiencies, pointing out the relation of moisture, basicity, phosphoric acid, potash, etc., to nitrification. He showed that the varying power of soils to transform organic matter into nitrates under comparable physical conditions was due in part to deficiency in available calcium carbonate, potash, or phosphoric acid. Furthermore, "a deficiency in phosphoric acid for nitrification is as a rule accompanied, in the cases under observation, by a deficiency in phosphoric acid for corn and cotton." He held that investigations into the causes of the variation in nitrifying power of soils and the relation between soil deficiencies as shown by nitrification and pot experiments have an important bearing upon problems of soil chemistry and the maintenance of soil fertility.

F. P. Veitch presented a Summary of Experiments on the Relation of Soil Acidity to Fertility. The paper was based largely upon the results of pot experiments made by the Bureau of Chemistry on soils from different parts of the United States, and showed in general that all of the principal factors of soil fertility are more active in alkaline than in acid soils. The physical condition is better, there is less disease, and plants make better use of all the elements of plant food, except phosphoric acid, in alkaline soils. There was considerable discussion of the rate of liming, the depth to which applications of lime penetrate into the soil, the form of lime to be used, etc. Mr. Veitch's paper stated that "in applying lime the soil should finally be made alkaline to the full plowed depth," and that "in ordinary farm practice the acids of the subsoil are not neutralized by the applied lime."

Recommendations.—It was recommended that the investigation of methods for the determination of water-soluble plant food in soils be continued; and that the methods for determining the easily soluble plant food also be further investigated, using acid solutions of greater strength than two-hundredth-normal, as previously recommended.

DAIRY PRODUCTS.

The report on this subject, by G. E. Patrick, referee, was read by the secretary. It dealt mainly with the effect of preservative materials on the albumin of milk, and the determination of sugar in condensed milk.

Recommendations.—The study of the effect of preservatives on the albumin of milk and methods of detecting renovated butters is to be continued, and the referee was requested to study also methods for determining sugars in condensed milk and milk powders.

SUGAR.

The report of the referee, L. S. Munson, detailed the efforts to secure the cooperation of the association with the committee of the International Commission for Unifying Methods of Sugar Analysis, having under consideration the revision of methods for reducing sugars. The International Commission meets in Rome in 1906, at which time the question will be taken up; and the referee expressed his opinion that the efforts of the association in this line of work during the next coming years might well be directed to this problem.

A report on Special Analytical Methods of Sugar Analysis, by C. A. Browne, jr., associate referee, dealt with (1) the determination of levulose in the presence of dextrose and sucrose, and (2) the nature of various gums found in sugar-cane products. The work reported under the first part led to the conclusion that neither the optical nor the combination method for the determination of levulose, as they stand at present, is as exact as the polariscopic determination of sucrose, although both methods give a fairly close approximation. It was recommended that succeeding referees undertake the perfection of a method for the determination of levulose and dextrose in the presence of sucrose.

A study of the various gums occurring in sugar-cane products, carried out by Dr. Browne at the Louisiana Sugar Station, has led to the finding of a series of gums which may be divided into two classes. The first class contains gum products derived naturally from the hemicelluloses of the cane fiber, and includes xylan, araban, and traces of galactan. The amount of these gums which passes into the juice, sirup, and molasses varies according to the pressure of the rollers, the degree of maceration which the cane receives during milling, and the variety of the cane. The second class of gums do not occur naturally in the cane, but are the result of fermentation processes which set in either before or after the expression of the juice. Dextran, cellulan, mannan, levulan, and levan are examples of such fermentation gums. The properties of the gums of the two classes enumerated above were described, and it was noted that other gums of an unknown character which have been separated from cane molasses are undergoing identification.

A report on methods for the analysis of molasses, by H. E. Sawyer, associate referee, described briefly the work done, which is to be published later; and J. E. Halligan presented a paper on Analyses of

Molasses Produced by Different Methods of Manufacture, and Comparison of Methods for Determining Total Solids.

Recommendations.—The referee and his associate on mechanical methods for sugar analysis were directed to devote as much time as seemed desirable during the coming year to cooperation with the committee of the International Commission for Unifying Methods of Sugar Analysis; to continue testing the methods for the determination of levulose and dextrose in the presence of sucrose; to continue the study of methods for the identification and analysis of vegetable gums; and to take steps toward perfecting methods for the determination of caramel and other organic solids which accompany sugar in cane and beet products. It was suggested that the referee test the use of neutral oxalate of potash in place of sodium carbonate as a precipitant for lead in clarified sugar solutions, and he was requested to submit to collaborative test next year the method of molasses analysis outlined at the meeting in 1903 (E. S. R., 15, p. 440), which is soon to be published in detail.

FOOD ADULTERATION.

Reports were read on colors, by Milton G. Berry; distilled liquors, by C. A. Crampton; baking powder and baking powder chemicals, by R. O. Brooks; tea and coffee, by Hermann C. Lythgoe; beer, by H. E. Barnard; fats and oils, by L. M. Tolman; and dairy products, by A. E. Leach. W. Frear and R. O. Brooks called attention, in a short note, to a Limitation of the Arata and the Sostegni and Carpentieri Tests. The report on colors is a compilation and was submitted only in outline. It is to be published in full in circular form. The report on distilled liquors gave the results on three samples of liquors by a number of collaborators, which were quite satisfactory, indicating the present methods of the association to be efficient. The other reports detailed rather briefly the work done on special methods, and were largely reports of progress.

Recommendations.—Practically no changes of importance were made in the official methods relating to food adulteration, and the recommendations related to the further testing of methods which have been suggested for various products and the consideration by the referee for next year of various suggestions made in the reports of the associate referees at this meeting. Provisional methods were adopted for tea and coffee, which are too lengthy for publication here.

TANNIN.

The referee for this subject, G. A. Kerr, presented a report on analyses of wood extracts, fresh and leached bark, and fresh chestnut wood by the official method; studies on the cause of variation in soluble and insoluble matter found in extracts; and a further investigation of

the provisional methods for determination of acids in yard liquors. A provisional method for the analysis of barks, woods, leaves, etc., was given in detail. The referee suggested that further research be made to determine the limit of temperature at which the determination of soluble and insoluble matter should be carried out.

. Two papers were presented by F. P. Veitch, one on the Extraction of Tannin Materials with Different Extractors, and the other A Discussion of Methods for the Estimation of Tannin.

Recommendations.—The recommendation of the referee that further study be made to determine the limit of temperature at which soluble and insoluble matter should be determined was adopted, and the method described by him in his report for the analysis of barks, woods, etc., was ordered printed as a provisional method, work upon it to be continued until it has been further perfected. The method for the determination of acid in tannin solutions, with the alternative of using the coal-charcoal method, was continued as a provisional method, to be given further study; and the referee for 1905 was instructed to make a study of present methods of analysis of tannery yard liquors, especially spent or sap liquors. The recommendations submitted in the report for 1903 (Bureau of Chemistry Bulletin No. 73) were adopted and ordered to be embodied in the official methods. These changes relate to weighing in a weighing bottle fitted with a glass stopper, and covering the funnel with a plate during filtration to guard against evaporation.

INSECTICIDES, FUNGICIDES, AND DISINFECTANTS.

The report on this subject, by Bernard H. Smith, referee, was read by the secretary. In general the work followed closely the lines of previous years, the principal new feature being a study of disinfectants. Results of cooperative studies were given for Paris green, London purple, copper carbonate, soda lye, formaldehyde and nicotin, together with the comments of the analysts. A paper on The Determination of Lime and Sulphur in Solutions of Sulphids or Polysulphids used as Insecticides, by S. Avery, associate referee, was read by title.

There was considerable discussion of the subject of insecticides and disinfectants, attention being called especially to the poor quality of commercial formalin and copper sulphate, and to the use of sulphurous acid for bleaching dried fruits and grain (oats). The adoption of standards for these materials was advocated by several speakers.

Recommendations.—The modifications of the Avery-Beans method for determining total arsenious acid in Paris green, noted under *b*, p. 197, and *c*, p. 198, in the proceedings of the last convention,[a] were made optional methods. For the titration of arsenic twentieth-normal instead of deci-normal iodin was adopted. The electrolytic method for determining copper in Paris green and copper carbonate was made

[a] U. S. Dept. Agr., Bureau of Chemistry Bul. 81.

official, and the thiosulphate method, using twentieth-normal instead of deci-normal thiosulphate, was made optional. The volumetric silver-nitrate method, for determining cyanogen in potassium cyanid, was adopted as official, using twentieth-normal instead of deci-normal solution of silver nitrate, and the Kissling method for nicotin was also made official. The Blank and Finkenbiener peroxid method was adopted as official for formaldehyde in strong solutions and the Romjyn potassium-cyanid method for analyzing dilute solutions. The hydrogen-peroxid method, suggested by Avery, for determining sulphur in sulphur dips and similar compounds was made a provisional method, to be further tested by the association.

MISCELLANEOUS REPORTS.

Foods and feeding stuffs.—The referee on this subject stated that no cooperative work had been done and that there was no report to be made.

Food standards.—The committee on food standards presented a report prepared by the chairman, W. Frear, which was read by the secretary. It gave a brief account of a conference with representatives of manufacturers and others with respect to standards for articles not included in the schedules proclaimed November 20, 1903. No results of this meeting were given. The committee has prepared for publication at an early date tentative standards for articles belonging to the schedules of cereals and their milling products, fruits, honey, salad oils, vinegar, and fruit juices.

Medicinal plants and drugs.—L. F. Kebler, referee, submitted the report on this subject, emphasizing the need of standards and of more careful tests of these materials.

Testing of chemicals and apparatus.—The report of the committee on this subject, appointed to cooperate with a similar committee of the American Chemical Society, emphasized the need of more careful calibration of apparatus and tests of the chemicals used.

Fertilizer legislation.—H. W. Wiley, as chairman of the committee on fertilizer legislation, submitted a brief report. It was suggested that standards of purity for fertilizers and fertilizing materials might be adopted as has been done in the case of foods, and as a tentative step in this direction definitions of the terms "fertilizer" and "fertilizer ingredient" and of what constitutes adulteration were submitted. There was considerable discussion of the desirability of drafting a national law controlling interstate commerce in fertilizers, which would include definitions along the line of those enumerated, but no definite action was taken. A communication was read from E. W. Hilgard regarding the subject of uniform fertilizer legislation and the enactment of a Federal law (the latter not being regarded with favor), and referring specifically to the California fertilizer law.

RECENT WORK IN AGRICULTURAL SCIENCE.

CHEMISTRY.

On Ritthausen's classification of the plant proteids, D. Prianishnikov (*Landw. Vers. Stat., 60 (1904), No. 1–2, pp. 15–27*).—A consideration of available experimental data led to the conclusion that Ritthausen's classification of proteids needs some modification.

The author divides the proteid group into water-soluble proteids (plant albumen), proteids insoluble in water but soluble in hydrochloric acid (plant globulin), proteids soluble in 70 to 80 per cent alcohol and precipitated with a small quantity of sodium chlorid, for instance, gliadin, and proteids (rich in P_2O_5) insoluble in the above-named reagents, but capable of being extracted with alkalis and precipitated with acids, for instance, gluten casein. In addition the plants contain proteids of smaller molecular weight (peptones and albumoses), which may be regarded as intermediary products of hydrolysis, and also bodies (for instance, nucleins) with molecular weight higher than proteids.

The author believes that legumin and conglutin should not be regarded as plant caseins, but as belonging to a special group of plant globulins.

On the action of 4 per cent sulphuric acid on legumin, D. Prianishnikov (*Landw. Vers. Stat., 60 (1904), No. 1–2, pp. 27–40, fig. 1*).—According to the author's experiments 4 per cent sulphuric acid when warmed with legumin causes a marked reaction. It quickly acts upon the legumin and changes it into compounds which are not precipitated with copper oxid. The author considers it probable that dilute acid causes a cleavage of the proteid molecule with the formation of amido acids. The other cleavage products are spoken of.

The occurrence of hexone bases in the tubers of potatoes (Solanum tuberosum) and the dahlia (Dahlia variabilis), E. Schulze (*Landw. Vers. Stat., 59 (1904), No. 5–6, pp. 331–343*).—The investigations reported led to the conclusion that histidin and lysin are contained in the juice of potato tubers, and that arginin was present in these tubers and also in dahlias. According to the author, these facts furnish additional reasons for believing that the juice of roots and tubers contains a mixture of crystallizable nitrogenous compounds, which in composition closely resemble that present in etiolated germinating plants.

The molecular weight of glycogen, Mme. Z. Gatin-Gružewska (*Arch. Physiol. [Pflüger], 103 (1904), No. 5–6, pp. 282–286*).—The results of cryoscopic investigations, in the author's opinion, showed that the ordinarily accepted data for the molecular weight of glycogen are not trustworthy. The subject is discussed from the standpoint of physical chemistry.

Determination of phosphoric acid by the weight of the molybdic precipitate, S. Brushlinski (*Zhur. Opuitn. Agron. [Jour. Expt. Landw.], 4 (1903), No. 5, pp. 525–527*).—The author made 10 determinations of phosphoric acid by the Lorenz method of direct weighing of the molybdic precipitate obtained by means of a molybdic solution containing sulphuric acid and nitric acid, modifying the method by using the ordinary nitric-acid solution. Very accurate results on solutions of known composition were obtained.—P. FIREMAN.

Determination of potash, N. TARUGI (*Gaz. Chim. Ital., 34 (1904), I, pp. 324–341; abs. in Chem. Centbl., 1904, II, No. 4, p. 366*).—Organic matter in about 1 gm. of substance is destroyed by treatment with concentrated sulphuric acid, and hydrochloric acid, sulphuric acid, and ammonium salts are removed by ignition. The residue is dissolved in 10 cc. of water and the solution is mixed with 10 cc. of a 15 per cent solution of sodium persulphate ($Na_2S_2O_8$) and placed in a thermostat until its temperature becomes constant.

The mixture is allowed to stand 3 hours at 0° C. for dilute solutions, at room temperature for concentrated solutions, when by adding a small crystal of potassium persulphate the potassium persulphate in the solution crystallizes out. The persulphate content of 10 cc. of the clear supernatant solution is then determined by means of tenth-normal sodium hydroxid and compared with that of the original sodium persulphate solution used. The difference between the two, allowing for dilution, multiplied by 0.0047 and corrected for potassium persulphate dissolved (factors for which are given) represents potash present. Fairly satisfactory results were obtained with the method.

Different methods of mechanical analysis of soils and the method of double sedimentation with a small sample, SABANIN (*Pochvovyedenie* [*Pédologie*], *5 (1903), Nos. 1, 2; abs. in Zhur. Opuitn. Agron.* [*Jour. Expt. Landw.*], *5 (1904), No. 1, pp. 121–123*).—The author critically reviews various methods which have been proposed and describes the following modification of the Fadyeyev-Williams method: Four grams of soil passing through a sieve with 1 mm. holes is made to the consistency of a thin gruel, triturated with the finger 2 to 5 minutes, and transferred to a flask of 125 cc. capacity, in which it is boiled for 1 hour. For the separation of the particles 0.25 to 1 mm. in size a small sieve placed in a porcelain dish of 1½ liters capacity is used.

For the separation of the particles less than 0.01 mm. the turbid liquid is transferred by means of a siphon to a small porcelain dish, from the latter after 100 seconds into a graduated beaker (100 cc. capacity, 8 cm. high), and thence into large (1½ to 2 liters) beakers—process of double sedimentation. Toward the end the soil is triturated with the finger in both dishes in order to bring about complete separation. The separation of the particles 0.01 to 0.05 mm. is effected in a tall cylinder beaker (into which the soil was transferred from the small beaker and the small porcelain dish in order to test the completeness of the last separation) from which the turbid liquid with the suspended particles is transferred every 30 seconds into a large beaker. The same treatment is given to the residue in the large porcelain dish.

The remainder of the soil after this separation represents the particles 0.05 to 0.25 mm. in diameter. In the further division of the 0.01 mm. particles the author, besides the boiling during 24 hours usually practiced in the separation of the 0.001 mm. particles, boils the sediment in a small Erlenmeyer flask and pours the turbid liquid into 3 to 5 small beakers to the height of 4 cm., from which, after 4 hours and 48 minutes, 2 cm. of the liquid is decanted, which hastens the separation. The separation of the particles 0.001 to 0.005 mm. is made in the same kind of beaker.—P. FIREMAN.

Action of hydrochloric acid on the soil under different conditions, S. BRUSHLINSKI (*Zhur. Opuitn. Agron.* [*Jour. Expt. Landw.*], *4 (1903), No. 5, pp. 517–524*).—The author compared the action of hydrochloric acid on soils under varying conditions of time of treatment, concentration of acid, and excess of acid. On the basis of his own experiments and those of other investigators he concludes that the influence of the length of time, within moderate limits, is not marked, that the effect of concentration of the acid is not considerable as long as the variations in this respect are not extreme, and that only the relative quantity of the acid and soil is decisive in respect to the amount of soil going into solution.—P. FIREMAN.

The determination of gliadin in wheat flour by means of the polariscope, H. SNYDER (*Science, n. ser., 19 (1904), No. 481, pp. 442, 443*).—Noted from another publication (E. S. R., 15, p. 849).

Gravimetric estimation of starch of flour, and of commercial starches by the G. Baumert and H. Bode methods, H. WITTE (*Ztschr. Untersuch. Nahr. u. Genussmtl., 7 (1904), No. 2, pp. 65–77*).—A critical study of methods of estimating starch.

Estimation of fat in cheese and foodstuffs, H. L. VISSER (*Chem. Weekbl., 1904, No. 29; abs. in Analyst, 29 (1904), No. 339, pp. 191–194*).—Different methods of estimating the fat in cheese and feeding stuffs were tested, and a modification of the Bondzynski method is proposed.

In the author's opinion, the latter method can not be used for feeding stuffs containing cellulose, since on boiling in hydrochloric acid these form a thick mass from which the fat can not be extracted by shaking with petroleum ether. He, therefore, used the method proposed by Berntrop for bread. Five to 10 gm. of the substance was gently boiled for half an hour with 100 cc. of 10 per cent hydrochloric acid in a beaker covered with a watch glass. After cooling, distilling with water, and filtering, the residue was washed with water until a neutral reaction was observed. The wash water was removed, the filter placed in a thimble, and dried at 100° C. in a current of gas. The fat was then estimated in the usual way by extraction with ether.

In tests with maize, linseed products, rice meal, meat meal, peanut cake, etc., it was noted that the method outlined always gave the higher results, especially in the case of samples containing gluten. The fat from the meat meal was also found to contain creatin. The fat of the peanut cake consisted almost entirely of free fatty acids. These facts may serve as an explanation of the high results given by the extraction methods. The fat obtained from linseed cake after boiling with hydrochloric acid was shown to be pure from its iodin and saponification values and its refractometer figure. For those molasses foodstuffs which contain linseed-cake meal, the only reliable method, according to the author, is that of Berntrop.

Estimation of fat in cheese, B. SJOLLEMA (*Chem. Weekbl., 1904, No. 29; abs. in Analyst, 29 (1904), No. 339, pp. 190, 191*).—Several methods of estimating the fat in cheese were compared. The author concludes that when cheese is ground with a little alcohol and brought at once into a flask with about 50 cc. of ether, allowed to stand some hours with repeated shaking, the ether filtered through a very close filter, and the fat determined, very reliable results are obtained.

The examination and valuation of culinary fats, A. JUCKENACK and R. PASTERNACK (*Ztschr. Untersuch. Nahr. u. Genussmtl., 7 (1904), No. 4, pp. 193–214*).—The investigations reported have to do especially with the analysis of butter and other fats, pure and adulterated.

The natural occurrence and synthetic preparation of mixed fatty acid glycerids, H. KREIS and A. HAFNER (*Ztschr. Untersuch. Nahr. u. Genussmtl., 7 (1904), No. 11, pp. 641–669, pl. 1*).—In the authors' opinion, the investigations reported give the first satisfactory proof of the occurrence of mixed glycerids of fatty acids in animal fats.

The identification of spoiled fat in food products, F. WIEDMANN (*Ztschr. Untersuch. Nahr. u. Genussmtl., 8 (1904), No. 2, pp. 136–139*).—A note on the detection of spoiled fat.

The lithium method of separating saturated fatty acids, K. FARNSTEINER (*Ztschr. Untersuch. Nahr. u. Genussmtl., 8 (1904), No. 2, pp. 129–136*).—A critical study led the author to conclude that the lithium method of separating saturated fatty acids was not reliable. (See E. S. R., 15, p. 748.)

The color reactions of fat oils, H. KREIS (*Verhandl. Naturf. Gesell. Basel, 15 (1904), No. 2, pp. 225–251*).—The only difference which the author could find in 2 sorts of sesame oil was that the sort which gave an azo-color reaction became green

on the addition of sulphuric acid, while the other sort became orange. Color reaction of oils is discussed at length.

The estimation of soluble carbohydrates in foods, G. BENZ (*Ztschr. Untersuch. Nahr. u. Genussmtl., 7 (1904), No. 2, pp. 89, 90*).—A note on the estimation of soluble carbohydrates.

Concerning the identification of different sorts of cinnamon, J. HANUŠ (*Ztschr. Untersuch. Nahr. u. Genussmtl., 7 (1904), No. 11, pp. 669–672*).—The importance of estimating cinnamic aldehyde is spoken of from a number of standpoints.

Report on general work in the chemical laboratory, C. A. GOESSMANN (*Massachusetts Sta. Rpt. 1903, pp. 98–104*).—A brief statement regarding miscellaneous materials examined during the year, and notes on analyses of soils, ashes, Peruvian guano, sugar-beet refuse, and city garbage products. The sugar-beet refuse obtained in the manufacture of alcohol from beet molasses contained 7.7 per cent of water, 9.72 per cent of potash (8.36 per cent soluble), and 6.39 per cent of nitrogen (3.86 per cent in form of nitrate), but no phosphoric acid. The composition of the garbage tankage and garbage ashes was as follows:

Composition of garbage tankage and ashes.

	Tankage.	Ashes.
	Per cent.	*Per cent.*
Water	7.42	3.01
Potash	None.	5.13
Phosphoric acid	[a] 6.06	8.77
Nitrogen	5.96	None.

[a] Available 4.40 per cent.

The tankage "was obtained by heating the selected garbage in vats under pressure By this method the fats are recovered, and the organic nitrogenous matter is preserved for use as a nitrogen source in fertilizers. In this process, however, the greater part of the potash and other salines are leached out. [The ashes] represent the product obtained by the cremation of city garbage. In this material the nitrogen has been sacrificed, but the potash is retained in the ashes."

Methods and interpretation of water analysis, A. ROBIN (*Amer. Jour. Pharm., 76 (1904), No. 3, pp. 101–116*).—This article refers to the unreliability of chemical data, and gives especial attention to methods of bacteriological examination, particularly the interpretation of results.

The technical analysis of water, W. E. RIDENOUR (*Amer. Jour. Pharm., 76 (1904), No. 3, pp. 121–125*).—A scheme of analysis of water for technical purposes is briefly described.

The separation of calcium and magnesium, C. STOLBERG (*Ztschr. Angew. Chem., 17 (1904), pp. 741–744, 769–771; abs. in Chem. Centbl., 1904, II, No. 2, p. 152*).—The separation is effected as follows: Convert into sulphates and dissolve the magnesium sulphate in water, add a mixture of methyl and ethyl alcohol (10 volume per cent of the latter), which throws all calcium sulphate out of solution, the latter being collected on a filter and weighed. Evaporate the alcoholic solution of magnesium sulphate and weigh the residue.

A eudiometric method for determining calcium, barium, strontium, and potassium, and eudiometric and gravimetric methods for copper, E. RIEGLER (*Ztschr. Analyt. Chem., 43 (1904), No. 4, pp. 205–214*).—The same principle on which the method for ammonia already noted (E. S. R., 15, p. 846) is based is utilized in these determinations, viz, the insolubility of the iodate of these elements in dilute alcohol and the evolution of nitrogen when they are treated with hydrazin sulphate. Tables for calculating the results from the volume of nitrogen evolved are given.

The detection of arsenic by biological means, W. HAUSMANN (*Beitr. Chem. Physiol. u. Pathol., 5 (1904), No. 7–8, pp. 397, 398*).—A summary of observations on the detection of arsenic by means of *Aitpasia diaphana*, together with references to the work of other investigators.

A short method of estimating glycogen quantitatively, E. PFLÜGER (*Arch. Physiol.* [*Pflüger*], *103 (1904), No. 3–4, pp. 169, 170*).—The method described consists in heating for 2 hours 100 gm. of finely divided material in 100 cc. of 60 per cent boiled potassium hydroxid solution, cooling, and diluting with 200 cc. sterilized water and 400 cc. of 96 per cent alcohol. After the suspended material has settled the solution is filtered and the precipitate washed with a mixture of 15 per cent potassium hydroxid solution and 96 per cent alcohol 1:2, and then with 66 per cent alcohol.

The precipitate (with the filter paper) is boiled in water and the solution neutralized. If a large amount of protein is separated a second filtration and boiling with water is necessary. Hydrochloric acid is added until the solution contains 2.2 per cent, and inverted for 3 hours. After cooling, neutralizing, and filtering the amount of sugar is estimated with a polariscope. The sugar value multiplied by the factor 0.927 gives the glycogen value.

Analyses of rocks from the laboratory of the United States Geological Survey, 1880 to 1903, F. W. CLARKE (*U. S. Geol. Survey Bul. 228, pp. 375*).—A revised edition of Bulletin 168, including nearly 300 new analyses. "In this edition the names are stated which the rocks would bear in the classification proposed in 1903 by Messrs. Cross, Iddings, Pirsson, and Washington, and set forth by Doctor Washington in Professional Paper No. 14. Mr. Clarke has also given a new computation of the average composition of rocks, closely agreeing with his former estimates, but founded upon more extensive data."

The measurement of ultramicroscopic particles with especial reference to colloid gold solutions and gold glass, H. SIEDENTOPF and R. ZSIGMONDY (*Ber. Deut. Phys. Gesell., 5 (1903), No. 11, pp. 209–216, fig. 1*).—The method of rendering visible and measuring ultramicroscopic particles has been noted from another publication (E. S. R., 16, p. 15).

Estimating the hydrothermal equivalent of a Berthelot bomb calorimeter in electrical units, W. JAEGER and H. VON STEINWEHR (*Ber. Deut. Phys. Gesell., 5 (1903), No. 2, pp. 50–59, figs. 3*).—A method of estimating the hydrothermal equivalent of the Berthelot bomb calorimeter is described, which the authors consider very accurate.

Platinum thermometers as a means of increasing the accuracy of calorimetric measurements, W. JAEGER and H. VON STEINWEHR (*Ber. Deut. Phys. Gesell., 5 (1903), No. 20, pp. 353–363, figs. 3*).—The platinum thermometer for use with the bomb calorimeter is described, which, according to the authors, makes for greater accuracy.

BOTANY.

The influence of current electricity on plant growth, G. E. STONE (*Massachusetts Sta. Rpt. 1903, pp. 13–30, figs. 2*).—After briefly describing some previous investigations on the subject, an account is given of some experiments conducted by the author under conditions resembling those which can be employed in commercial gardening. The work was carried on in a greenhouse with radishes and lettuce in boxes placed on movable trucks. The boxes were filled with a uniform quality of soil, were thoroughly insulated, and after using the soil for a few experiments it was resifted and used again.

With a few exceptions copper and zinc plates were used for electrodes, and the radish seed was sown directly in the boxes, whereas the lettuce was transplanted to

the boxes after the plants had attained a suitable size. Gravity cells were used in all cases except in experiments with the interrupted induced current, in which case sal-ammoniac cells were employed.

The different experiments are described at length, and with the radishes the results of treatment with various kinds and strengths of current are shown, 3,446 treated and 2,022 untreated radish plants being compared. The comparisons are based on the growth of the normal plants in each case and not on the total normal, since the duration of the different experiments did not entirely correspond. The results show appreciable gains and the percentages given represent a total gain for roots and tops of 27.34 per cent due to the influence of electric treatment. The growth of the tops showed a notable acceleration, being about 2.5 times as great as the increased growth shown by the roots.

The experiments with lettuce were somewhat similar in result, the increased growth being slightly higher than the average percentage given for radishes, although the acceleration was not as great as that shown in the growth of the radish tops over the roots.

The author concludes from the experiments that electricity has an accelerating effect on the growth of plants as shown by the positive results obtained in hundreds of experiments, and that the alternating current is much superior to the direct current as a stimulator of growth. A discussion is given of the manner in which electricity stimulates plants, a number of theories being presented.

The influence of the atmospherical electrical potential on plants, N. F. Monahan (*Massachusetts Sta. Rpt. 1903, pp. 31–36, fig. 1*).—A brief account is given of some preliminary experiments made to test the effect of atmospheric electrical potential on germination, growth, and development of plants. The experiments were conducted in large glass cases provided with doors fitted with rubber bands and closed so as to render them practically air-tight. The stands were insulated and arrangements made for determining the potential at any time. The cases in some instances were charged with Holtz induction machines and at other times from Leyden jars, and the growth of the plants was measured by a self-registering auxomete or by the use of horizontal microscopes.

Experiments were carried on with seeds of white clover, onion, lettuce, red clover, and muskmelon, and the effect on plant growth was studied with tomato plants, corn cotyledons, and a number of molds. It was found that the atmospheric electricity exerted a considerable influence on the germination of seeds, but did not increase to any appreciable degree the total germination, nor did it awaken the activity of seeds which had practically lost vitality due to age. Atmospheric electricity was shown to have an appreciable influence on the growth of plants, and it is believed that there is a maximum, minimum, and optimum potential which has not yet been determined. The voltage required for the maximum, optimum, and minimum is found to vary not only with different varieties or species of plants, but with different individuals of the same variety, depending upon the size, degree of development, etc.

The carbon nutrition of some plants by means of organic compounds, J. Laurent (*Rev. Gén. Bot., 16 (1904), Nos. 181, pp. 14–48; 182, pp. 66–80; 183, pp. 96–128; 184, pp. 155–166; 185, pp. 188–202; 186, pp. 231–241, pls. 7*).—After a historical summary of investigations relating to the possibility of chlorophyll-bearing plants assimilating carbon through their roots when grown in cultures containing organic compounds, the author gives the results of a prolonged series of experiments along this line. The plants experimented with were wheat, maize, buckwheat, peas, 2 varieties of beans, and the common groundsel.

In order to obtain comparable results and to eliminate a source of error, all the seeds were sterilized before germination and their roots were protected against infection by bacteria, molds, etc. The seedlings were grown in Knop's and Detmer's solutions to which were added definite quantities of glucose, soluble starch, dextrin, saccharose, glycerin, and humus compounds.

The results obtained show that glucose was readily absorbed through the maize roots with an increased growth and greater dry weight of the product. This took place whether plants were grown in light or darkness and also in the entire absence of carbon dioxid. Beets grown in the open air, when watered with glucose solutions, gave an increased dry weight as compared with others not so treated. The roots of maize and peas were found to take up soluble starch to some extent. The results with dextrin and saccharose were quite similar to those obtained with glucose. Glycerin was readily taken up by the roots of peas and lentils and transformed by the plants into reserve starch. It was less rapidly absorbed by maize roots. In the experiments with humus compounds maize took up as much as 10 per cent of its dry weight from potassium humate.

In the second part of the paper, the author discusses the influence of these carbohydrate compounds on the growth and morphological development of the plants, as well as the anatomical modifications induced in them. The effect of glucose, saccharose, and glycerin on the morphological and anatomical structure of plants was comparable in all cases where isotonic solutions were used. The author concludes with the generalization that all plants are able to secure their necessary carbon from certain organic compounds, chlorophyll and other pigment-bearing plants having in addition to this capacity the power of photosynthesis.

Investigations on the assimilation of some ternary compounds by plants, P. Mazé and A. Perrier (*Compt. Rend. Acad. Sci. Paris, 139 (1904), No. 9, pp. 470–473*).—The ability of the higher plants to assimilate carbohydrates other than through their leaves has been the subject of controversy for some time, and the author gives the results of investigations in which it is shown that vetch seedlings grown in the dark are able to take up sugar from solutions in a similar way as other nonchlorophyll-bearing plants. Experiments with maize seedlings gave similar results.

After germination, plants were grown in solutions which had added to them 1 per cent each of glucose, saccharose, mannite, glycerin, and ethyl and methyl alcohol. The seedlings cultivated in the light in the solutions containing ethyl alcohol did not show any appreciable increase in weight. In the methyl-alcohol solutions the plants grew rapidly at the beginning, making a more rapid growth than the check plants. Experiments with glycerin seemed to show that this substance exerted an injurious effect on vegetation. When the maize seedlings were cultivated in solutions to which were added glucose or saccharose, the growth was much more rapid than in the other medium.

The increase in weight of the plants and the decrease of glucose and saccharose in the different solutions are shown in tabular form, indicating that normal green plants are able to assimilate sugars the same as fungi and bacteria. One important difference which exists between them is that the chlorophyll-bearing plants are able to derive their carbon dioxid from the air, while among the fungi and bacteria so far only the nitrous and nitric ferments are able to draw their carbon from the carbonic acid of the air.

Sexual reproduction in the Mucorineæ, A. F. Blakeslee (*Proc. Amer. Acad. Arts and Sci., 40 (1904), No. 4, pp. 205–319, pls. 4, figs. 5*).—This contribution is a result of several years' investigations on the part of the author on this group of molds, and treats of the production of the so-called sexual spores or zygospores which are characteristic of this fungi. After giving a historical review of the theories relating to zygosporic reproduction of the Mucorineæ and citing species in which zygospores have been reported, the author describes his observations, dividing the group into 2 forms based upon the method of zygospore formation.

The production of zygospores is said to be primarily inherent with the individual species and is only secondarily influenced by external factors. In the homothallic group, which comprises the minority of species, the zygospores are developed from branches of the same thallus or mycelium, and can be obtained from the sowing of a

single spore. In the heterothallic group, which embraces a large majority of the species, the zygospores are developed from branches which belong to mycelia of diverse character and can never be obtained from the sowing of a single spore. Therefore, every heterothallic species is an aggregate of 2 distinct strains, and the sexual strains show generally a more or less marked differentiation in vegetative luxuriance, which is designated by the author for convenience by the use of the plus and minus signs. The development of these different strains and their relation to each other are discussed at considerable length.

Summarizing the observations, the author concludes that the formation of zygospores is a sexual process; that the mycelium of a homothallic species is bisexual, and of a heterothallic species unisexual, and that the plus and minus series of a heterothallic group represent the 2 sexes. A considerable bibliography of this subject concludes the contribution.

The anatomy of leaves of British grasses, L. Lewton-Brain (*Trans. Linn. Soc. Bot. [London], 2. ser., 6 (1904), No. 7, pp. 315–359, pls. 5; abs. in Bot. Centbl., 95 (1904), No. 25, p. 659*).—The object of this paper is to present by means of diagrams and descriptions of the transverse section of the leaf, material for the identification of grasses from their vegetative characters. The first part of the paper gives an account of the general anatomy and histology of the grass leaf, dealing in particular with the general outline of its transverse section, structure of epidermis, the mesophyll, vascular bundles, etc. In the second part of the contribution about 80 species of grasses are arranged according to an artificial key based upon the anatomical structures mentioned in the preceding part, while the third part of the paper discusses the leaf structure of the different grasses in relation to their habitat.

The influence of oxygen on chlorophyll production, J. Friedel (*Bul. Soc. Bot. France, 51 (1904), No. 2, pp. 100–103*).—In continuation of experiments on the effect of atmospheric pressure on chlorophyll production (E. S. R., 14, p. 653), the author has given the results of additional experiments with other plants which tend to confirm his previous conclusions. All the plants experimented with were grown under conditions in which the atmospheric pressure could be regulated and comparisons drawn between their growth in rarefied air, in atmospheres of oxygen of varying pressures, and under normal conditions. It was found that chlorophyll production is dependent upon the absolute amount of oxygen present and is independent of the total pressure of the gas.

Report of the botanists, G. E. Stone and N. F. Monahan (*Massachusetts Sta. Rpt. 1903, pp. 9–12*).—Brief summaries are given of the principal investigations carried on by the authors during the period covered by the report. The season is said to have been a peculiar one, and the absence of many common fungi is noted, while others of little serious importance were very prevalent. Brief notes are given on the occurrence of raspberry cane blight; an unusual leaf spot of corn caused by the fungus *Helminthosporium inconspicuum;* stem rots of carnations, asters, etc.; leaf spot of English ivy due to *Vermicularia trichella*, and a leaf blight of horse-chestnut due to *Phyllosticta sphæropsoidea*. Notes are also given on the winterkilling of a number of hitherto considered hardy plants and a brief statement made regarding the experiments conducted at the station on the effect of electricity on plant growth.

FERMENTATION—BACTERIOLOGY.

Report of the Agricultural Bacteriological Laboratory of the Ministry of Agriculture for 1901, A. Theoktistov (*Selsk. Khoz. i Lyesor., 211 (1903), Nos. 10, pp. 184–208; 11, pp. 285–316*).—Investigations pursued during the period covered by the report embrace the following: Bacteriological investigations of herring brine, virulence of bacteria which kill mice, fermentation of tobacco, lactic-acid investiga-

tions, pure cultures for Emmenthaler cheese, studies on properties of Russian export butter, laboratory work in zymology, the application in wine making of cultures of yeast, investigations of disease in faulty wines, selection and improvement of yeast, and instructions for the use of pure yeasts.—P. FIREMAN.

An experimental study of the chemical products of Bacillus coli communis and Bacillus lactis ærogenes, L. F. RETTGER (*Studies Rockefeller Inst. Med. Research, 1 (1904), Art. 11; reprinted from Amer. Jour. Physiol., 8 (1903), No. 4, pp. 284–293*).—A report is given of studies of the colon bacillus and the closely associated *B. lactis ærogenes*, to determine some of the chemical products of these organisms.

It was found that these organisms failed to bring about a very marked decomposition in peptone bouillon. On the other hand, an egg-meat mixture underwent rapid and extensive transformation. The common products of the colon bacillus were indol, skatol, phenols, aromatic oxy-acids, skatol-carbonic acid, hydrogen sulphid, mercaptan, tyrosin, leucin, and tryptophan. Albumoses and peptone were present in very small amounts, a fact which is contrary to general belief.

It is thought that probably the bacteria peptonize proteids, but that the albumoses and peptone formed are immediately broken up by the organisms or their enzyms, and are, therefore, detected with great difficulty. *B. coli communis* caused more rapid and profound decomposition than *B. lactis ærogenes*, the former producing its optimum results within 2 or 3 weeks, while for comparable results the second organism required from 8 to 10 weeks.

When bacterial digestion progressed beyond a certain point the intermediate products, such as peptone, amido acids, etc., gradually disappeared from the mixtures. Indol persisted for a longer time. The disappearance of the intermediate products is thought to be due to their further cleavage and the formation of still simpler bodies yielding ultimately carbon dioxid, methan, etc.

Studies of media for the quantitative estimation of bacteria in water and sewage, S. DE M. GAGE and G. O. ADAMS (*Reprinted from Jour. Infectious Diseases, 1 (1904), No. 2, pp. 358–377*).—Attention is called to the fact that the media in general use for quantitative work give inconstant results in determining the total number of bacteria in a given volume of water. In addition, different results are given for different classes of water, periods of incubation, etc. The authors present a number of facts having an important bearing on the composition and preparation of media which, if adopted, would probably serve as a basis for improvement and more accurate methods of quantitative bacterial analysis.

Results of the investigations on composition and preparation of different media are given. It is said that standard gelatin and agar beef broth are sources of considerable variation. The amount of nutrient matter in beef infusion made by the usual methods varies through wide limits. Of the 2 best commercial peptones, Merck's and Witte's, the higher bacterial counts were obtained on media made from the latter.

Studies made of plain agar with various kinds of natural water showed that, in a majority of cases, the bacteria naturally present in a given water will develop in greatest numbers in a medium made with the same water. Salts naturally present in commercial agar have a detrimental effect which may be overcome by washing out the salts in a preparation of the medium. Media made with glycerin will develop more bacteria than the same media without it. The pure cultures of different kinds of bacteria on standard gelatin, agar, or Nährstoff agar, the highest counts were obtained on gelatin and the lowest on Nährstoff. A reduction in the amount of Nährstoff in the Nährstoff agar from 1 per cent to 0.5 per cent resulted in a considerable increase in the number of bacteria observed in various waters. When cooked in alkaline solutions, the albumoses of Nährstoff undergo changes in composition which render them better food material for bacteria than is the case with the commercial product.

In studying the efficiency of waters in removing bacteria when efficiency is determined by the counts of different media, there was found to be a wide variation between the media used. With gelatin and Lawrence agar the ratio was less variable than between different lots of other media.

The writers are convinced that a uniform system of nomenclature should be adopted and the names applied to the various media should convey definite information as to their composition, method of preparation, etc.

The activity of bacteria in the soil, O. BAIL (*Sitzber. Deut. Naturw. Med. Ver. Böhmen, n. ser., 23 (1903), pp. 296–298*).—A popular account is given of the action of bacteria in soils, especial attention being given to the nitrogen-assimilating organisms.

The differential diagnosis of some pathogenic bacteria, OMYELYANSKI (*Arch. Biol. Sci.; abs. in Zhur. Opuitn. Agron.* [*Jour. Expt. Landw.*], *5 (1904), No. 2, pp. 288, 289*).—The author proposes the utilization of the increased alkalinity of the medium when bacteria are grown in it as a means of the differential diagnosis of species.

He introduces into the medium sodium formate and phenolphthalein. In the decomposition of the sodium formate, sodium carbonate is produced and the medium becomes more and more alkaline with the increased growth of the bacteria. Cultures of different species of bacteria display different rates and intensity of coloration, and it is believed that this may serve as a convenient method of recognizing species.—P. FIREMAN.

The nitrifying organisms in sewage filters, SCHULTZ-SCHULTZENSTEIN (*Tech. Quart., 17 (1904), No. 2, pp. 186–203*).—The results of a bacteriological study at the sewage-disposal works at Berlin are given. The organisms were isolated by the methods suggested by Winogradsky and their action studied, comparisons being made with the nitrifying organisms present in the soils of cultivated fields.

Nitrifying organisms were found present, and for their isolation the silica-jelly media of Winogradsky is strongly recommended. The organisms were introduced by the sewage into the filters, and they were also found present in Berlin spring water and tap water. No other nitrifying organisms than those described by Winogradsky were found on the coke of the biological filters. The action of the organisms on the sewage is described at length and notes given on some of their biological characteristics.

Notes on Saccharomyces anomalus, K. SAITO (*Jour. Col. Sci. Imp. Univ. Tokyo, 19 (1904), Art. 18, pp. 14, figs. 4*).—The author reports having isolated from sake mash the fungus *Saccharomyces anomalus*. The morphology and physiology of the yeast are described, its fermentation products and temperature relations being noted.

Notes on some ferments of diseased wines, P. MAZÉ and P. PACOTTET (*Ann. Inst. Pasteur, 18 (1904), No. 4, pp. 245–263, pl. 1*).—The results of a study of the ferments of spoiled wines begun in 1900 are given. About 20 species of bacteria were isolated and studied. These caused bitter wines, turned wines, broken wines, etc. The methods of isolation, cultivation, and the physiological characteristics of the different ferments are described. The causes of the presence of these organisms and the manner in which they bring about changes in wines are discussed.

The effect of certain poisons on inorganic ferments, C. JONES (*Chem. News, 1903, pp. 184–187; abs. in Bot. Centbl., 95 (1904), No. 22, pp. 582, 583*).—A review is given of the work of Bredig and von Berneck on the so-called inorganic ferments, which consist of finely divided metals, such as platinum, silver, gold, etc.

These form the so-called colloidal solutions which have the power of accelerating the oxidation of alcohol, decomposition of calcium formate, carbon dioxid, and hydrogen in the same manner as certain bacteria. They also cause the inversion of cane sugar and split up hydrogen peroxid into water and oxygen like certain ferments. Hydrocyanic acid, sulphuretted hydrogen, carbon monoxid, phosphorus, mercuric chlorid, etc., when supplied to colloidal solutions retard or prevent their action.

After standing some time the colloidal solutions recover from the inhibiting effect of hydrocyanic acid and some others, but from iodin compounds there appears to be no recovery. The action of these poisons toward the inorganic ferments is quite similar to that upon ferments in general.

The occurrence in fungi of ferments which break down amids, K. SHIBATA (*Beitr. Chem. Physiol. u. Pathol., 5 (1904), No. 7-8, pp. 384-394*).—Experiments are reported and discussed.

The formation of toxic products by vegetable enzyms, C. A. BROWNE, Jr. (*Science, n. ser., 20 (1904), No. 501, pp. 179-181*).—In the course of experiments with sugar cane the author reports having frequently observed that cane which had been sterilized by steaming suffered a more rapid deterioration through attacks of molds and bacteria than raw cane. Further, it has been observed that juice from the upper green portion of the living cane is more resistant to fermentation than juice from the riper joints further down. The juice from the top of the cane undergoes a rapid darkening after pressing, while that from the middle and bottom exhibits such a change to a much less degree, and the juice from steamed cane exhibits no change in coloration whatever.

The change in color is attributed to the action of the oxidizing enzyms, and that such bodies do occur in the sugar cane is readily shown. From the association of the coloration phenomena with resistance to fermentation, it is concluded that the dark-colored oxidation products produced by enzyms may have a toxic or germicidal action. That they do possess this characteristic is shown by experiments which are described at some length.

The endosperm enzym of the date palm, R. H. POND (*Science, n. ser., 20 (1904), No. 501, p. 181*).—A preliminary report is given of studies on the enzym found in the endosperm of the date-palm seed. The method of isolation and some of the characteristics of the enzym are described.

Micro-organisms of soil and human welfare, T. J. BURRILL (*Science, n. ser., 20 (1904), No. 509, pp. 426-434*).—In a presidential address read before the American Microscopical Society, the author calls attention to a number of species of soil bacteria which have an important bearing on the human race. Particular attention is paid to the nitrifying organisms and the tubercle bacteria.

The behavior of enzyms, especially chymosin, chymosinogen, and antichymosin toward concentrated electric light, S. SCHMIDT-NIELSEN (*Beitr. Chem. Physiol. u. Pathol., 5 (1904), No. 7-8, pp. 355-376, figs. 6*).—Experiments are reported and discussed. According to the author, strong light with a constant quantity of ultraviolet rays furnishes a new means for studying ferments.

ZOOLOGY.

Experiments with the infection method of Löffler for combating the mouse plague according to a new method of application, J. PFREIMBTNER (*Fühling's Landw. Ztg., 53 (1904), Nos. 16, pp. 619-627; 17, pp. 662-667*).—Attention is called to the great damage caused by field mice in various parts of Europe. In some years enormous losses are due to the attacks of these pests. In the author's opinion the infection method of Löffler will give good results in most cases when applied thoroughly and conscientiously. In some instances of failure it is believed the negative result was due to the use of material which contained no virulent culture of the organism. The contention that the organism of mouse typhus is identical with the paratyphoid bacillus of man is combated. It is argued that these organisms differ in biological relation and in their chemical reaction.

Plague of field mice in France, G. H. JACKSON (*Dept. Com. and Labor, Mo. Consular Rpts., 1904, No. 288, pp. 67, 68*).—Notes are given on the depredations com-

mitted, especially in southern France, by field mice. An account is presented of experiments in infecting mice over large areas of land. This method of destruction has been carried out systematically on an area of 2,800 acres and has proved successful, while the fowls and other farm animals did not become infected.

The extermination of rats, A. NEGREIROS (*Jour. Agr. Trop., 4 (1904), No. 33, pp. 76, 77*).—Attention is called to the great depredation of these animals, especially in St. Thomas, where they destroy a considerable portion of the cacao and some other crops. The virus prepared by Danysz for use in destroying these pests was tried with negative results. Attention will be given to a test of the method proposed by the Pasteur Institute.

The Parker rabbit exterminator (*Queensland Agr. Jour., 15 (1904), No. 2, pp. 613, 614, fig. 1*).—A description is given of a contrivance which has been devised and tested in the destruction of rabbits. The effectiveness of the device depends on the habit of rabbits in traveling along newly turned furrows. A small receptacle containing a quantity of fluid poison sufficient to kill about 300 rabbits is placed underground in the floor of the furrow. The weight of the rabbit upon a small platform attached to the apparatus is sufficient to discharge a certain quantity of the poison upon the fur of the rabbit through a small nozzle. The poison is mixed with some sugar in order to make a sticky fluid. The rabbits are poisoned when they lick this material from their fur.

Dingo trapping (*Jour. Dept. Agr. West. Australia, 10 (1904), No. 2, pp. 82–84, pl. 1*).—Notes are given on methods of placing traps so as to catch the dingo or wild dog of Australia. This animal commits considerable depredations upon sheep flocks and is so wary that special methods are required in trapping it successfully.

Importation of insectivorous birds, B. O. CLARK (*Hawaiian Forester and Agr., 1 (1904), No. 3, pp. 53, 54*).—The author refers briefly to the beneficial effects of certain birds on account of their feeding habits. It is recommended that Brewer's Blackbird, which is especially common in southern California and which shows more or less insectivorous habits, should be introduced for the purpose of combating the leaf hopper pests of sugar cane and other insects. As stated by another author, however, this bird frequently attacks grain crops, and the possibility of its being injurious to rice in Hawaii must be considered.

The sparrow plague and its remedy, A. BATHGATE (*Trans. and Proc. New Zealand Inst., 36 (1903), pp. 67–79*).—The literature relating to the English sparrow is critically reviewed. The bird is considered as doing far more harm than good, and the means for its destruction are therefore discussed. In combating the English sparrow the author believes that little hope is to be entertained from the method of offering bounties. The 2 methods recommended are systematic trapping by expert bird catchers and the introduction and encouragement of the natural enemies of the English sparrows, such as owls, jays, magpies, shrikes, and other birds. Under the exercise of proper precautions poisoning may also be effective.

The birds of Erie and Presque Isle, Erie County, Pennsylvania, W. E. C. TODD (*Ann. Carnegie Mus., 2 (1904), No. 4, pp. 481–596, pls. 4*).—A study was made of the bird fauna in the northwestern portion of the State of Pennsylvania, particularly about the town of Erie and on Presque Isle. The chief purpose of this study was to determine the number of species present, their distribution, and the influence of Lake Erie and local conditions upon this distribution. Notes are given on the frequency of occurrence and other biological data concerning all species which are reported.

The marsh hawk and its beneficial effects in the destruction of mice (*Com. Parasit. Agr. [Mexico], Circ. 10, pp. 5, fig. 1*).—Brief notes on the feeding habits and economic importance of this bird.

Sawdust and fish life, A. P. KNIGHT (*Trans. Canad. Inst., 7 (1904), III, No. 15, pp. 425–466, figs. 6*).—On account of the abundant occurrence of sawdust in streams,

the author has been led to investigate the effect of its occurrence on fish life. Numerous experiments were conducted with various kinds of sawdust in aquaria where the conditions could be controlled, and it was found that strong sawdust solutions at the bottom of an aquarium poisoned fish through the agency of compounds dissolved from the wood cells. The overlying water in such an aquarium did not at first kill fish, but after about a week it would do so, the dissolved oxygen having been exhausted.

Bacteria were found to multiply enormously through all parts of the aquarium, and through oxidation changed the poisonous extracts to harmless compounds. Subsequent aëration and sedimentation of sawdust water purifies it so that fish can live in it without injury. It was found that adult fish, as well as black bass fry, refused to be driven into pine extracts in the bottom of the aquarium after they had experienced its poisonous effects, and from this it is inferred that fish would desert a river polluted with such sawdust.

The author states that no stream can be pronounced offhand as poisoned by sawdust, but each must be studied by itself. The chief things to be considered are the quantity of the sawdust and the volume of water into which the sawdust is discharged.

A fish which attacks cows, A. MIRANDA (*Jour. Agr. Trop., 4 (1904), No. 38, pp. 235, 236*).—The fish belonging to the species *Serrasalmo piraya* occurs very abundantly in parts of the Amazon, and during flood time is found in great numbers in the shallow overflow water. When cows stand in such water during the heat of the day they are attacked upon the legs and udder by the fish. Great injury is done to these parts, and in many cases cows are rendered useless for dairy purposes or are killed outright. In one instance a dairyman lost 400 cows from this cause in a single season.

Zoological yearbook for 1903, P. MAYER (*Zool. Jahresber., 1903, pp. VIII+596*).—This report contains short abstracts of the more important investigations published during the year on the various groups of the animal kingdom. Extensive bibliographies are given in connection with each group of animals.

[Monthly bulletin of the division of zoology], H. A. SURFACE (*Pennsylvania State Dept. Agr., Mo. Bul. Div. Zool., 2 (1904), No. 6, pp. 164–192, figs. 4*).—Brief notes are given on collecting insects, spraying trees, treatment for peach-tree borers and the San José scale, nature study, game laws, and robins.

Annual report of the division of zoology, H. A. SURFACE (*Pennsylvania State Dept. Agr. Rpt. 1903, pp. 159–191*).—Notes are given on the equipment, investigations, collections, and publications of this division, together with a brief review of economic zoology in Pennsylvania and a report upon nursery inspection in the State.

METEOROLOGY—CLIMATOLOGY.

Report of the Chief of the Weather Bureau, 1902–3 (*U. S. Dept. Agr., Weather Bureau Rpt. 1902–3, pp. XLIII+308*).—The first part of this report contains an account of the operations of the Weather Bureau during the year; part 2, a list of observing stations and changes therein during 1902, and hourly averages of atmospheric pressure, temperature, and wind from the records of automatic instruments at 28 stations; part 3, monthly and annual meteorological summaries for 165 Weather Bureau stations; part 4, monthly and annual means and extremes of temperature and dates of first and last killing frosts, 1902; part 5, monthly and annual precipitation, 1902; and part 6, miscellaneous meteorological tables and reports.

Observations and investigations made at the Blue Hill Meteorological Observatory, Massachusetts, U. S. A., in the years 1901 and 1902, A. L. ROTCH (*Ann. Astron. Obs. Harvard College, 43 (1903), pt. 3, pp. 115–239, pls. 4; rev. in Science, n. ser., 20 (1904), No. 503, pp. 240, 241*).—This is a report dealing with addi-

tions to equipment, kite observations on land and sea, with descriptions of kites and instruments used in exploration of the air, and studies of the effect of meteorological conditions on audibility.

Climate: Its physical basis and controlling factors, W. L. MOORE (*U. S. Dept. Agr., Weather Bureau Bul. 34, pp. 19, fig. 1*).—A reprint of an article prepared for Encyclopedia Americana.

Smoke as a preventive of frost, T. HAYNES (*U. S. Dept. Com. and Labor, Mo. Consular Rpts., 75 (1904), No. 285, p. 1040*).—A brief note on successful experiments in France in preventing frost in vineyards by means of smudges, especially those produced by burning gas tar.

Annual precipitation in Oklahoma, C. M. STRONG (*Oklahoma Sta. Rpt. 1904, p. 63*).—A summary of all available data for annual precipitation during the period 1889–1903 at 25 places in the State.

SOILS.

Some observations on the "ortstein" formations of southern Russia, V. N. SUKACHEV (*Pochvovyedenie [Pédologie], 5 (1903), pp. 213–220; abs. in Zhur. Opuitn. Agron. [Jour. Expt. Landw.], 5 (1904), No. 1, p. 77*).—The author describes "ortstein" formations observed by him at 6 places in the Kharkov and Kursk governments. The fact of the occurrence of "ortstein" in those localities shows, according to the author, that for its formation an abundance of water is not necessary, the humidity which is found in the forest soils of the steppes being sufficient.

In all places where "ortstein" was observed the soils appeared to have been leached out and had been covered by woods, probably oak, while the subsoils were to a great extent sandy. Thus the processes of "ortstein" formation were here favored by the sandy nature of the soil and the oak forests, the latter yielding a litter rich in tannic acid. The mere presence of "ortstein," in the absence of all other soil characteristics, is, according to the author, a sure indication of the existence of woods.—P. FIREMAN.

Laterites and red soils of tropical and subtropical latitudes and allied soils of temperate latitudes, K. D. GLINKA (*Pochvovyedenie [Pédologie], 5 (1903), No. 3, pp. 235–264; abs. in Zhur. Opuitn. Agron. [Jour. Expt. Landw.], 5 (1904), No. 2, p. 241*).—The author discusses the occurrence of laterites under evergreen forests and savannahs, the formation, composition, and structure of such soils, and the changes which they undergo under different conditions of climate, etc. To the article is appended a list of 50 titles not included in the bibliography of Dubois on this subject.—P. FIREMAN.

The useful properties of clays, A. S. CUSHMAN (*U. S. Dept. Agr., Bureau of Chemistry Circ. 17, pp. 12*).—This circular discusses the formation of clays, and the production and importation of clays, and describes the kinds and physical properties of clays, including plasticity, binding power (tensile strength), slaking, air shrinkage, firing qualities (distortion, fusibility, and color), and absorptiveness. Notes are also given on the various uses of clays and on testing and examination of clays.

The humus calcareous soils (rendzinas) of the Vistula region, J. MASANOVSKI (*Zhur. Opuitn. Agron. [Jour. Expt. Landw.], 4 (1903), No. 5, pp. 528–545*).—This article presents a survey of the literature on a kind of soil very widely distributed in Poland and known there under the names of "rendzina" and "borovina." These soils have been formed on rocks rich in lime, e. g., on limestones and marls, with the simultaneous action of leaf-bearing forests. They are rich in humus (3 to 8 per cent), in most cases very heavy, but very fertile. They are best adapted to the cultivation of wheat and barley.—P. FIREMAN.

The effect of the long-continued use of sodium nitrate on the constitution of the soils, A. D. HALL (*Jour. Chem. Soc. [London], 85 (1904), No. 501, pp. 964–971*).—"By the mechanical analysis of soils from the five experimental fields at

Rothamsted, on which there are plats manured with sodium nitrate, it is found that the soil of these plats generally contains a lower proportion of the finest 'klay' fraction than does the soil of adjoining plats which have been either unmanured or have received ammonium salts in place of sodium nitrate. This result was most manifest in the mangel field where cultivation is frequent, and was not apparent at all in the grass field where the turf protects the soil from the washing action of the rain.

"The removal of the finest particles from the surface soil is attributed to deflocculation induced by the use of sodium nitrate, and followed by the washing of the finest particles into the subsoil. This hypothesis is confirmed by chemical analyses of the 'klays' separated in the mechanical analysis, by the examination of some of the subsoils, which are found to be richer in fine particles beneath the soils receiving nitrate, and by the condition of the soils in the field, which show every evidence of deflocculation."

Soil fertility in the light of recent investigations, S. BOGDANOV (*Selsk. Khoz. i Lyesov., 211 (1903), Nov., pp. 249–284*).—The author reviews the work of Dyer (E. S. R., 5, p. 1013) on acidity of root juices; of Prianishnikov, Kossovich, and Shulov (E. S. R., 13, pp. 235, 934; 14, pp. 343, 427) on the assimilation of the phosphoric acid of raw phosphates by different plants; of Schloesing and Paturel (E. S. R., 13, p. 1029; 14, pp. 127, 233, 341; 15, p. 760) on the phosphoric acid of soil solutions; of Fesca[a] on the solubility of soil constituents in water; of Czapek and Kohn[b] on root secretions; and others, in so far as these investigations relate to the alleged power of plants to assimilate difficultly soluble soil constituents by means of acid secretion of their roots.

He reaches the conclusion that in the strict sense there are no root secretions either acid or alkaline, but that plant roots in taking up the necessary constituents exercise a selective influence on the soil solution which varies with different plants and stages of growth and with the character of the soil. The plants undoubtedly play a part in dissolving substances from the soil, but this consists mainly in selecting the needed plant food from the soil solutions, thus helping the soil water to dissolve new quantities of nutritive substances. The physiological residues of the salts utilized by the plants may play a part, dependent upon the needs of the plants for nutritive substances and upon the chemical peculiarities of the soil. A part may also be played by the carbon dioxid which is exhaled by the roots of different plants in varying amounts.

It is pointed out, however, that the physiological residues of the salts, as well as the carbon dioxid exhaled by the roots, may be of importance only in the artificial conditions found in most experiments, especially such as prevail in sand cultures. In normal soils there are usually present plenty of substances which rapidly neutralize the physiological residues, and, since carbon dioxid is formed in normal soils in abundance at the expense of decomposing organic substances, the additional carbonic acid exhaled by the roots can scarcely be of much consequence.—P. FIREMAN.

Investigation of some chemical and physical properties of the separate products of the mechanical analysis of podzol and loess, D. P. MAZURENKO (*Inaug. Diss., Munich; abs. in Zhur. Opuitn. Agron.* [*Jour. Expt. Landw.*], *5 (1904), No. 1, pp. 73–75*).—The author employed the Fadyeyev-Williams method of mechanical analysis and operated on a rather large scale in order to obtain each fraction in sufficient quantity. The experiments were made with two strikingly different soils, a loess from the basin of the Donetz River and a podzol from the farm of the Moscow Agricultural Institute.

---

[a] Jour. Landw., 1873, p. 459; Jahresber. Agr. Chem., 16–17, 1873–74, p. 126.

[b] Jahresber. Wiss. Bot., 29 (1896), p. 321; Landw. Vers. Stat., 52 (1899), pp. 315-326.

The data regarding the chemical composition show that in the mechanical fractions of both the loess and podzol the amount of silica decreased and the other chemical constituents (alumina, ferric oxid, lime, magnesia, etc.) increased as the size of the particles decreased. The data further showed that all the mechanical products of the loess were richer as regards chemical composition than the corresponding products of the podzol, which fact is the more important as the quantity of the very small particles in the loess (24.85 per cent) considerably exceeds that in the podzol (3 to 5 per cent).

The specific gravity of the loess itself and of its mechanical fractions is greater than in the case of podzol. In both the soils the specific gravity of the mechanical fractions increased as the size of the particles decreased. To gain an idea of the volume-weight, compactness, and porosity, the author made briquettes from the separate mechanical fractions which were weighed and measured before and after drying. It was found that as the size of the particles decreased the quantity of the water evaporated from the briquettes increased, while the volume diminished, the decrease in volume being greatest in the products of the loess. The data showed that the volume-weight of the mechanical fractions of the loess increased as the size of the particles diminished, while in those of the podzol the contrary holds, except in the case of the finest particles (clay). The loess and its mechanical products showed a larger volume-weight than the podzol and its products. The porosity of the separate mechanical products was inversely as their volume-weights. Thus, in the loess the porosity diminished with the decrease in the size of the particles, while in the podzol it increased with the decrease in the size of the particles down to the finest particles, which showed a small relative porosity.

These differences in the properties of the mechanical fractions of the loess and podzol are accounted for, in the opinion of the author, by the difference in the form of the particles. In the loess and its mechanical products flat and scaly particles predominate, while in the podzol and its mechanical products, the clay excepted, spherical particles of quartz predominate. Flat particles are more easily wetted and possess a greater power of cohesion, thus causing greater compactness (volume-weight) and less porosity.—P. FIREMAN.

Experiments on the relative fertility of soil particles of different grades, D. L. RUDZINSKI (*Izv. Moscow Selsk. Khoz. Inst.* [*Ann. Inst. Agron. Moscow*], *9* (*1903*), *No. 2, pp. 172–234, pls. 5*).—The author prepared large quantities of the different sizes of soil particles for use in his experiments by means of the Fadyeyev-Williams method, which is as follows:

One kilogram of the air-dry soil is sifted through a sieve with holes 3 mm. in diameter. The lumps which do not pass through the sieve are disintegrated by rubbing in a mortar with a rubber-tipped or wooden pestle and again sifted. From the part of the soil which contains no particles larger than 3 mm. an average sample weighing 100 gm. is selected, while the part remaining on the sieve is freed from the finer grains clinging to it by boiling with water in a dish and then washing with pure water. The washed coarse grains are dried, sorted by sieves with holes of 10 and 5 mm. in diameter, and weighed.

A part of the sample, with particles not exceeding 3 mm. in diameter, is boiled with water for 6 hours in an enameled iron dish covered with a watch glass, allowed to cool, and washed into a sieve with holes 0.25 mm. in diameter placed in a large porcelain dish. The particles remaining on the sieve after pressing with a rubber-tipped glass rod and washing, are dried at 100 to 110°, again sifted, and then sorted by means of 1 mm. and 0.5 mm. sieves into 3 grades: Coarse sand with particles 1 to 3 mm., medium sand, 1 to 0.5 mm., and fine sand, 0.5 to 0.25 mm. in diameter. Each of the grades is dried at 100 to 110° and weighed.

Those particles of the soil which passed through the sieve with holes 0.25 mm. in diameter and were collected in a porcelain dish are allowed to settle during 5 minutes in a layer of water 10 cm. in height, as follows: The contents of the dish are transferred, in successive portions, to a beaker of 200 to 250 cm. capacity, which is provided with a mark 10 cm. from the bottom. The beaker is each time filled to the mark, the particles allowed to settle during 5 minutes, when the particles which have not settled are decanted into a glass dish with vertical walls, of 3 to 3.5 liters capacity (also provided with a mark 10 cm. from the bottom). The particles which settle at the bottom of the beaker have a diameter 0.25 to 0.01 mm. On drying the particles 0.25 to 0.05 mm. in diameter can be separated from those 0.05 to 0.01 mm. in diameter by Schöne's apparatus, so regulating the stream of water that its velocity in the cylindrical part of the funnel-shaped vessel is equal to 2.11 mm. a minute.

The liquid with the suspended particles obtained by pouring off after 5 minutes settling is allowed to stand in the glass dish during 24 hours. The particles which remain suspended (less than 0.001 mm. in diameter) are siphoned off into a tall glass cylinder with a capacity of 8 liters. The residue in the dish is once more stirred up with water added to the mark and again allowed to settle and the supernatant liquid decanted.

To insure a complete separation of the very fine particles it is sometimes necessary to boil the residue remaining in the glass dish with water for 12 hours, using for this purpose an enameled iron dish. In that case the contents of the iron dish after digestion are passed through a sieve with holes 0.25 mm. in diameter, in order to break the aggregates which sometimes form in boiling, into a glass dish with a mark, like the one mentioned above, but of less capacity.

After standing 6 hours the coarsest particles settle at the bottom of the glass dish while the finer particles, with an admixture of fine silt, remain suspended. The suspended particles are siphoned off into another dish and allowed to settle during 24 hours. The turbid liquid containing the fine silt is siphoned into the tall cylinder which already contains the main bulk of the silt of the sample. The coarser particles in the 2 dishes are treated with successive portions of water until the liquid above them, after settling, contains little suspended matter. The sediments thus obtained are then transferred with the aid of small quantities of water into beakers, 1 to 2 cc. of a saturated solution of calcium chlorid are added, and when the solutions above the residues have become clear the latter are filtered through weighed filters. The washing to remove the calcium chlorid adhering to the residues is continued until the filtrate begins to pass through turbid. The residues are then dried at 100 to 110° and weighed.

Finally the liquid in the tall cylinder containing the silt is treated as follows: After a considerable quantity of the liquid has been transferred from the dishes into the cylinder 20 to 25 cc. of a saturated solution of calcium chlorid are added, the liquid is stirred up and allowed to stand for some days until the silt settles at the bottom and the supernatant liquid becomes clear. The clear solution is siphoned off and fresh portions of the liquid, from the dishes, containing silt are transferred to the tall cylinder and treated in the same way. The silt, upon removal of the clear solution, is, as was the case with the coarser particles, washed with the aid of a little water into a beaker, treated with 1 to 2 cc. calcium chlorid, filtered through a weighed filter, dried, and weighed.

In obtaining the mechanical constituents of the soil for his experiments the author had to avoid the operation of boiling since he found that plants develop better on soils which were subjected to boiling for 6 hours than on the same soils not so treated. In order to disintegrate the small lumps he poured the particles of the soils which passed a sieve with holes 3 mm. in diameter into a Schöne apparatus filled with 300 cc. of water and agitated them by sucking air through the apparatus. Passing the

current of air during 4 hours was sufficient for complete disintegration of the various soils with which the author experimented. After the agitation by the current the liquid, together with the sediment, was brought into a sieve with holes 0.25 mm. in diameter, where the sandy part of the soil was separated. The further treatment of the soil was according to the Williams method.

In the author's experiments oats were raised in 5 kg. pots filled with a mixture of sterile sand and soil particles of different sizes prepared by the method described. In the first series the mixture consisted of the sand and so much of the mechanical element (silt, fine dust, medium dust, large dust, together with the sandy dust) as was obtained from 2 kg. of the soil. In the second series of experiments the necessary quantity of sand was mixed with normal soil and with the same deprived of one or more of the mechanical grades of particles. In both series of experiments the soils used were a clayey chernozem and a peaty clay. The third series of experiments was carried out with equal quantities of the different mechanical elements (each vessel receiving 250 gm. of the element in question and 4,500 gm. of sand). Parallel experiments in the case of each element were carried out with nitrogen and potash and with nitrogen and phosphoric acid.

In this series of experiments as well as in the following series the mechanical elements of the upper layer of a podzol soil and of the parent rock under it were investigated. The phosphoric acid and the potash in the silt and coarser particles, and the nitrogen, phosphoric acid, and potash in the crops of oats obtained were determined. In the fourth series of experiments sand and such amounts of the corresponding element were used that in the pots fertilized with nitrogen and potash the phosphoric acid amounted to 0.25 gm., and in the pots fertilized with nitrogen and phosphoric acid the potash content also amounted to 0.25 gm.

The following are some of the conclusions drawn: (1) The total contents of potash, phosphoric acid, and nitrogen in the mechanical elements of the soils investigated decreases with the increase of their size; (2) assimilable substances for the plants are contained not only in the silt, but also in the coarser grades; (3) since the very fine particles are present in the majority of soils in small quantities the fertility of soils depends largely upon the coarser particles; (4) the mechanical elements even of soils of a like geological origin are unlike in their chemical composition and in the availability of their plant food; hence it is impossible to judge of the fertility of a soil from its mechanical composition.—P. FIREMAN.

The mechanical analysis of soils and the composition of the fractions resulting therefrom, A. D. HALL (*Jour. Chem. Soc.* [*London*], *85* (*1904*), *No. 501*, *pp. 950–963*).—The author investigated the effect on the mechanical analysis of soils of the preliminary treatment with dilute acid followed by ammonia, proposed by Schloesing.

For the separation into fractions, Osborne's method of sedimentation was adopted, the soil being separated into two fractions by sieving and into five by sedimentation. He found that the raw soil rarely yielded as much of the finest fraction, for which the name "klay" is proposed, as was given by the same soil after washing with acid, the difference being greatest with soils rich in humus, the reason probably being that the humates, which act as a weak binding material, are decomposed by this treatment. Soluble salts, which might interfere, are also removed.

The difference shown by the two methods, however, practically disappears when the soil has long remained unmanured or has been deflocculated by the continued use of saline fertilizers. The Schloesing method consequently reveals the original character of the soil, irrespective of its manuring.

Investigations on the absorbent power of cultivated soils, C. DUSSERRE and T. BIELER (*Ann. Agr. Suisse*, *5* (*1904*), *No. 3*, *pp. 110–119*, *figs. 6*).—The history of the study of this property of soils from the time of its discovery by J. Gazzeri in

1819 is briefly reviewed, and experiments in glass cylinders filled with successive layers of fine soil (1 mm. particles) separated by filter paper to test the rate of absorption and depth of penetration of phosphoric acid in superphosphate solution, and potash in chlorid solution, are reported. The surface of the soil in the glass cylinders was covered with a filter paper and the solutions were poured on slowly, followed by distilled water, until a given amount had run out through the tube at the bottom of the cylinder.

After a period of a month the successive layers of soil were removed, dried, and analyzed. In the experiments three soils—siliceous clay, calcareous clay, and peat—were used. Phosphoric acid was applied at the rate of 3,410 kg. per hectare, the potash at the rate of 2,050 kg. per hectare. The phosphoric acid descended to a greater depth and a larger amount passed through in case of the peat than in case of the other soils, the siliceous clay standing next in these respects and calcareous clay last. In the latter all of the phosphoric acid was retained comparatively near the surface and none passed through.

The potash was more uniformly distributed through the different layers of the soils and in case of peat was to a large extent removed by repeated washing.

The results indicate in general that 96.6 per cent of the phosphoric acid and 72 per cent of the potash applied on the surface of soils is rendered insoluble before a depth of 8 cm. is reached.

Influence of the humidity of the soil at various periods of development of buckwheat on the yield of grain, I. A. PULMAN (*Zhur. Opuitn. Agron. [Jour. Expt. Landw.], 5 (1904), No. 1, pp. 68–72*).—Phenological observations by the author on the growth of buckwheat during 20 years have led to the conclusion that good yields of grain were obtained only when there was a sufficient rainfall during the period between blossoming and fruit forming.

To test the validity of this conclusion he made the following vegetation experiments in 1903: Four pots were used and in all the optimum humidity, 34 per cent, was at first maintained. The buckwheat plants (six in each pot) developed uniformly until the period of blossoming, at the beginning of which the humidity in one pair of the pots was maintained as before at 34 per cent, while in the other it was reduced to 24 per cent. As soon as the seed began to form, the humidity content was again altered; in one pot of the pair with 34 per cent the humidity was reduced to 24 per cent, while in one vessel of the pair with 24 per cent the humidity was raised again to 34 per cent.

The larger total yield and the greater number of good seeds were obtained where the abundant supply of water was maintained, and in the author's opinion furnishes a complete corroboration of his conclusion that for the yield of buckwheat seed the humidity of the soil during fruit-building is of primary importance.—P. FIREMAN.

On the moisture of the soil, N. A. DIMO (*Pochrovyedenie [Pédologie], 6 (1904), No. 1, pp. 45–58*).—Observations were made by the author simultaneously on meadow and forest soils of the same character, viz, heavy clay alluvium which becomes more friable at a depth of 65 to 85 cm. and then passes into a yellowish-white river sand. The surface is quite level, and the underground waters are rather near the surface.

Twenty-eight observations made during a period of 103 days (from May 21 to September 1) at depths varying from 10 to 140 cm. are reported. The mean percentages of moisture to a depth of 25 cm. was in meadow soil 18.32 per cent, in wood soil 21.51; in the soil layer at depths of 50 to 140 cm., 18.63 in meadow soil, 14.29 in forest soil; the average for all depths 18.53 in meadow soil, 17.30 in forest soil.

From these data the author concludes that (1) the mean values of the moisture of the soil for the entire depth and during the whole period are very close for both the meadow and the woods soil; (2) the surface layer from 0 to 25 cm. is more moist in the woods than in the meadow; (3) the deep layers, on the contrary, are more moist

on the meadow. Other observations indicated that the ground water level was reached in the meadow soil at a depth of 140 cm., but was lower in the woods soil.—P. FIREMAN.

Alkali and the treatment of alkali lands, J. S. BURD (*Idaho Sta. Bul. 44, pp. 355–367*).—A popular compilation of information on this subject preliminary to an alkali survey of the State.

FERTILIZERS.

The fertilizing value of human excrement, J. SEBELIEN (*Jour. Landw., 52 (1904), No. 3, pp. 291–300, pl. 1*).—An account is here given of pot experiments during 1902 and 1903 on oats grown in soil containing very little humus and nitrogen. In one series of experiments solid excrement, mixed with ground peat and kept for a few weeks before application, was used. In another series, urine, which had been kept for a few weeks and allowed to ferment, was experimented with.

The results of the 2 years' experiments on the same soil show that while the urine showed little fertilizing value, the solid excrement was more effective than nitrate of soda alone, thus demonstrating not only a high efficiency for the nitrogen, but also that feces are of considerable value as a source of phosphoric acid (and possibly of potash). The solid excrement was much more effective than the manure of ordinary domestic animals.

On an improved method of producing concentrated manure from human refuse, T. MACFARLANE (*Proc. and Trans. Roy. Soc. Canada, 2. ser., 8 (1902), Sec. III, pp. 87–95, dgm. 1*).—A closet of special construction in which dried peat moss is used as an absorbent is described and the fertilizing value of the product obtained by repeated use of the moss and the dried mixture of moss and excrement is discussed. By the method described a minimum amount of absorbent (not more than one-twentieth of the resulting manure) is used and a product obtained, one sample of which, in the air-dry condition, contained 3.16 per cent of nitrogen (2.42 per cent as ammonia), 2.52 per cent of phosphoric acid, and 0.65 per cent of potash. With the addition of preservative substances—superphosphate, sulphate of potash, and gypsum—products of still higher fertilizing value were obtained.

Salt as a garden fertilizer, GIERSBERG (*Deut. Landw. Presse, 31 (1904), No. 54, p. 482; Jour. Agr. Prat., n. ser., 8 (1904), No. 28, pp. 37, 38*).—This is a brief discussion of the value and use of salt as a fertilizer for vegetables and fruits, in which it is shown that this substance has a certain indirect effect in improving the quality of such crops. The maximum amount recommended for fruit trees is ⅓ to ½ lb. per tree, according to size, and for vegetables 150 to 200 lbs. per acre.

Analyses of commercial fertilizers, H. J. WHEELER, B. L. HARTWELL, and J. W. KELLOGG (*Rhode Island Sta. Bul. 101, pp. 151–160*).—"This bulletin contains the analyses of such of the commercial fertilizers found on sale in Rhode Island in 1904 as were branded especially for potatoes and vegetables. It also contains analyses of samples of bone, tankage, muriate of potash, and nitrate of soda," and notes on valuation.

Report on official inspection of commercial fertilizers and agricultural chemicals during the season of 1903, C. A. GOESSMANN (*Massachusetts Sta. Rpt. 1903, pp. 87–97*).—A brief summary of the work of the year, containing a table showing the average composition of the fertilizers examined and a list of licensed dealers in fertilizers.

Fertilizer inspection, C. D. WOODS and J. M. BARTLETT (*Maine Sta. Bul. 105, pp. 101–112*).—"This bulletin contains the analyses of samples collected by the station of the brands of fertilizers licensed in 1904."

FIELD CROPS.

Report of the agriculturists, W. P. Brooks and F. R. Church (*Massachusetts Sta. Rpt. 1903, pp. 110–149*).—The work here reported is in continuation of fertilizer experiments with field and garden crops previously undertaken (E. S. R., 15, p. 139). The year's work is briefly described, and the results obtained in the different tests are reported in detail. The more important conclusions are here summarized.

Soy beans were grown in connection with the comparison of different substances as sources of nitrogen. Nitrate of soda ranked relatively lower this year than in most previous years. As compared with the no-nitrogen plats, the various substances, based on the results of this season, ranked in the following order: Barnyard manure, nitrate of soda, dried blood, and sulphate of ammonia. The general average to date, based on the increase over the no-nitrogen plats, ranks the materials as follows: Nitrate of soda, 100; barnyard manure, 77.8; dried blood, 65.1, and sulphate of ammonia, 63.6.

The results of the year indicate that high-grade sulphate of potash is superior to muriate of potash for potatoes. The two salts gave practically equal yields when used for soy beans. An untoward season vitiated the results with cabbages and onions.

For the last 6 years nitrate of soda, sulphate of ammonia, and dried blood, in amounts furnishing 60 lbs. of nitrogen per acre, have been used in addition to 30 tons of barnyard manure per acre as applications for garden crops. For the early crops, including dandelions, strawberries, peas, and beets, dried blood ranked first, nitrate of soda second, and sulphate of ammonia third; while for the late crops, including late cabbages, turnips, celery, tomatoes, and squashes, nitrate of soda ranked first, dried blood next, and sulphate of ammonia last. Sulphate and muriate of potash were tested in connection with the applications just described, and the results for the year indicated the sulphate to be better for strawberries, tomatoes, cucumbers, celery, and turnips, while the muriate gave slightly better results with dandelions, peas, and beets.

The following potash salts, in applications supplying 165 lbs. of actual potash per acre, were tested on clover mixed with timothy: High-grade sulphate, low-grade sulphate, kainit, muriate, nitrate, carbonate, and silicate. The high-grade sulphate gave the best yields of clover, being closely followed by the silicate, carbonate, low-grade sulphate, and nitrate. The heaviest timothy was produced by the kainit and muriate. The potash salts containing chlorin, especially kainit, were injurious to the clover.

Different phosphates applied in amounts giving 96 lbs. of actual potash per acre were used this year in growing cabbages. Those giving satisfactory results ranked as follows: Dissolved bone meal, South Carolina rock phosphate, raw bone meal, phosphatic slag, steamed bone meal, and dissolved boneblack. Tennessee phosphate, apatite, and Florida soft phosphate proved much inferior to all others.

The season was unfavorable to the soil test with corn, but the results showed that potash gave a much greater increase in crop than any other plant-food element. The results of a soil test with mixed grass and clover demonstrated the need of nitrate of soda for grass, and also indicated a strong tendency to render the soil acid by the continued use of nitrate of soda and muriate of potash. In this experiment lime produced a marked result in increasing the proportion of timothy in a mixture of timothy, redtop, and clover.

Grass plats receiving the first year 8 tons of barnyard manure per acre, the second year 1 ton of wood ashes, and the third 600 lbs. of ground bone and 200 lbs. of muriate of potash as a fertilizer rotation gave this year an average yield of 8,104 lbs. of hay per acre in 2 crops. A portion of the field reseeded last year yielded 8,546.5 lbs., as compared with 6,243 lbs. for the portion not reseeded. On one plat reseeding

almost doubled the yield of hay. The average yield of the field since 1893 is 6,597 lbs. of hay per acre; and the average yield when top-dressed with manure 6,827 lbs.; with wood ashes, 6,427 lbs.; and with bone and potash, 6,562 lbs.

Winter and spring applications of barnyard manure were again compared, with the advantage slightly in favor of the winter application. This result is considered due to the ground remaining unfrozen under the snow, and that there was practically no wash over the surface.

Annual report of the Dumraon Experimental Farm for the year 1902-3, D. N. MOOKERJI (*Dept. Land Records and Agr., Bengal, Ann. Rpt. Dumraon Expt. Farm 1902-3, pp. 9*).—A brief historical note on the farm is given, and analyses of the surface and subsoil of the farm and a statement showing the distribution of rainfall for the year are presented. The results of different experiments are briefly reported.

Fertilizer experiments were conducted to ascertain the relative merits of different fertilizers on paddy, wheat, and sugar cane. The best yield of paddy was obtained from the use of 19 maunds[a] of cow manure and 4 maunds of castor cake per acre. The returns from this plat were closely followed by the yield on a plat receiving ashes of dung at the rate of 38 maunds per acre. Sun hemp used as a green manure gave almost as good results as the use of 38 maunds of cow manure alone. The results of the experiments with wheat were largely in favor of the use of 125 maunds of cow manure. Indigo, sun hemp, kurthi, and mung sown the second week of July and plowed under for green manure the second week of August, did not give very good results, indigo being the only one netting a small profit. Sugar cane was damaged by white ants and no results are reported.

Umballa potatoes were planted to compare the results from whole tubers and cuttings as seed. The whole tubers yielded at the rate of 9,200 lbs. per acre, and the cuttings at the rate of 8,200 lbs.

Twenty-nine varieties of paddy were grown for comparison and the largest yield of both grain and straw, being 2,700 and 10,440 lbs., respectively, was obtained from Sukarel, a Bombay variety.

Twenty-six varieties of hard and soft wheat, including Indian and Australian varieties, were under test and the results are shown in a table. A soft white wheat from the United Provinces of Agra and Oudh led in yield of both grain and straw, being 3,096 and 4,320 lbs., respectively.

Of 8 varieties of sugar cane Khari and Hullu Cabu led in yield. Thin canes gave the best results.

Six varieties of oats were sown the last week of October, and of these the local variety and Canadian Welcome were harvested the second week of March, and New Zealand, White Canadian, and Algerian the second week of April. The local variety was the most prolific, leading in yield with 4,800 lbs. of grain and 6,400 lbs. of straw per acre. Canadian Welcome gave a yield of 2,400 lbs. of grain and 4,800 lbs. of straw. The other varieties gave unprofitable yields of grain.

Three varieties of American sweet potatoes were compared with the local variety, and the yields obtained per acre were as follows: New Jersey 8,000, Mansimond 5,700, Virginia 4,800, and the local variety 6,400 lbs.

A number of forage and other crops were tested and brief notes are given on this work.

Annual report of the Burdwan Experimental Farm, 1902-3, D. N. MOOKERJI (*Dept. Land Records and Agr., Bengal, Ann. Rpt. Burdwan Expt. Farm 1902-3, pp. 10*).—A brief description of the farm and a record of the rainfall during the year are given, and the results of experiments are reported. Similar experiments have been previously noted (E. S. R., 15, p. 463).

[a] Legal maund of India about 82 lbs.

The results with different manures were again in favor of bone meal and saltpeter. Where the different fertilizers were applied in quantities furnishing 50 lbs. of nitrogen per acre, the net profit was not very high. Green manuring with jute and sun hemp (*Crotalaria juncea*) produced larger yields than the application of 50 maunds of cow manure. Paddy sown at the rate of 30 lbs. per acre yielded 3,030 lbs. of grain and 6,254 lbs. of straw; while a sowing at the rate of 60 lbs. per acre yielded 2,983 lbs. of grain and 6,129 lbs. of straw. Among 6 varieties of paddy from different sources Sukhavel and Kamode, both Bombay varieties, gave the most promising results.

The results with potatoes show that castor cake applied alone gave the largest yield. Rape cake and saltpeter gave a larger yield than rape cake alone. From the data obtained saltpeter is regarded as an unsuitable fertilizer for potatoes. The only profitable applications were farm-pitted cow manure, castor cake, and castor cake and saltpeter. Green manuring either with or without other fertilizers was also profitable. Whole tubers gave a better yield than cuttings. Five varieties varied in yield from 8,820 lbs. to 21,156 lbs. per acre. Patna stood first in yield and profit.

The Woburn field experiments, 1902, J. A. Voelcker (*Jour. Roy. Agr. Soc. England, 64 (1903), pp. 328–347, figs. 4*).—These experiments are in continuation of previously reported work (E. S. R., 15, p. 765).

The results with growing wheat and barley continuously under different annual fertilizer treatment are tabulated and discussed. The fertilizers used in this connection were ammonia salts, or equal quantities of sulphate of ammonia and muriate of ammonia containing 50 lbs. of ammonia; nitrate of soda furnishing as much nitrogen as 50 lbs. of ammonia; and mixed minerals consisting of 3.5 cwt. of superphosphate of lime, 200 lbs. of sulphate of potash, 100 lbs. of sulphate of soda, and 100 lbs. of sulphate of magnesia per acre. Rape cake was applied in quantities furnishing 50 or 100 lbs. of ammonia, and barnyard manure in quantities furnishing 200 lbs. of ammonia per acre.

In the tests with wheat this year nitrate of soda applied alone gave 25 bu. per acre, or 1.5 bu. more than the average, and where mixed minerals were given with it, 35.8 bu. per acre were obtained; but doubling the quantity of the nitrate in this combination gave a smaller yield. Ammonia salts gave much less satisfactory results than nitrate of soda, but the plat which had received lime at the rate of 2 tons per acre in 1897, yielded 8 bu. more than the plat which this season had received ammonia salts alone. The nitrate of soda plat also gave better results than ammonia salts and minerals, and ammonia salts doubled in quantity. Barnyard manure gave the best yield, 39.4 bu. per acre, being followed by the larger application of rape cake with 37.5 bu.

Hallett Pedigree barley was grown this season in these fertilizer tests. Ammonia salts without lime gave low yields, less than 1 bu. per acre being obtained when used alone. With the addition of lime applied in 1897, the yield was 29.6 bu.; while with mineral manures they gave a yield of 51.4 bu. per acre. The highest returns, 53.4 bu. per acre, were obtained from the plat receiving minerals annually and a double quantity of ammonia salts every other year, including 1902. The barnyard manure plat yielded 49.8 bu. and the heavily fertilized rape-cake plat, 48.3 bu. per acre.

In rotation experiments a fourth successive barley crop grown without manure yielded at the rate of from 16 to 32.1 bu. per acre. The rotation test in progress on Lansome Field resulted in the best yield of barley on the plats receiving decorticated cotton cake as a top dressing. The use of maize meal remained without effect. Mustard, rape, and tares were grown on this same field for green manuring. One-half of each plat was fertilized at the rate of 3 cwt. of superphosphate and 2 cwt. of kainit per acre.

Mustard made a much better growth than the other crops, and the results for 6 years show that the mustard has been a more effective green manure than the tares.

This season the mustard plants on the fertilized portions of the plats were practically all healthy, while those on the unfertilized portions were greatly affected by finger-and-toe disease. It is not known whether or not this result was due to the fertilizers applied. The first cutting of mustard in 1902 yielded 6,888 lbs. of green crop per acre, and the corresponding cutting of tares 8,463 lbs. These yields furnished 27.5 and 60.1 lbs. of nitrogen per acre, respectively.

Tests of 2 grass mixtures consisting of grasses and clovers together with certain deep-rooting plants, such as chicory, burnet, and kidney vetch, are described. The rotation consists of pasture 4 or 5 years and roots, cereals, and roots each 1 year, after which the land is again seeded to grass in a cereal crop. This year was a first season for the grass crop, and the yields were over 3 tons 7 cwt. for one mixture, and over 2 tons 18 cwt. for the other.

Experiments on the prevention of potato disease on Lansome Field in 1902 showed that where potatoes were sprayed July 24 with a mixture consisting of 20 lbs. of sulphate of copper, 20 lbs. of lime, and 100 gal. of water, there were never more than 2 cwt. of diseased tubers per acre as compared with 17 cwt. for the unsprayed crop. Spraying appeared to prolong the period of growth and to increase the starch assimilation. In connection with this experiment, manure from bullocks fed linseed cake and decorticated cotton cake was more effective than manure from bullocks fed beans, oats, and wheat.

Fresh lime at the rate of 2 tons per acre seemed more effective in reducing finger-and-toe disease in turnips than either gas lime, finely ground lime, or lime treated with carbolic acid applied at the same rate. Basic slag at the rate of 10 cwt. per acre was not as effective as the different forms of lime.

Cooperative field experiments, 1903 (*Jour. Dept. Agr. and Tech. Instr. Ireland, 4 (1904), No. 3, pp. 469–510*).—Similar experiments were made in 1902 (E. S. R., 15, p. 664). In a variety test Archer Chevalier barley, as in previous years, gave a better average yield than either Goldthorpe or Standwell, but in quality it was inferior to these varieties. Goldthorpe and Standwell mature better than Archer Chevalier in unfavorable ripening weather, but are subject to loss through the dropping off of the heads.

The results of fertilizer experiments with Archer Chevalier showed but a nominal profit, and indicated that in general each farm needs its individual fertilizer treatment. For soils in a low state of fertility the application used, consisting of 1 cwt. of sulphate of ammonia, 3 cwt. of superphosphate, and 2 cwt. of kainit, was productive of good results.

In a second series of tests Archer Chevalier gave a better yield and a higher return than Garton Brewers' Favorite, Garton Invincible, Hallett Pedigree, and Scotch Chevalier. In previous years Hallett Pedigree and Scotch Chevalier were much superior in quality in certain counties. The Garton varieties stood low in money value per acre, but in quality and manner of ripening they ranked above the Chevalier varieties.

A fertilizer test was made on the same farms with 1 cwt. of sulphate of ammonia and 3 cwt. each of superphosphate and kainit per acre, applied in different combinations. Sulphate of ammonia given alone invariably retarded the ripening and showed tendency of producing a late second growth, especially during a wet season. Superphosphate and sulphate of ammonia given together produced a very profitable average increase. The addition of kainit to the mixture had but little effect. The use of superphosphate and kainit had a very marked effect upon the quality of the grain.

Fertilizer experiments on meadows are reported and, based on the results obtained, a general application of 1 cwt. of nitrate of soda, 2 cwt. of superphosphate, and 2 cwt. of kainit per acre for meadow lands is recommended.

The most profitable application for potatoes consisted of 15 tons of barnyard manure, 1 cwt. of sulphate of ammonia, 4 cwt. of superphosphate, and 1 cwt. of muriate of potash. Without the muriate of potash the profit was reduced about £1 per acre, and the omission of superphosphate caused a further reduction of 34 shillings. In a variety test, Up-to-Date and Beauty of Bute led in yield and produced 5 tons per acre more than Reliance, which ranked last among the 10 varieties grown.

Fodder beets, treated the same as the year before, produced good yields with the use of 15 tons of barnyard manure per acre, but the addition of a complete application of commercial fertilizers to the manure again proved profitable. Four cwt. of salt substituted for 2 cwt. of kainit in this application increased the yield by 24 cwt.

Kainit used alone as a fertilizer for oats has given poor results for 3 successive years. The best result was obtained from the use of 1 cwt. of sulphate of ammonia, 3 cwt. of superphosphate, and 3 cwt. of kainit. The variety test resulted in favor of Goldfinder, Canadian Banner, and Waverley, the 3 varieties being practically equal in their yields.

A complete application of commercial fertilizers for turnips proved better than an incomplete mixture. The results with barnyard manure were similar to those of the previous year.

Report of investigations at the Highmore Station for 1903, W. A. WHEELER (*South Dakota Sta. Bul. 84, pp. 3-8*).—An account of the growth at the station of a number of varieties of grasses, alfalfa, millets, sorghums, corn, rape, and kale. Of 3 varieties of alfalfa the heaviest yield, 3,642 lbs. of hay per acre, was afforded by Samarkand sown in 1900. Siberian millet gave the best yield of 5 varieties tested, namely, 5,410 lbs. per acre. Of the sorghums, Amber Cane and Wisconsin Early Amber yielded over 5 tons each of cured cane per acre. Branching Doura yielded 5,370 lbs.; Jerusalem corn, 2,197 lbs.; Earliest Kafir corn, 4,430 lbs.; milo maize, 5,650 lbs.; and teosinte, 4,340 lbs. per acre.

Early Huron Dent corn yielded at the rate of 18½ bu. per acre; Yellow Dent corn, 21 bu. per acre; Squaw corn, 23½ bu. per acre; Queen of the North, King of the Earliest, and Reid Yellow Dent ripened from one-fourth to one-third of a crop; Iowa Gold Mine, Early Giant White, Wisconsin White Dent, and Riley Favorite corn did not ripen. Superior fodder corn yielded at the rate of about 23⅓ tons of green fodder, or 7⅜ tons of cured fodder per acre. Rape yielded from 3¼ to 4⅝ ton, per acre, and kale at the rate of 6½ tons of green fodder per acre.

References to recent work on plant breeding, C. FRUWIRTH (*Jour. Landw., 52 (1904), No. 3, pp. 269-290*).—References are given to 31 recent articles on plant breeding in connection with different crops. Each reference is accompanied by a brief abstract of the particular article. A previous list of similar references is noted in E. S. R., 15, p. 770.

Reports on the third and fourth years' breeding experiments with root crops at Danish plant experiment stations, 1902-3, L. HELWEG (*Tidsskr. Landbr. Planteavl, 11 (1904), pp. 1-20, 324-364*).—The reports contain the usual accounts of the plant-breeding experiments with Elvetham and Eckendorfer mangolds, and with Yellow Tankard, Funen Bortfelder, Bulloch, and New Bronze turnips during the years 1902 and 1903. A paper on Breeding Centers for Fodder Beets, by the author, and the discussion of the same is also given.

The yields of roots and of dry matter per töndeland were determined in the crops produced from the different varieties, and these were scored for uniformity of shape in the roots grown therefrom. The seed produced from the various strains was separated into three classes, according to its quality. The improvement in the quality of the seed of root crops placed on the Danish market is illustrated by the fact that in the spring of 1900, at the beginning of these experiments, only 35,770 lbs. of seed of first-class strains were on the market, against about 350,000 lbs. in the spring of 1904.—F. W. WOLL.

Summary of press bulletins, J. FIELDS (*Oklahoma Sta. Rpt. 1904, pp. 24-40*).—Results obtained at the station from year to year in different lines of work are briefly noted and summarized. The average results for 4 years show that wheat sown about September 15 and October 15 yielded 31.82 and 31.06 bu. per acre, respectively, while wheat sown about November 15 averaged for 3 years only 20.49 bu. per acre. The average results for 4 years on land plowed at different dates are in favor of early plowing, the yields of wheat being 30, 27.7, and 25.65 bu. per acre from July, August, and September plowing, respectively.

On a plat of 1 acre wheat has been grown continuously since 1893. One-half of the plat received 15 tons of barnyard manure per acre in the fall of 1898 and another application at the rate of 11 tons per acre in the fall of 1899. Since then no manure or fertilizer has been applied. The yield for the year 1902-3 was 27.6 bu. for the manured portion and 20.3 bu. for the unmanured portion of the plat, and the average per acre for 5 years, 30.02 and 18.74 bu., respectively.

Since 1892 over 250 varieties of wheat have been tested at the station, and out of this list 25 were grown during the past season. Red Russian, Missouri Blue Stem, Pickaway, Early Red Clawson, German Emperor, New Red Wonder, Big English, Sibley New Golden, Crimean, Paris, and Fultzo-Mediterranean yielded from 36 to 39.5 bu. per acre; Fulcaster, Early Ripe, Turkey, Oregon Red, and Gypsy Amber, from 33 to 36 bu. per acre, and Fultz, Eversaw, and Weissenburg, from 30 to 33 bu. per acre.

Experiments in pasturing wheat, begun in the fall of 1902, have so far shown that light winter pasturing reduces the yield but little, while late spring pasturing causes a marked reduction in the yield of both grain and straw. A plat not pastured yielded 23.2 bu. of grain and 1.49 tons of straw per acre, while a plat pastured lightly during the winter and late in the spring yielded only 10.7 bu. of grain and 0.83 ton of straw per acre.

The average yields of Kafir corn for 4 years amounted to 4,422 lbs. of stover and 1,506 lbs. of grain, and of Indian corn 1,951 lbs. of stover and 622 lbs. of grain per acre.

Notes are given on seeding wheat, growing oats, selecting seed corn as well as Kafir corn and cotton seed, and the growing of rape and Bermuda grass.

Notes on agriculture in the United States, F. BRETTREICH (*Vrtljschr. Bayer. Landw. Rat., 9 (1904), No. 2, app., pp. 125*).—This contains statistical matter compiled from various sources, and the author's observations on the different lines of agriculture in the United States.

Grazing problems in the Western States, E. V. WILCOX (*Out West, 19 (1903), No. 4, pp. 444-449*).—Attention is called to the intimate relationship between the development of the range stock business and the system of management and the condition of the range. Great deterioration in range conditions has been noted in a number of localities, and a system of leasing the public domain is recommended as a means of preventing the wanton destruction of the grazing lands.

Alfalfa in New York, J. L. STONE (*New York Cornell Sta. Bul. 221, pp. 14, figs. 2*).—This bulletin discusses the damage to alfalfa fields in New York resulting from the severe winter of 1903-4, and presents suggestions regarding the culture of the crop.

Alfalfa or lucern, J. H. GRISDALE, F. T. SHUTT, and J. FLETCHER (*Canada Cent. Expt. Farm Bul. 46, pp. 19, pls. 2, figs. 4*).—This bulletin discusses the culture and uses of alfalfa, points out its value as a fodder and a fertilizer, and treats the subject from a botanical and historical standpoint. The results obtained at the Canada Experimental Farms with this crop are reviewed, and its composition as a fodder and fertilizer is compared with that of other forage crops.

Manurial experiments with barley (*Jour. Bd. Agr. [London], 11 (1904), No. 4, pp. 211-214*).—These experiments were made at the Midland Dairy Institute in 1903.

Nitrate of soda was applied at the rate of either 1 or 2 cwts. per acre, and superphosphate and kainit at the rate of either 2 or 4 cwts. An application of 1 cwt. of nitrate of soda and 2 cwt. each of superphosphate and kainit per acre served as a standard for comparison. Doubling the quantity of nitrogen increased the average yield by 3 cwt. 47.5 lbs. per acre, and doubling the quantity of kainit gave an increase of only 85.5 lbs. The larger dressings of superphosphates diminished the yield about 25.5 lbs. per acre. The largest crops were obtained on the plats receiving 2 cwt. of nitrate of soda per acre. No difference was observed in the quality of the barley from the various plats.

A fertilizer experiment with barley carried out by the Yorkshire College indicated that a complete application of commercial fertilizers gives the best results, the best yield, the lowest percentage of nitrogen, the highest proportion of potash, the highest proportion of extract, and the highest diastatic capacity being all in its favor.

The influence of early and late spring plowing upon corn production, M. QUIROGA (*Ohio State Univ. Bul., 8. ser., No. 28 (Agr. Ser. No. 1), pp. 23, charts 3*).—Land was plowed for corn on April 7 and 10 and on June 3. The corn was planted June 4.

The effect of early and late plowing on soil moisture, available nitrogen, and soil temperature was studied. The early-plowed land yielded on an average 6.6 bu. more per acre, showed a greater moisture-holding capacity, especially in the surface foot, and contained much more available nitrogen and a greater amount of water than the late-plowed land. The yield showed a close relation to the amount of moisture and of available nitrogen in the soil during the season. On this particular soil a moisture content below 12 per cent caused the leaves of many plants to curl early in the day, turned the plant yellow, and interfered more or less with its growth.

Nitrification took place with a gradually decreasing intensity at 1, 2, and 3 ft. in depth. The surface foot of the early-plowed land contained twice the seasonal average amount of available nitrogen found on the late-plowed land. Furthermore, the available nitrogen in the surface foot of the early-plowed field was 4 times the quantity in either the second or third foot of the early or late plowed plats.

The late-plowed soil showed the higher mean soil temperature during the entire season and the low mean soil temperature of the early-plowed land was accompanied throughout the season by a greater amount of moisture and available nitrogen. The author states that a high temperature is not always followed by a high rate of nitrification, and he believes, therefore, that the process of nitrification is dependent upon the rate relation between the water content and the temperature of the soil, provided other factors are favorable.

Corn culture at Ivoloina, G. DUCHÊNE (*Agr. Prat. Pays Chauds, 3 (1904), No. 17, pp. 612–616*).—Corn was planted at the experiment station at Ivoloina, Madagascar, between rows of castilloa. The crop planted March 21 matured in 110 days and yielded at the rate of 3,276 kg. of shelled corn per hectare. The castilloa plants grew vigorously and developed symmetrically so long as they were protected by the corn, but when this was removed their development on the side toward the prevailing winds was materially reduced.

The commercial cotton crops of 1900–1901, 1901–2, and 1902–3, J. L. WATKINS (*U. S. Dept. Agr., Bureau of Statistics Bul. 28, pp. 83*).—Statistics with reference to the commercial cotton crops of these years are given, and the commercial crops of 1900–1901 and 1901–2 in each of the cotton-growing States are compared. The consumption of cotton in the United States and the world and the total value of cotton crops in this country are discussed. The shipments made in the different States in 1902–3 are recorded for each railroad station. The cost of picking cotton in the different years is given, and the exports and imports of cotton for the United States during the period are shown in tables. The cotton industry of Brazil is briefly described.

Quantity of cotton ginned in the United States (*U. S. Dept. Com. and Labor, Bureau of the Census Bul. 10, pp. 56, maps 14*).—This bulletin is a report of the cotton crop grown in 1903, accompanied by comparative statistics of the crops for the years 1899 to 1902, inclusive. The statistics presented cover the quantity of cotton ginned from the growth of each year as distinguished from the quantity marketed from September 1 to August 31. In addition the bulletin gives the quantity of cotton reclaimed by thrashing cotton bolls, the vitality of which was destroyed; an estimate of the quantity destroyed by the boll weevil and of its influence on the cotton production of the infested district of Texas; and the distribution by States of the quantity of linter cotton saved by the cotton-seed oil mills by reginning the seed of the crop of 1903.

Cowpeas and soy beans, D. O. NOURSE (*Virginia Sta. Bul. 149, pp. 93–99*).—Brief notes are given on the growth at the station of 20 varieties of soy beans and 10 varieties of cowpeas. The varieties were planted May 18 and 19, and a description is given of their condition on September 11 and 12. Promising results were obtained from varieties introduced by this Department and designated as Department of Agriculture Nos. 8422, 8423, 8424, 8497, 9409, 9415, and 9416, the yields of green product ranging from 11,200 to 18,200 lbs. per acre. Among the cowpeas, Southern, Wonderful, Iron, and Clay, yielding 19,950, 16,400, 15,050, and 14,000 lbs. of green substance per acre, respectively, were the most productive varieties.

Flax experiments, 1903 (*Jour. Dept. Agr. and Tech. Instr. Ireland, 4 (1904), No. 4, pp. 616–638*).—With one exception in the variety tests, these experiments were carried on along the same lines as those of 1902, which have already been described (E. S. R., 15, p. 667).

In cooperative fertilizer experiments the flax yellowed to some extent on all plats excepting on those which had received potassic fertilizers. The plats fertilized with muriate of potash and kainit had the best appearance. The general results with 6 cwt. of kainit per acre show an increase in the yield of straw and of scutched flax. Muriate of potash at the rate of 1.25 cwt. per acre apparently increased the yield of straw and flax, produced a higher percentage of fiber of a slightly better quality, and gave a profit of 17s. 1d. per acre as compared with the unmanured plats.

Plats receiving a mixture of kainit and superphosphate at the rate of 3 cwt. each per acre gave an increase of retted straw and of scutched flax and a decrease in the proportion of scutched flax to straw as compared with the check plat, but the increase in the yield did not defray the cost of the fertilizers. With the addition of 0.5 cwt. of sulphate of ammonia, this mixture increased the yields of straw and flax and the proportion of flax to straw, improved the quality of the flax, and produced a gain in financial results. Five cwt. of rape meal per acre produced good effects, but was unprofitable. Basic slag at the same rate was also applied at a loss. From the results obtained for 3 years it is concluded that the use of a potassic fertilizer, such as muriate of potash or kainit, may be expected to give profitable returns, and that of the 2 fertilizers the muriate is preferable.

In the variety tests of this year English-saved seed was substituted for Riga Pernau Crown seed. Two strains of Dutch seed, Belfast Brand and Riga Child, gave the best results, the Belfast Brand giving slightly better returns than the Riga Child.

Scutching trials with the Irish and the Belgian Courtrai system are again reported, and it is believed "that with practice on a modified Belgian mill Irish workmen would show better results from the use of such a mill than are obtained from an Irish mill." The results of scutching Belgian retted straw by a Belgian mill and by Irish mills gave about the same results as in the previous year, but the difference between the net returns from the straw scutched on the Belgian mill at Courtrai, as compared with those from the Irish mills, was not so great.

Rippled straw yielded only slightly less flax of a slightly inferior quality than nonrippled straw, but the yield of seed was so small that it only just compensated for the decrease in yield and quality of flax and for the extra labor.

Continental methods of retting and scutching were tried on the Continent with Irish flax, and the system of treatment practiced in Lokeren, Flanders, resulted in the highest yield of scutched flax. The quality was better than that of flax scutched at Courtrai after retting in the Lys. Flax steeped once in the Lys at Courtrai gave better results than flax steeped twice. A report by a committee of inspection on the culture and handling of flax in Belgium and Holland is presented.

Perennial and Italian rye grass, D. FINLAYSON and J. S. REMINGTON (*Aynsome Agr. Sta., Grange-over-Sands, Cent. Seed-Testing Lab. Farmers' Bul. 6, pp. 8, pl. 1*).—Notes are given on these grasses and the purity and germination of the samples of seed tested at the Central Seed Testing Laboratory are recorded. A number of impurities common in the seed of rye grasses are illustrated. The average purity of 56 samples of Italian rye grass seed was 93.4 per cent, the average germination, 88.5 per cent; and the average purity of 59 samples of perennial rye grass, 96.5 per cent, and the average germination, 98 per cent.

Plant food removed in the pruning of hop plants, HORECKY (*Deut. Landw. Presse, 31 (1904), No. 57, pp. 500, 501*).—Hop plants were pruned April 20, and analyses were made of roots taken up at this time, and of the new shoots removed in pruning. The method of analyses is described and the results obtained, as given below, are shown in tables:

Analyses of the roots and young shoots of Saaz, Auscha, and native hop plants.

	Roots.			Shoots.		
	Saaz.	Auscha.	Native.	Saaz.	Auscha.	Native.
	P. ct.	*P. ct.*	*P. ct.*	*P. ct.*	*P. ct.*	*P. ct.*
Dry matter	38.480	29.550	30.560	17.760	19.510	16.460
Potash	.996	.978	.628	.973	.919	.803

Report on experiments on the comparative merits of varieties of oats in 1900, R. P. WRIGHT, A. N. M'ALPINE, and J. W. PATERSON (*West of Scotland Agr. Col. Rpt. 1900, pp. 167–246, charts 6*).—The results of this work for 1899 have been previously reported (E. S. R., 13, p. 131). This season Banner, Waverly, Tartar King, and Newmarket were the most productive, yielding from 2,101 to 2,141 lbs. of grain per acre. Sandy and Tam Finlay led in the yield of straw. On rich soils the varieties most productive in grain were most profitable, while on poor soils the varieties most productive in straw gave the best results. Among the best grain-producing varieties Banner and Waverly are considered the most highly productive and the most generally valuable. In addition to the varieties mentioned Potato, Hamilton, Longhoughton, and Golden Giant were grown, and each one of the varieties is described and its previous record discussed at some length.

Report on the botanical aspects of the oat variety investigations as shown by the experiments made in frames set in the fields, A. N. M'ALPINE (*West of Scotland Agr. Col. Rpt. 1900, pp. 247–284*).—These investigations were made with the varieties of oats entering into the experiments referred to in the above abstract. The tests were carried out on the same fields and under similar conditions, in frames 1 sq. ft. in size, and sown the same as the plats at the rate of 2½ million seeds per acre. The principal data obtained are given in the following tables:

Average results obtained on the different farms.

Farms.	Average germination of seed.	Sheets per 100 plants.	Straws per 100 plants.	Barren shoots.	Straws per 100 seeds.	Straws per acre.	Length of straw.	Weight per straw.	Number of spikelets per ear.

Potato	86	151	112	27	96	2.400	47	1.21	61
Sandy	83	205	140	31	116	2.900	51	1.13	67
Hamilton	82	180	127	30	104	2.600	49	1.17	62
Tartar King	76	141	104	20	80	2.000	45	1.40	40
Tam Finlay	75	243	153	37	115	2.875	49	1.15	50
Waverley	75	146	116	20	83	2.075	47	1.13	29
Longhoughton	73	151	110	28	80	2.000	45	1.16	49
Newmarket	73	162	113	30	83	2.075	45	1.14	24

The observations on the germinating power of the seed show that Potato, Sandy, and Hamilton outranked all other varieties. Tillering power on the different farms was not an indication of high yields. Tam Finlay and Sandy tillered most and produced the largest number of straws and the largest number of barren shoots. The conclusion is drawn from the study of crop density that the best thickness of oats lies between 2 and 2.6 million straws per acre. Sandy, Hamilton, and Potato produced the largest number of spikelets per head.

Report of the results of the analyses of oats (grain and straw) grown in the oat variety experiment, J. W. Paterson (*West of Scotland Agr. Col. Rpt. 1900, pp. 285–288*).—The analyses here reported were made in connection with the experiments described in the foregoing abstract. The samples of both grain and straw were dried at 100° C. The grain of only 4 varieties was analyzed, while the composition of the straw of all varieties was determined.

Composition of the grain.

Variety.	Crude protein.	Oil, etc.	Carbohydrates.	Woody fiber.	Ash.	Moisture in fresh sample.
	Per cent.	*Per cent.*	*Per cent.*	*Per cent.*	*Per cent.*	*Per cent.*
Potato	11.91	8.26	65.18	11.91	2.74	15.97
Banner	12.42	6.17	65.66	12.56	3.19	16.37
Waverley	11.60	5.93	66.80	12.56	3.11	16.33
Newmarket	12.00	5.95	68.49	10.57	2.99	16.42

The average composition of the straw of the 10 varieties taken from each farm, as in the grain samples, was as follows: Crude protein 2.34, albumen 2.03, amids 0.30, oil 2.03, carbohydrates 42.02, woody fiber 46.85, ash 6.76, and moisture in fresh

sample 10.74. Samples of the straw from two of the farms were analyzed separately in addition, to show that soil and climate had a greater influence on the composition of the straw than on the composition of the grain.

Some investigations of transmission and variability in oats, with special reference to the possibility of isolating types high in fat adapted to the manufacture of shelled oats, A. V. KRARUP (*Copenhagen: Aug. Bang, 1903, pp. 70*).—The variety of oats with which the author conducted his extensive investigations was Beseler. This variety was chosen on account of its relatively high content of fat and nitrogen, clean kernels, and thin hulls, qualities desirable for the manufacture of shelled oats. The crops grown during 4 successive years (1899–1903) were studied to determine correlation in characters and the fixedness of the characters in the strains grown.

The oats used in the first year's work were found to contain different types of greatly differing characters. Five isolated types were grown for 4 years, 2 of which were high in fat, 2 medium high (1 with high kernel weight), and 1 low in fat. Kernels taken from the outer and inner portions of the panicle were compared. A correlation was found in the data for fat content and kernel weight, increasing kernel weight being in general associated with decreasing fat content, and vice versa. While there is no absolute uniformity in this relation, it is sufficiently regular to furnish a reliable method for determining the relative fat content of different crops of the same variety from the weights of outer grains.

An increase in fat content and a decrease in kernel weight, as a rule, accompanied an increase in the number of panicles, and a high kernel weight appeared to be associated with a low nitrogen content and a high percentage of hulls. The quality of the crop does not appear to be influenced by the different properties of plants grown from outer and inner kernels of the same parent plant. In general, the selection of varying individuals within the same strain or family did not influence to any appreciable extent the qualitative properties of the offspring, showing that the types isolated from the original seed oats in 1899 were quite fixed.

A bibliography of 17 references is given at the close of the report.—F. W. WOLL.

Transmission of characters in potatoes, C. VON SEELHORST and W. FRECKMANN (*Jour. Landw., 52 (1904), No. 1–2, pp. 151–162, dgms. 5*).—Experiments have been in progress for several years to demonstrate the possibility of increasing the yielding capacity of varieties by selecting the seed tubers from large prolific plants. For this purpose large and small tubers of 3 varieties selected from both large and small plants were used for seed, and the results obtained are here tabulated and presented graphically. The mother plants were classified with reference to size according to their weight. The relation of the size of the mother plants to the specific gravity of the progeny, and of the specific gravity of the one to the specific gravity of the other, is also shown.

The authors conclude that the experiments indicate that seed selected from strong and prolific plants increases productiveness. The form of the mother plants also seems to be a character capable of transmission, and it is recommended that in selection the form also be taken into consideration.

Potato production (*Quart. Rpt. Kansas State Bd. Agr., 23 (1904), No. 91, pp. 205, figs. 9*).—This publication is a compilation of articles on the culture and uses of the potato and the sweet potato. The experience of Kansas potato growers, with estimates of the cost of production per acre, are given by counties. The total production of potatoes in different counties for the years 1899 to 1903, inclusive, is shown in a table. The culture of the sweet potato in Kansas is also discussed.

New white potato, T. HAYNES (*U. S. Dept. Com. and Labor, Mo. Consular Rpts., 1904, No. 286, pp. 78, 79*).—A description is given of this plant, which is *Solanum commersonii*, and its probable value is pointed out. An instance is cited where, in

1903, 98 per cent of the tubercles of this new potato were in good condition, while of the Early Rose potato grown under similar conditions, but having been affected by plant diseases, only 15 per cent were good. The yield of this new potato was also much greater than that of the Early Rose and the American Marvel.

Sorghum as a sirup plant, J. S. NEWMAN ET AL. (*South Carolina Sta. Bul. 88, pp. 31*).—The study of sorghum as a sugar and sirup producing plant is briefly noted, and the results obtained at the station from 1900 to 1903, including chemical data, are reported.

In 1900, 13 pedigreed varieties were grown; in 1901, 12; in 1902, 6, and in 1903, 7. Prior to 1903 the results were based on the analysis of the cane and the practical working of the same for the production of sirup, but during the last season only chemical analyses were made. The yield of sirup per acre in 1900 ranged from 30.3 to 155.6 gal. per acre, the corresponding yields of stripped cane being 15,756 and 6,201 lbs. per acre, respectively. These yields of cane also represent the extremes. In 1901 and 1902 the sirup production ranged from 53.6 to 94.7 gal. and from 24.9 to 72.8 gal., respectively. The results obtained in 1903 are given in the table below:

Results with varieties of sorghum in 1903.

Name of variety.	Stripped cane per plat.	Juice per plat.	Stripped cane per acre.	Juice per acre.	Juice in cane.	Cane sugar in juice.	Sugar per acre.
	Pounds.	*Pounds.*	*Pounds.*	*Pounds.*	*P. ct.*	*P. ct.*	*Pounds.*
Amber, western grown	250.0	78.8	6,250.0	1,970.0	31.52	13.65	268.90
Amber, home grown	417.5	118.9	10,437.5	2,972.5	28.47	16.12	479.36
Early Orange	425.0	154.4	10,625.0	3,860.0	36.32	15.49	566.56
Kansas Orange	400.0	112.5	10,000.0	2,812.5	28.12	15.77	443.52
Folger	330.0	89.5	8,250.0	2,237.5	27.12	13.02	291.32
Coleman	395.0	117.8	9,875.0	2,945.0	29.82	13.43	395.51
Collier	385.0	109.5	9,625.0	2,737.5	28.44	15.97	437.17

In one test plants were thinned to 4, 3, 2, and 1 stalks per foot of row and the yields of sugar obtained per acre were 78.14, 87.36, 115.45, and 116.55 lbs., respectively. The best yields of cane and sugar per acre were obtained from a planting made April 21, as compared with plantings made May 6 and 22 and June 10; but the percentage of sugar was highest in the cane planted latest. The results of a fertilizer test lead the authors to infer that 250 lbs. of cotton-seed meal per acre would be as effective in producing cane and sirup as 200 lbs. of cotton-seed meal, 300 lbs. of acid phosphate, and 80 lbs. of kainit per acre. These experiments have been in progress only one season.

The total solids, sucrose, and purity coefficient were determined in the samples for the different experiments and are recorded. In the variety test for 1903 the average of all the samples gave 20.04 per cent of total solids, 14.78 per cent of sucrose, and 73.8 per cent of purity. The average results of 6 fiber determinations gave 10.15 per cent of fiber and 89.85 per cent of juice. Data obtained in connection with work on sorghum in 1898, 1899, 1900, and 1901 are also recorded in tables and noted.

Experiments with sugar beets in 1903, C. D. SMITH (*Michigan Sta. Bul. 215, pp. 19*).—In studying the variation of sugar content in beets the author found that in one instance the difference in sugar content of adjacent beets grown from the same seed and under identical conditions amounted to over 3 per cent, while a difference of over 2 per cent was frequently shown.

Two methods of sampling were compared. In the first, 1 beet was selected every 5 paces in each row of the plat, making a composite sample of 45 beets, and in the second, 10 beets were taken from the low and high areas of the plat for the purpose of representing each soil type. The first sample showed 14 per cent of sugar with a purity of 83.9, and the second, 13.2 per cent of sugar with a purity of 80. The loss

in weight of beets sent to the station was sufficient to make a difference of from 3 to $4\frac{1}{2}$ per cent in the sugar content. A beet stripped of its leaves but not topped, sent by mail well wrapped, and in transit 72 hours lost 13.79 per cent in weight, while a topped sample sent under the same conditions lost 12.90 per cent.

An experiment in lifting beets, to prevent a second growth, by breaking the tap roots and tearing the lateral roots, seemed in the particular instance to have prevented a change in the composition of the beets.

The weight of the roots, crowns, and leaves in 2 lots of clean, untopped beets was determined and the results showed that the leaves and crowns constituted from 40 to 44 per cent of the weight of the topped beets. The quantities of leaves and crowns in each test were about equal in weight.

A test of 16 varieties was conducted in 3 localities on different types of soil. The variation in sugar content in the same variety grown under different conditions was quite marked, and the results did not show that any one variety was superior on all 3 types of soil.

The studies on the exhaustion of the soil by beets was continued (E. S. R., 15, p. 35). Oats, beets, and corn were grown on plats of light sandy loam soil. One of the plats had produced beets 3 years in succession, while the others had been under different crop rotations. The yield of all these crops on the soil having been in beets for 3 successive years was much smaller than the yields on the 2 plats under rotation, and this is regarded as showing conclusively how continued beet culture would injure a light sandy loam soil. In summing up the results of a series of distance experiments the author states that a row narrower than 22 in. is advisable only on the very richest soils, and that a greater distance up to 28 in. between the rows is more profitable on soils of average fertility.

The fertilizer tests reported show that complete commercial fertilizer applications are profitable. The substances used were nitrate of soda and sulphate of potash given at the rate of 100 and 200 lbs. per acre, and dissolved South Carolina rock, at the rate of 200 and 400 lbs. per acre. The 3 plant-food elements were needed on all plats in the test except on one, which yielded nearly 15 tons per acre without the use of fertilizers. The results of work in previous years, showing that on the college farm reasonable quantities of nitrogen, phosphoric acid, and potash in beet culture may be applied with profit, are summarized.

An experiment was conducted in cooperation with this Department on the prevention of leaf blight by spraying with Bordeaux mixture or by manuring with nitrate of soda or common salt. The results did not warrant definite conclusions, but spraying apparently reduced leaf blight. Nitrate of soda gave a dark color to the plants. Common salt produced vigorous plants, but yellow in color, and did not show any effect on leaf blight.

Phosphate and potash fertilizers for beets, D. Kochenovski (*Zhur. Opuitn. Agron., 5 (1904), No. 3, pp. 326–327*).—The results here reported were obtained in the chemical laboratory of the Smyela Estate, owned by the Counts Bobrinski.

A series of 70 analyses of various beet soils showed that the soil yielding beets of the highest quality contained a smaller amount of nitrogen in relation to potash and phosphoric acid than the soils producing beets of inferior quality. From these results it appears that fertilizing with phosphoric acid and potash would improve the quality of the beets. On further investigation the author found that the beets poorest in quality for manufacturing purposes contained relatively the greatest amount of nitrogen. The contents of phosphoric acid stood in inverse ratio to the total weight of the root, and the consumption of potash was approximately proportional to the yield.

It is concluded that in order to obtain a large yield of good beets the soil must receive a definite amount of phosphoric acid and a large quantity of potash. It is stated that on soils containing less than 0.02 per cent of available phosphoric acid the use of phosphatic fertilizers is advantageous. The objection to the use of different

forms of potash is discussed, and the author proposes the use of a mixture of sugar-house refuse and kainit, in the expectation that under the influence of rain and air this mixture will form gypsum and potassium carbonate.—P. FIREMAN.

Experiments with sweet potatoes at Barbados, R. R. HALL and J. R. BOVELL (*West Indian Bul., 5 (1904), No. 1, pp. 41–52*).—The yield of tubers and vines and the analyses of both with reference to food and fertilizer constituents are tabulated for 28 varieties of sweet potatoes grown in a variety test. The heaviest yielding varieties were White Gilkes 4.97 tons per acre, Moffard 5.01 tons, Hurley 4.59 tons, Minuet 4.42 tons, and Vincelonian 3.49 tons per acre. The food units in pounds per acre are calculated for some of the varieties. Descriptions in brief notes are given of the 28 varieties tested.

Variety tests with vetch (Vicia sativa) and field peas (Pisum arvense) (*Deut. Landw. Presse, 31 (1904), No. 58, pp. 510, 511*).—Twelve varieties of vetch gave an average yield of 21,800 kg. of green forage and 5,028 kg. of hay per hectare; and 6 varieties of field peas, 25,830 kg. of green forage and 4,480 kg. of hay. With the exception of the Swedish variety, the varieties of field peas were about equal in hay production to the lowest ranking varieties of vetch. The field pea varieties varied 28 per cent in the production of air-dry substance, and the vetch varieties 33 per cent.

The yield of wheat at different latitudes, N. PASSERINI (*Atti R. Accad. Econ. Agr. Georg. Firenze, 5. ser., 1 (1904), No. 1, pp. 126–134*).—The average yield of wheat from different countries is considered, and it is pointed out that the countries of Europe may be divided into 3 groups, according to the average yield. The first or leading group consists of Denmark, Great Britain, Norway, and Sweden; the second of Germany, Holland, France, Belgium, Hungary, Roumania, and Austria, and the third of Italy, Servia, and Spain. The author concludes that the yield of cereals decreases with the latitude.

Wheat production and farm life in Argentina, F. W. BICKNELL (*U. S. Dept. Agr., Bureau of Statistics Bul. 27, pp. 100, pls. 10*).—This bulletin discusses at some length and with considerable detail the wheat industry of Argentina and the farm conditions under which it exists. The different subjects treated are the tenure of agricultural lands, the living conditions on average farms, the present and prospective wheat area of the country, the land and its treatment, and in general the culture and marketing of the crop. Statistics concerning the total area of wheat farms, the average size of farms, the cultivated and uncultivated but arable areas of the country, the price of farm lands, immigration and emigration, the yield of wheat, the cost of production and transportation, and the exportation of wheat and flour are also given.

The area of the wheat crop for 1903–4 is estimated at 10,230,311 acres, or from 15 to 20 per cent of the possible wheat area of the country. Only about one-third of the number of wheat farmers of Argentina till their own lands, the rest being renters, while in the United States only about one-third of the farmers are renters. In 1903 the available public lands amounted to 237,768,303 acres. The net immigration for the same year was 35,359.

The varieties of wheat grown are mainly soft or bread wheats, only a comparatively small quantity of durum wheat being produced. The more important varieties have been introduced from Italy, Russia, Hungary, and France. The cost of producing an acre of wheat is variously estimated at \$4.93, \$7.03, and \$7.40. The average yields per acre for 10 years, ending with 1901, in different sections of the country vary from 10.63 bu. to 38.84 bu. During the years 1892–1901 the total production of the country ranged from 31,593,571 bu. in 1897 to 99,075,349 bu. in 1900, while the average price per bushel for the same period varied from \$0.4793 in 1894 to \$0.8562 in 1897. The exportation of wheat reached its height in 1903, when, it is estimated, 75,000,000 bu. were shipped from the country. In addition, 809,628 bbls. of flour were exported.

Variety tests of wheat, G. C. WATSON and A. K. RISSER (*Pennsylvania Sta. Bul. 67, pp. 8*).—The experiments are described in general and the work of the season is noted. For the crop of 1903 the land was plowed about 8 in. deep August 20, 1902, top-dressed with 8 tons of barnyard manure per acre, harrowed several times, and rolled before seeding. Twenty varieties were sown September 8, at the rate of 8 pk. per acre, and the ground was given an application of 180 lbs. per acre of commercial rock phosphate.

The plats were harvested July 11. The average yield obtained per acre was 32.19 bu. The 13 smooth varieties averaged 32.09 bu., and the 7 bearded varieties, 32.33 bu. The leading varieties were Forty-Fold or Gold Coin, Royal Red Clawson, Dietz Longberry Red, Fulcaster, and Fultz, yielding 35.37, 34.98, 34.86, 34.21, and 34.05 bu. per acre, respectively. American Bronze ranked last, with a yield per acre of 26.90 bu. The bearded varieties weighed 1.67 lbs. more per measured bushel than the smooth sorts.

In addition to the yields for the season, the average yield for the entire period of the experiment is also reported. Of the varieties under test for 14 years, Fulcaster and Reliable have given the best general results. Fulcaster leads in yield of grain and straw, and in the weight per measured bushel. Among the varieties grown for 8 years, Royal Red Clawson has given promising results, and of those grown 3 years, Turkish Amber has been most satisfactory.

The results with early and late seeding have varied in different years, and the conclusion is drawn that the season largely governs the time of sowing.

Cooperative cereal investigations at Highmore, J. S. COLE and E. C. CHILCOTT (*South Dakota Sta. Bul. 84, pp. 9–14*).—Tabulated data, with comments, are given for the yields of a number of varieties of macaroni wheat, barley, oats, and emmer. The rainfall during the early part of the season was very light, and many of the grains were seriously injured.

The yield of macaroni wheat ranged from 9 to over 20 bu. and averaged 14.65 bu. per acre. The season's experiments indicated clearly its great drought-resisting quality. Two varieties of emmer or spelt gave yields of 23 and 20 bu. per acre, respectively. Six varieties of oats were tested. One was a total failure; the other 5 gave an average yield of 31½ bu. per acre. The heaviest yield was made by Swedish Select oat—38.12 bu. per acre. Of 26 varieties of barley tested, 5 were total failures. The other varieties yielded from 10.62 to 27.50 bu. per acre. The latter yield was made by Minnesota No. 6.

A new method of sowing for the protection of winter grains, FALKE (*Deut. Landw. Presse, 31 (1904), No. 64, pp. 553, 554*).—A comparison between grain sown with the press drill and with the ordinary drill is reported and discussed. Grain sown with the press drill gave a better stem, a higher weight of plants and of the dried roots, favored tillering to a greater extent, and showed an increase in the height of plants as compared with the grain sown in the ordinary way. The results were quite marked, and this is considered due to a dry season.

Variety tests with different grains, T. REMY, P. EHRENBERG, and E. SIERIG (*Deut. Landw. Presse, 31 (1904), Nos. 25, pp. 215, 216; 26, pp. 225, 226; 27, p. 239; 28, pp. 245, 246*).—Variety tests with oats, spring wheat, and barley are reported. Among 22 varieties of oats from different sources, Svalöf, Ligowo, Duppau, and Hopetown were the most productive. Duppau is of medium quality, but the other 2 varieties are ranked as excellent. Beseler No. 1 proved a good straw producer, but stood low in the yield of grain. Beseler No. 2, Beseler No. 3, and Strube Schlanstedt stood up well, and are therefore considered suitable for irrigated fields or other conditions which tend to lodge the grain.

Seven varieties of wheat were sown April 9, and by July 23 all except Noë, Heine Bordeaux, and Red Mountain lodged completely. White Mountain led in the yield of grain and Red Schlanstedt in the yield of straw. White Mountain also gave the

best yield under irrigation. It is stated that Red Schlanstedt, Heine Bordeaux, and Noë, which have been derived from winter wheats, are not adapted to late sowing.

The barley was grown on a soil rich in nitrogen, which resulted in a complete lodging and a consequent loss in quality. Good yields were obtained, and Svalöf Chevalier was especially productive. The Imperial Barley stood up well, indicating a capacity to withstand lodging. Imperial Type A gave very promising results. In a series of irrigated plats the varieties all lodged and the results were not considered.

HORTICULTURE.

Report of the Department of Horticulture, F. A. Waugh and G. O. Green (*Massachusetts Sta. Rpt. 1903, pp. 154–172*).—An outline is given of the work of the year, including descriptive notes on 65 varieties of strawberries, and an account of cultural methods for this fruit.

Some data are given on the results of shipping apples in boxes, showing that this practice has proved profitable, and sometimes highly so. In one instance Gravenstein apples were shipped both in barrels and in bushel boxes the same day to the same dealer, the fruit being of like quality in each case. The apples sent in the boxes were wrapped. The barrels sold for $2 each and the boxes brought the same price, although they held only one-third as much fruit. This, however, was an extreme case, and such disproportionate prices have not usually been obtained, although it is believed that fancy fruit will always bring good prices when shipped in boxes. The use of boxes on a large scale is not recommended without considerable preliminary experiment on the part of the shipper.

A good yield of quinces was obtained, which sold at good prices. The quince orchard is located on a springy slope at the base of a hill, the soil being good, rich alluvium.

Horticultural department notes, N. E. Shaw (*Jour. Columbus Hort. Soc., 19 (1904), No. 3, pp. 98–100*).—Notes are given on the growth during the season of a number of vegetables. A liberal use of nitrate of soda on cabbage hastened its growth so that it was possible to market it 10 days in advance of the maturity of cabbage in the neighborhood. A return of $100 was secured from this crop on something over one-half acre during the last week in June.

The season's experience with Sparks Earliana tomato indicated that this variety, on account of its tender skin and scanty leaf formation, is not able to withstand the hot summer sun of the locality. The variety is a rapid grower, however, and does well in the early part of the season. It is thought that profitable returns might be obtained if the plants were started very early in the greenhouse. Of two other varieties grown, Livingston Magnus and Stone, the Stone variety produced the finest specimens of fruit in 1904, although the preceding season the reverse was true.

The importance and value of the horticultural industries of Ohio, V. H. Davis (*Jour. Columbus Hort. Soc., 19 (1904), No. 3, pp. 100–109*).—Statistics are given on the production in the State of vegetables, orchard products, forest products, small fruits, flowers and plants, grapes, nursery products, and nuts. While Ohio does not stand first in the Union in the production of any of these crops, it stands well up toward the top in the production of all. It ranks third in the production of apples and second in the value of its small fruit products.

Fertilization problems. A study of reciprocal crosses, M. B. Cummings (*Maine Sta. Bul. 104, pp. 81–100, pls. 4*).—In addition to a summary of previous work along this line, the author presents detailed results of his studies with reciprocal crosses of red currant and yellow plum tomatoes, and Golden Custard and Summer Crookneck squashes. The difficulty which has been experienced heretofore in securing reciprocal crosses between the red currant tomato (*Lycopersicum pimpinellifolium*)

and the red currant tomato (*L. esculentum*) was found to be due to the peculiar formation of the pistil of the red currant variety.

The pistil of this variety is considerably smaller than that of the yellow plum, and has the further peculiarity of being constricted and placed in a slight depression in the ovary. The pistil is so small and slender at this point that when the blossom is emasculated and the pistil thus deprived of the protection of the surrounding stamens, it was easily affected by changes of temperature and moisture which in most cases proved fatal.

When the ordinary methods of covering the flowers were employed it was found impossible to keep the pistil fresh in the receptive period long enough for the pollen of the yellow variety to do its work. When the whole plant was covered with bell jars, thus securing a better control of temperature and moisture conditions, successful crosses were made. The difficulty, therefore, which has been previously experienced in securing reciprocal crosses with these plants seems to be a mechanical one and due to the delicate structure of the pistil of the red currant variety.

In the case of squashes crosses were easily secured when Golden Custard was fertilized from the pollen of the Crookneck variety, but the pollen of Golden Custard would not act upon the pistils of the Crookneck variety. The author pollinated 284 pistils of the Crookneck squash with the pollen of Golden Custard. About one-third of this number were picked off at various stages for microscopical studies. The remainder were left on the vines as long as they remained intact. In the histological study of the pistils which were picked off it was found that pollen of Golden Custard germinated on pistils of Crookneck and usually penetrated nearly to the germ cell of the ovary. There it stopped growth. Fertilization did not occur. The reason for the failure appeared to be a refusal of the embryo of Crookneck to be impregnated by pollen spores of the Custard variety.

Some of the pistils which had been left on the vines matured fruits, and when these were cut open in some cases many seeds were found. Of the 200 pistils left on the vines, 18 well-formed fruits were obtained, and of these 18 fruits 5 produced fertile seeds. The experiments therefore seemed to indicate that "Golden Custard pollen varies in its degree of potency and shows all possible stages, ranging from perfect fertility to perfect sterility," as was shown "in the decay of Crookneck pistils when pollinated with Golden Custard, in microscopical sections of such pistils, in the partial and complete development of fruit and seed, and in the sterility and fertility of seed." A bibliography of 32 papers on plant breeding is included.

Culture of asparagus in warm countries, O. Labroy (*Jour. Agr. Trop., 4* (*1904*), *No. 39, pp. 259–264*).—This article summarizes the results which have been secured in a number of different tropical countries in the culture of asparagus. The conclusion is reached that asparagus succeeds in all those tropical countries where it is assured of a rest period in its growth, although the plantation is not as durable as in more temperate climates, and the young stalks are less valuable. In order to secure the best results it is necessary that the plants be cultivated in rich, deep soils and heavily manured and cultivated during their vegetative period.

The chayote (*Queensland Agr. Jour., 15* (*1904*), *No. 3, p. 625, pl. 1*).—It is stated that within the past 2 or 3 years this vegetable has become recognized by the general public in Queensland as an excellent table vegetable. It thrives remarkably well and is noted as one of the most prolific bearers among the Cucurbitaceæ. It is grown in large quantities also for feeding dairy cattle, pigs, and horses. Four hundred fruits have been gathered from a single vine in one season. No disease of any kind has been known to attack the plant in Queensland as yet. It is prepared by cutting the fruit in half, boiling it, and serving with pepper, salt, and melted butter.

Facts about ginseng culture for fruit growers, G. C. Butz (*Pennsylvania State Dept. Agr. Rpt. 1903, pp. 800–803*).—This paper is in part a summary from the author's bulletin on this subject (E. S. R., 14, p. 861). A word of caution is added

regarding ginseng seeds. These should never be allowed to dry out, as they lose vitality quickly by drying. They may be tested by throwing in water; those that float are worthless.

Recently considerable Japanese ginseng seed has been imported and sold as American seed because it is cheaper. The Japanese seed produces an inferior variety of ginseng. It can be detected by the fact that it has ridges over its surface which are not possessed by the American seed. Samples of seed which were claimed to be of Manchurian origin were sent to the author for examination, but in every case have been found spurious.

The cultivation of mushrooms, B. M. Duggar (*U. S. Dept. Agr., Farmers' Bul. 204, pp. 24, figs. 10*).—This bulletin is designed to take the place of an earlier number of this series (E. S. R., 9, p. 357). It contains directions for the commercial culture of mushrooms, with an account of the insects and diseases affecting them, and directions for making spawn.

The author advocates the tissue method of spawn culture which is described essentially as follows: Test tubes or large-mouth bottles are filled with fresh stable manure or with a compost and then sterilized. This material is then inoculated by selecting from a bed of vigorous growing mushrooms a variety which has proved unusually prolific. With a sterilized scalpel and forceps, the stem is broken off and the outer skin peeled off. Small bits of the tissue of the mushroom are then taken and used to inoculate the manure in the sterilized bottles.

It has been found that within the course of a week, or sometimes within 2 days, these bits of tissue will send out a small growth of mycelium which spreads to all parts of the tube or bottle within 3 or 4 weeks. This material can then be used as pure culture virgin spawn for inoculating bricks. This method of producing spawn has been found to be commercially practicable, and 3 varieties of mushrooms named, respectively, Alaska (a white sort), Bohemia (a brown sort), and Columbia (an intermediate or cream-gray sort), have been developed which can be reproduced true to type.

Early garden peas, N. E. Hansen (*South Dakota Sta. Bul. 85, pp. 8*).—In cooperation with this Department the author tested 153 varieties of garden peas and the results as regards the yields, period of growth, size and shape of pods, quality of peas, etc., are tabulated for 80 of the earlier sorts. The earliest varieties were Alaska, Extra Early, Thorburn Extra Early Market, First of All, First and Best, Pedigree Extra Early. Some of the prolific late sorts of fine quality were Abundance, Admiral, Stratagem, Everbearing, Bliss Everbearing, and Sutton Satisfaction.

Recent cultural experiments with Pé-tsaï, J. Curé (*Rev. Hort., 76 (1904), No. 16, pp. 387, 388*).—The author recently conducted some experiments with Chinese cabbage, Pé-tsaï, to see if a crop could not be grown without running to seed. Three different seedings were made on the same day. The first was made in a very warm bed with the idea of burning the first sprouts that germinated. They did not come up until after those sown in the cold soil were showing. These plants were pricked out when the cotyledons were well developed. Thus treated it was found necessary to water them frequently.

None of the plants seeded in the hot soil obtained full development. Two plants developed to about $\frac{3}{4}$ of their size, and in no case was the rudiment of a floral stem observed. A second seeding was made in a bed less warm than the first. At the end of 48 hours all the seeds had shown a good state of vegetation. These plants were not pricked out before setting in permanent places. It was from this seeding that the best results were obtained. Some of the fully developed plants obtained a height of 55 to 60 centimeters with a head weight in some cases of 3 to 4 kg. In no instance were seed stalks produced with this lot of plants.

With the third seeding made in cold soil practically all of the plants went to seed and none produced heads. From these experiments it is believed that in order to

produce good Chinese cabbage it will be necessary to give it the same care as curled chicory or turnips in forced culture. Some suggestions are given on the preparation of this vegetable for the table.

Notes on varieties of tomatoes, V. H. DAVIS (*Jour. Columbus Hort. Soc., 19* (*1904*), *No. 3, pp. 114–116*).—Notes are given on a number of varieties of tomatoes tested at the station during the season. Sparks Earliana proved a very satisfactory sort. The fruit is of good size, fairly smooth, and of excellent quality for an early tomato. Objections to the fruit were its rather open growth and its tendency to scald.

A new tomato (*Gard. Chron., 3. ser., 36* (*1904*), *No. 925, p. 198, fig. 1*).—A description is given of a new tomato, "The Reverend Laycock." It is an especially handsome tomato, characterized by great fleshiness, small number of seeds, firm skin, and excellent flavor. It has a shining mahogany color when ripe. It appears to be a heavy bearer of good-sized fruits.

Orchard studies—XVI. The composition of apples, W. B. ALWOOD and R. J. DAVIDSON (*Virginia Sta. Bul. 143, pp. 283–299*).—The authors present the results of analyses of 10 varieties of summer apples, 13 of autumn apples, 19 of winter apples, and 7 of crab apples, with reference to the amount of juice and pomace, and the composition of the juice with reference to solids, sugar, acids, tannin, and specific gravity, and the composition of the pomace with reference to moisture, ash, sugar, acids, and tannin. The determination of moisture, solids, nitrogen, ash, phosphoric acid, potash, and lime is also given for a few of the different classes of apples noted. The purpose of the work is to secure accurate data as to the quality of the different varieties and their relative value for purposes of manufacture of secondary products. It is also hoped that the data may be found valuable in crossbreeding work in the future.

Considering all the results together, the average water content of the whole fruit varied in the experiments from 80 to about 86 per cent of their total weight. With an 80-ton hydraulic press it has been possible to obtain only about 74 per cent of the weight of the fruit as juice. It is considered that in practice 70 per cent is a very high average. The amount of juice recovered in the summer varieties of apples examined averaged 48.91 per cent. Omitting two varieties which were specially poor in juice, the average was 53.20 per cent. The juice obtained from autumn varieties averaged 53.92 per cent of the weight of the fruit; of winter apples, 52.16 per cent, and of crab apples, 57.31 per cent.

The crabs thus show the highest percentage of juice of any of the different groups of apples examined. The average total sugar content of the juice of summer varieties was 9.53, autumn varieties 10.66, winter varieties 11.43, and crab apples 11.71 per cent. The amount of sugar remaining in the pomace varied from 4.16 per cent in the case of summer apples to 4.38 per cent in autumn apples. Pomace of winter apples contained 4.29 per cent of sugar, and of crab apples 4.26 per cent. It is believed that the sugar content in the pomace could be extracted by exhaustion with warm or cold water in some such manner as is followed in beet-sugar diffusion batteries. The weak must, or juice, thus recovered could be used for diluting richer juice intended for vinegar stock. The value of pomace for stock feed when ensiled is also pointed out.

The apple in Oregon, E. R. LAKE (*Oregon Sta. Bul. 81, pp. 32, pls. 8, map 1*).—The author discusses the early history of apple growing in Oregon, including an account of the rise and decline of early planted orchards, and gives directions for planting and caring for orchards in the State at the present time.

Planting the apple orchard, L. B. JUDSON (*Idaho Sta. Bul. 43, pp. 321–351, figs. 15*).—Popular directions are given for planting and growing orchards, from the selection of the site to the harvesting of the fruit.

Picking and handling winter apples, J. S. WOODWARD (*Rural New Yorker, 63* (*1904*), *No. 2855, p. 745*).—Directions are given for modern methods of picking and

handling apples in the orchard. Relative to the storage of apples in cellars, the author states that it has been found that the apples kept much better if stored in bulk in the cellar than if put into barrels, and the larger the bins and more apples that are put together the better they keep. The author has never had apples, even Greenings, scald when stored in bulk in large bins. Apples which are intended for barreling and immediate shipment are barreled as rapidly as picked, instead of being allowed to lie and sweat, as was at one time thought desirable.

Keeping quality of apples, F. H. HALL (*New York State Sta. Bul. 248, popular ed., pp. 11*).—This is a popular edition of New York State Station Bulletin 248, by S. A. Beach and V. A. Clark, on New York apples in storage, previously noted (E. S. R., 16, p. 50).

A horticultural freak (*Orange Judd Farmer, 37 (1904), No. 16, p. 359, fig. 1; Amer. Agr., 74 (1904), No. 16, p. 324, fig. 1*).—This is a discussion of the merits of the seedless apple, an illustration of which is given showing a cross section. It is pointed out that while a certain class of apples may be seedless, they contain the usual "core" or carpels. This class of apples, while they have long been known, have not been disseminated to any extent, largely on account of their poor quality.

The claim that these apples are bloomless relates only to the petals; stamens and pistils are present, and are just as liable to injury by late spring frost as are blossoms with petals. The blossom end of the apple, instead of being closed, is more or less open, and this opening extends a considerable distance toward the center of the fruit.

Fruit growers are cautioned against paying fancy prices for seedless apple stock, for at present there is nothing to warrant planting them, in a commercial way at least.

The western sand cherry, N. E. HANSEN (*South Dakota Sta. Bul. 87, pp. 64, pls. 20*).—The sand cherry, *Prunus besseyi*, is a native northwestern prairie fruit which is being cultivated on an extensive scale at the station for the purpose of meeting the demand for a hardy cherry or a satisfactory substitute for it. It is a small fruit and not an orchard fruit, the plants varying from 1 to 4 ft. in height. In cultivation it is recommended that the plants be set 3 ft. apart in rows 6 ft. apart. The plant is perfectly hardy throughout the Northwest. The wild fruit is exceedingly variable in size and quality, but all of it is acceptable for culinary uses. Up to 1903 the author had grown 47,397 sand cherry seedlings. Of this number 31,897 were selected for fruiting and for use as stocks, and from these over 100 varieties have been selected and are now under propagation for preliminary trial.

"Some of these bear fruit from $\frac{3}{4}$ to $\frac{7}{8}$ of an inch in diameter, and of quality acceptable for eating out of hand. It hybridizes readily with several other members of the genus. The fruiting of our numerous hybrids with Japanese plums, native plums, *Prunus simoni*, peaches, nectarines, cherries, and other species is awaited with interest. Some of these hybrids are combinations of at least three species.

"Seedlings fruit well the third year, and under favorable circumstances the second year from seed. When worked on strong native plum (*Prunus americana*) stocks, fruit is borne in abundance upon shoots one year old from the bud or graft. The species responds readily to cultivation. . . . The third generation is decidedly more variable than the first.

"The fruit averages larger when the sand cherries are budded on native plum stocks. . . . It also appears probable that when grown on native plum stocks sand cherries bear better on heavy soils than when on own roots. The plants are remarkably productive when young or on young shoots, but for older plants some system of renewal pruning may be advisable. This species deserves special attention as a dwarf stock for peaches, apricots, Japanese and native plums. Tame cherries unite with difficulty. The past three seasons peaches of normal size have been raised at this station from trees on sand-cherry stocks. These were trees grown in pots, tubs, and boxes, wintered in a cool cellar, and fruited under glass. For orchard purposes

plum trees on this stock must not be high-stemmed, as they get top-heavy and lop over when bearing a heavy crop of fruit. If used at all it must be as a bush with several stems. The trees are not dwarfed in nursery. Evidently the trees should be headed back annually, at least until in heavy bearing, to keep them properly dwarfed. The fruit is fully up to standard in size and quality."

The bulletin contains a complete account with many illustrations of the progress made with this fruit at the station, and also presents a summary of the results of the work done with the fruit at other stations and by nurserymen and growers in neighboring States. It is predicted that "the western sand cherry will be found of great value in the commercial propagation of some of the stone fruits" and that from it "will be developed by selection a race of bush fruits with fruit equal to California cherries in size and of a quality acceptable for table use." There will also be developed from it "a race of hybrid fruits of a new type by hybridizing with choicer fruits; these 'new creations' will be hardy and fruitful on the most exposed prairies."

The "Compass" cherry, a hybrid between the sand cherry and Miner plum originated by H. Knudson, of Springfield, Minn., is illustrated. The fruit is intermediate in season between the sand cherry and plum, very productive, and the flavor sprightly and pleasant. It is considered well worthy of a place in the home garden.

Breeding hardy fruits, N. E. HANSEN (*South Dakota Sta. Bul. 88, pp. 32, pls. 29*).—The author briefly summarizes the work in plant breeding now under way at the station. Numerous cuts are given illustrating his method of work and some of the results obtained with the different fruits. Up to June, 1891, the author had grown seedling fruits as follows: Sand cherry, 8,400; plum, 4,000; grape, 5,000; wild strawberry, crossed with tame, 5,000; native strawberry, 1,000; pin cherry, 25; choke cherry, 360; golden currant, 200; black currant, 2,200; buffalo berry, 180; gooseberry, 425; wild raspberry, crossed with tame, 200; pure native raspberry, 40, a total of 27,030 seedlings.

The work has steadily increased since that date and at the time of writing the number of seedlings had reached fully a quarter of a million. The work is being conducted primarily along two lines, first, by selection from a large number of seedlings, and second, by crossing or hybridizing with cultivated varieties. In the fruit-breeding work at the station perfect hardiness of plant is the first consideration. An effort is being made to extend the cherry, peach, and apricot belt north to the Manitoba line. In the breeding work with vegetables earliness combined with satisfactory yield is the end aimed at.

How to prevent decay of our citrus fruits (*Florida Agr., 31 (1904), No. 39, p. 611*).—This is a reprint of a paper read by T. J. Ashby before the Pasadena Lemon Growers' Association. The author estimates that during the past 8 years the amount of decay for all classes of citrus fruits which have been shipped was 8 per cent. In figures, this represents a loss during this period of about four and a quarter million dollars.

As a means of prevention the author suggests top working with buds taken from trees which produce firm, marketable fruit which will stand shipment. He believes also that in the matter of orchard management the development of the fruit should be retarded rather than forced, since quick growth and rapid decay are terms which are closely correlated.

The author points out the value of dry air in the shipment of fruits and suggests the use of an electric fan with a shaft which would force air to the center of the rooms or cars in which the fruit was kept.

Propagation and marketing of oranges in Porto Rico, H. C. HENRICKSEN (*Porto Rico Sta. Bul. 4, pp. 24, pls. 6, figs. 4*).—A popular discussion of this subject.

Experiments in the aeration and green manuring of the soil in fruit culture, G. BIESENBACH (*Deut. Landw. Presse, 30 (1903), No. 87, p. 752*).—Many orchards in certain parts of Germany do not grow well and are unproductive. The

author conducted some experiments to determine the effect of aeration of the soil in such localities on growth of fruit trees. In transplanting nursery trees to the orchard a hole was dug from 1 to 1¼ meters in diameter and 1½ meters across. Instead of having the hole come to a point at the bottom, as is usually the case in transplanting trees, it was actually made wider at the bottom than at the top. In the case of sandy land, where this kind of a hole could not be dug without danger of caving in, the hole was made wider at the top and the walls dug straight down.

After digging the holes they were allowed to remain open for a few weeks. They were then filled about one-quarter full with brushwood, twigs, leaves, and such material. A layer of earth was then covered over this material and the hole again left for a period of several weeks, after which it was filled up with alternate layers of fine soil, brush, half-rotton wood, and humus. Trees planted in holes thus made have uniformly made a remarkably good growth, and the strong roots thrown out have been able to penetrate the bottom and side walls of the holes into the harder layer of earth.

Excellent results are also reported from the use of hairy vetch, crimson clover, and red clover as cover crops in the orchard.

Results of soil aeration with orchard fruits and its value in general culture, Causemann (*Deut. Landw. Presse, 31 (1904), No. 72, pp. 619, 620*).—The author notes an experiment in the planting of 120 fruit trees, partly along highways and partly in an orchard. The aeration of the soil was secured by digging holes about 1¼ meters deep and a little wider and filling the same with alternate layers of brushwood and soil. All the trees thus treated have made a remarkably good growth in every situation. This method of setting out trees, it is believed, promises much for certain orchard sections of Germany, where unsatisfactory results are now being secured. Some other data are noted showing the value in general of deep preparation of the soil for growing crops.

Pruning, fertilizing, and thinning, J. H. Funk (*Pennsylvania State Dept. Agr. Rpt. 1903, pp. 791–796*).—Directions based on a number of years of successful experience are here given for the pruning, fertilizing, and thinning of orchard fruits.

For transplanting in the orchard the author prefers 1-year-old peach trees, and apple trees not older than 2 years. The trees are pruned to whips and cut off at a uniform height of 18 in. to 2 ft. When the young shoots have grown about an inch all buds below the sixth top ones are rubbed off. Heading in is regularly practiced to induce stockiness and early fruiting. Well-rotted stable manure is recommended during the early growth of the trees. In the author's orchard 6 to 8 year old trees average 6 to 8 in. in diameter, and he finds no difficulty in securing a growth of an inch in diameter each year.

Reports of the pomologist, C. T. Fox (*Pennsylvania State Dept. Agr. Rpt. 1903, pp. 233–243, 536–543*).—Reports are here given for the years 1902 and 1903, on the production of orchard and small fruits in the different sections of Pennsylvania. The Kieffer is grown more largely than any other pear in Pennsylvania. The Numbo and Paragon varieties of chestnuts have been grafted on native trees with much success. The grafts bear fruit in 3 years and the nuts are much larger than the native sorts and command double their price in the market. The varieties of apples, pears, cherries, grapes, peaches, quinces, and strawberries of note which have been originated in the State are mentioned briefly, with an account of their origin. The introduction of Japanese varieties of plums in Pennsylvania has given new life to that industry.

Fruit-growing statistics of Erie County, L. G. Youngs (*Pennsylvania State Dept. Agr. Rpt. 1903, pp. 715, 716*).—Erie County in Pennsylvania borders on Lake Erie. It contains 50,000 acres of grape land, of which 6,000 acres have been planted. The normal annual production of grapes is 1,800 carloads, valued at $600,000. The annual value of berries and other small fruits is $300,000. About 400,000 bu. of

apples are produced in the county, "95 per cent of which are only fit for cider." The value of the fruit and produce used by canning factories is placed at $150,000.

Plowing v. mulching (*Amer. Gard., 25 (1904), No. 505, p. 662*).—An account is given of an experiment in cultivating v. mulching peach orchards. The orchard in question was that of J. H. Hale, in Connecticut. It is stated that the mulched trees made a growth that many people would have been satisfied with, but much better results were secured by cultivation. The cultivated trees made a better growth, and the leaves were larger and of a deeper green color. It was an easy matter to pick out by appearance the cultivated from the mulched trees in the different sections of the orchard.

Cooling peaches before shipping (*Orange Judd Farmer, 37 (1904), No. 16, p. 359*).—As the results of investigations by G. H. Powell of this Department, in Georgia, it is stated that if peaches are cooled quickly to about 40° before being loaded in refrigerator cars, they will carry to the most distant northern markets without loss. "Nine full carloads were included in the cooling tests, and check cars cooled in the ordinary way accompanied them to New York and New England markets. The cooled fruit arrived in practically the same condition in which it left the orchard, in uniform condition from the bottom to the top of the car. In the check cars there was as much as 30 per cent soft and decayed fruit in the top layers of peaches. In some cases the fruit was sold after 14 days in the cold car in prime condition." It is believed that the investigations indicate that a large proportion of the usual losses in transit of the peach can be overcome if the temperature of the fruit can be reduced quickly after picking. The body of ice in an ordinary refrigerator car does not reduce the temperature quickly enough to check ripening, and the fruits deteriorate at the top, where the temperature is highest.

Cold storage for fruit (*West Indian Bul., 5 (1904), No. 2, pp. 117–134*).—This article is made up largely of a series of interviews with the managers of important cold-storage plants in the United States on the methods followed in their work in the cold storage of fruits.

Graft hybrids (*Gard. Chron., 3. ser., 36 (1904), No. 926, pp. 217–219, figs. 5*).—A review is given of the work of L. Daniel in producing graft hybrids, and of earlier work of a similar nature by others. A number of cuts of graft hybrids illustrate the article.

Coffee and coffee culture, C. B. HAYWARD (*Sci. Amer., 91 (1904), No. 12, pp. 194, 195*).—A brief account of the early history of coffee, and the various stages of development from flowering to the manufactured product.

Coffee planting in Porto Rico, J. W. VAN LEENHOFF (*Porto Rico Sta. Circ. 5, pp. 14, figs. 6*).—Popular directions are given for the planting and management of coffee plantations in Porto Rico. The article is preceded by an account, by F. D. Gardner, on the experimental work now being carried out at the station with coffee. Special attention is being paid to planting at different distances and to different cultural methods. Experiments to control the coffee-leaf miner, by picking and destroying all infested leaves, have been made on several occasions, but the indications are that the task is too great to be practicable. The circular is also issued in the Spanish language.

Comparative study of different methods of pruning, B. CHAUZIT and G. BARBA (*Rev. Vit., 22 (1904), Nos. 554, pp. 92–95; 555, pp. 122–126*).—The authors conducted a series of experiments extending over a number of years with different methods of pruning vinifera varieties of grapes to determine the effect on yield and quality of the wine produced. The results obtained are tabulated as regards yields during 9 seasons, and the composition of the must as regards sugar, acid, alcohol, extract, ash, etc.

The final conclusions regarding the matter are as follows: Long-pruned vines trained on wires are more prolific, other things being equal, than vines pruned and

trained in goblet form, and manifest after 9 years' trial no sign of enfeeblement. Fruit from long-pruned vines ought to be harvested 15 to 20 days later than fruit from vines subject to ordinary short pruning, in order to improve the quality of the wine produced. Even when long-pruned vines are harvested later they never produce as perfect a quality of wine as short-pruned vines, because the fruit does not reach such perfect maturity. The total amount of sugar material harvested per hectare is much greater in long-pruned vines than in those pruned short.

The growing of raspberries for profit, P. HARRIS (*Pennsylvania State Dept. Agr. Rpt. 1902, pt. 2, pp. 123–127*).—The author describes his successful method of growing raspberries for profit. Details are given as regards methods of planting, pruning, and varieties. The Loudon has been adopted as the best of a number of varieties of red raspberries tested. The Kansas is considered the most satisfactory of the black varieties. It leads as regards yield and profit.

Strawberry handbook (*New York: German Kali Works, pp. 32, figs. 9*).—Popular directions are given for the planting, manuring, and general care of strawberries. Several tables are included which show the composition of the more common commercial fertilizers and manures.

Report on latices and rubber from Rhodesia, W. R. DUNSTAN (*Rhodesian Agr. Jour., 2 (1904), No. 1, pp. 23–25*).—Analyses are given of a number of samples of latices from different rubber-producing plants in Rhodesia, and also of a sample of rubber from the Umtali district.

Rubber coagulating methods in Central Africa, G. VAN DEN KERCKHOVE (*India Rubber World, 31 (1904), No. 1, pp. 5–7, figs. 8*).—A number of different methods used by the natives in Central Africa for coagulating rubber are briefly described. Supplementing the article is a paper on the coagulation of root rubber, republished from a recent work by De Wildman and Gentil.

A grand novelty (*Gard. Chron., 3. ser., 36 (1904), No. 927, pp. 240, 241, fig. 1; Sup., pl. 1*).—An account is given of the plant *Meconopsis integrifolia*, which has lately flowered in several establishments in England for the first time. The plant is native in Tibet, where it grows at elevations above 11,000 ft. Its upward limit appears to be about 15,500 ft. The flowers in Tibet are 8 to 10 in. in diameter and of a beautiful yellow color. There are about 11 flowers on each plant in Tibet, but under cultivation 4 to 5 flowers appear to be the normal number. The petals are normally 5 in number and borne erect something like a tulip. It is believed that this flower will prove among the most valued Papaveraceous species in cultivation. A botanical description is given of the plant.

FORESTRY.

Forest resources of Texas, W. L. BRAY (*U. S. Dept. Agr., Bureau of Forestry Bul. 47, pp. 71, pls. 8, figs. 2, maps 3*).—After briefly describing the conditions affecting the character and distribution of forest growth in Texas and the natural divisions of the State, a discussion is given of rainfall, nature of soil and rock, temperature, sunlight, winds, etc., as factors in determining forest distribution in Texas. The different forest areas are classified and their chief characteristics described. Notes are given on the commercial value of the different forest areas, forestry practices, etc., and suggestions for the conservative management of lumbering the remaining timber.

The author says that in spite of the hopeful beginning that has been made in the private management of the long-leaf pine, without State aid it will be impossible to protect the public interests affected by forest destruction. The long-leaf pine lands under present conditions are practically without reforestation, and on loblolly and short-leaf pine lands the reforestation is rapid enough, but in most places the pine is replaced by scrub oak.

The author believes that the State should assist by promoting management by private owners and by itself undertaking the management of forests on State lands. He claims that forest preservation, in the interests of the State of Texas as a whole, can be obtained only by the adoption of a definite State policy which would not only meet the present needs, but would include assistance to private management and the establishment of State reservations. The bulletin concludes with a list of the valuable timbers native to Texas, with notes on their distribution, habits, and uses.

The forests of the Hawaiian Islands, W. L. HALL (*U. S. Dept. Agr., Bureau of Forestry Bul. 48, pp. 29, pls. 8*).—This is a report on the forests of Hawaii, based on the recent reconnoissance of the forests, and contains recommendations which form the basis of a forest policy which is being put in effect by the Territorial government. The bulletin is an elaboration of a previous publication (E. S. R., 15, p. 778).

Exhibit of a forest nursery at the Louisiana Purchase Exposition, G. PINCHOT (*U. S. Dept. Agr., Bureau of Forestry Circ. 31, pp. 7, figs. 2*).—As a portion of the outdoor exhibit of the Bureau of Forestry at the Louisiana Purchase Exposition, a demonstration is made of forest nurseries in which different methods of seeding for coniferous and deciduous trees are described, as well as the use of screens for suitable shade, etc.

Exhibit of forest planting in woodlots at the Louisiana Purchase Exposition, G. PINCHOT (*U. S. Dept. Agr., Bureau of Forestry Circ. 30, pp. 11, fig. 1*).—In order to illustrate different methods of forest planting in woodlots, the Bureau of Forestry has prepared, as a part of its outdoor exhibit at the Louisiana Purchase Exposition, a series of plats planted with different species and mixtures suitable for different parts of the United States. The woodlot plantations are made primarily for the production of fuel and timber, and the selection of species is based on this fact. A description is given in tabular form of the different woodlot plantations.

Forest conditions of the San Francisco Mountains forest reserve, Arizona, J. B. LEIBERG, T. F. RIXON, and A. DODWELL (*U. S. Geol. Survey, Prof. Paper 22, pp. 95, pls. 7*).—This is a report on the forest conditions of the San Francisco Mountains reserve, in which the various physical features are described and detailed notes given on the character of the forests. The reserve contains nearly 2,000,000 acres, and the report is based upon a critical examination of 812,500 acres. The different zones or types of arborescent growth are described, and notes given on the undergrowth, ground cover, etc. The principal species of trees are the yellow pine, which supplies by far the greatest amount of timber, followed by red fir, white fir, Engelmann spruce, and other species of less abundance and value.

Notes are given on the various agencies through which the forests are being destroyed. Logging operations have been carried on in most of the forest area in the central part of the reserve, in some places the timber having almost all been cut. The effect of grazing, especially sheep herding, is described, and also the injury which has been caused by forest fires. The reproduction of species, particularly the yellow pine, is very deficient, and the yellow pine is said to be as a rule past its prime and in a state of decadence. The grazing value of the reserve is commented upon, the principal species of grasses being enumerated. A detailed description is given of the different townships embraced in the reserve.

The disappearance of the chestnut in France (*Bul. Mens. Off. Renseignements Agr., 3 (1904), Nos. 1, pp. 11–29; 2, pp. 163–177*).—The importance of the chestnut tree in France is commented upon and official data given relating to the value of its products. These increased to about 1890, from which time there has been a steady decrease in the production and value of the products. This is attributed to the destruction of the trees through various means. One of the most important is the cutting of the trees for the bark, which is rich in tannin.

A second and very important cause is a disease due to an unknown cause which produces exudations on the lower part of the trunk and roots. A review is given of the various attributed causes of this disease and the opinions of a number of investigators are summarized. Chapters are given on the utilization of the bark and wood of the chestnut, and suggestions made for its more conservative management. The paper concludes with a list of about 50 references to the literature of the subject, which is appended as a bibliography.

On the reestablishment of chestnut forests, A. PRUNET (*Bul. Mens. Off. Renseignements Agr., 3 (1904), No. 5, pp. 536-541*).—Attention is called to the destruction of chestnut trees through the disease known as "black foot" or "ink disease." For the reestablishment of the forests the author suggests planting trees that have been grafted upon resistant stock, and for this purpose he recommends grafting on other species of chestnut, on the American chinquapin (*Castanopsis chrysophylla*), and also upon certain species of oak which have been demonstrated as suitable stock for that purpose.

The timber of the Edwards Plateau of Texas, W. L. BRAY (*U. S. Dept. Agr., Bureau of Forestry Bul. 49, pp. 30, pls. 5, map 1*).—This bulletin gives an account of the timber of the Edwards Plateau of Texas, and discusses its relation to climate, water supply, and soil. After describing the region, which lies east of the Pecos Valley and north of the Rio Grande River, an account is given of its climatic conditions, water supply, etc., and the vegetation of the region is described at some length.

Progress report of forest administration in Coorg, C. D. MCCARTHY (*Forest Dept., Coorg, India, Rpt. 1902-3, pp. 28*).—A report is given on the forest administration for the years 1902 and 1903, with notes on the extension of State forests, their management, exploitation, gross yield of products, and the financial returns. The reserved and protected forests amount to nearly one-third of the entire area of the district.

Forestry in Japan (*Japan in the Beginning of the 20th Century. Tokyo: Imperial Japanese Commission to the Louisiana Purchase Exposition, 1904, pp. 224-288*).—The forest area of Japan is said to be about 56,563,000 acres, or 59 per cent of the total area of the islands. Of this area 21 per cent is pure coniferous forest, 25 per cent deciduous, 45 per cent mixed, and the remainder thinly stocked or waste lands. The bamboo areas, which form a feature in the forest system of Japan, are of extremely limited extent, and are said to show little signs of enlargement in the near future. A description of them has therefore been omitted.

The ownership of the forests and relative extent of different classes are given as follows: Government forests 32,156,000 acres, imperial forests 5,122,000 acres, and private forests 19,281,000 acres. The distribution of the forests, sylvicultural features, etc., are described, and notes given on the more important species of trees found in the different forest zones. The various systems of management are described and the results of elaborate investigations which have been inaugurated by the government for the study of forest conditions and improvements are shown.

In the government forests rotations of from 40 to 200 years have been adopted, dependent upon the species grown, and private owners are being urged to adopt similar methods. Encouragement is given to public and private forest planting so as not only to reproduce the forest as it matures, but also to replant extensive areas which were deforested after the political restoration. The only figures available are for the government and imperial forest plantings for the decennial period ending 1901. During this time there was an extension of the forest area by 2,805,000 acres.

The financial returns from the state forests for the year 1901 were in excess of $1,000,000, rating the Japanese unit of value at 50 cts. The tables given show a progressive net profit for the time covered, as well as an increased revenue per unit of area.

The management of the state forests is conducted by 16 major and 325 minor forest officers, organized under a Bureau of Forestry of the Department of Agriculture and Commerce. Other systems of management are permitted, a considerable number of areas being under local control.

Brief notes are given on forestry education and legislation. The first school of forestry, the Tokyo Dendrological School, was established in 1882, and at present there are 62 institutions of various grades in which instruction in forestry is given.

Forestry in the south of Ireland, R. H. KEANE (*Agr. Students' Gaz., n. ser., 12 (1904), No. 1, pp. 17–22*).—Descriptions are given of the forests of the south of Ireland, a region which was formerly completely forested, but which has suffered very materially from the removal of the timber and destruction of the forests. At present it is said that only 1.5 per cent of Ireland is wooded, the total area of forest being about 308,000 acres. This area embraces larch 46,000 acres, fir 34,000, oak 26,000, spruce 15,000, pine 2,500, beech 10,000, ash 7,000, elm 3,300, sycamore 3,000, and mixed forests 159,000.

Attention is called to the rapidity with which a number of species of forest trees grow when given proper attention, and suggestions given for future plantings. The prevailing forest crop is said to be a mixture of larch and Scotch fir, with a considerable amount of scrub oak, which is desirable only for fire-wood. The commoner varieties of trees and their suitability as regards soil and climate are described.

Review of forestry legislation for 1902, G. B. SUDWORTH (*New York State Library Bul. 80, pp. 839–843*).—During the period covered by this review it is said that 7 States enacted forest legislation, of which only 4 could be properly classified as forest laws. Of these, the laws of New York, providing for the establishment of a State park, and the New Jersey fire law are noteworthy. The provisions of these laws are reviewed and commented upon at some length. Other laws briefly reviewed are those passed by the legislatures of Ohio, Rhode Island, and Louisiana.

Practical notes on forestry for New South Wales, J. H. MAIDEN (*Agr. Gaz. New South Wales, 15 (1904), No. 4, pp. 341–344*).—Notes are given on the selection and propagation of forest tree seeds, means of testing, etc., and attention called to the necessity of rejecting inferior species in planting. The author describes the preparation of the soil for nursery beds, and gives directions for the care of the seedlings. The propagation of trees by other means than by seeds is described.

Forest conditions of the Black Mesa forest reserve, Arizona, F. G. PLUMMER, T. F. RIXON, and A. DODWELL (*U. S. Geol. Survey, Prof. Paper 23, pp. 62, pls. 7*).—This report was prepared by the first of the above-mentioned authors from notes made by the other two. The Black Mesa forest reserve contains approximately 1,783,000 acres, and extends in irregular strips of land from central Arizona in a southeasterly direction to the New Mexico boundary. The general topography of the region is described, as well as its drainage, water supply, lumbering operations, etc.

The lands of the forest reserve are classified as timbered area 80.7 per cent, woodland 14.04 per cent, timberless 5.02 per cent, and burned and logged area 0.24 per cent. The dominant species of timber trees of the reserve are the yellow pine, followed by Engelmann spruce, white pine, and red and white fir. In addition to the above species there is a considerable amount of oak, juniper, and cypress, which is of value for fuel.

Descriptions are given of the different species of trees, and notes on the rate of growth of the principal timber species. The report concludes with detailed descriptions of the townships embraced in the reserve.

Street trees and gas (*Amer. Gard., 25 (1904), No. 503, pp. 624, 625, fig. 1*).—Attention is called to the damage frequently suffered by street trees, which is attributed to the effects of illuminating gas, and quotations given from the report of the forester of Yonkers, N. Y., in which a number of instances are cited where trees were undoubtedly destroyed by leaks in gas mains.

The hardy catalpa, W. GILL (*Jour. Agr. and Ind. South Australia, 7 (1904), No. 11, pp. 614-616, pl. 1*).—A description is given of the hardy catalpa as a forest tree, particular attention being called to a number of plantations in parts of Australia. These plantings were made along small streams in rich soil, and the growth has been exceptionally rapid.

The results obtained in Australia are contrasted with those obtained in the United States, as shown by the publications of the Bureau of Forestry, some of the experiment stations, etc., and the author concludes that the growth of the trees in South Australia suffers little by comparison with the trees as grown in the United States. Attention is called to one important difference, however, that is, that while the tree in this country grows over a large area and in many kinds of soil, in South Australia it was found to succeed only on selected sites in close proximity to a permanent water supply.

Planting red cedar (*Oklahoma Sta. Rpt. 1904, pp. 54-56*).—Directions are given for the gathering of the seed of the red cedar, its preparation for planting, and subsequent care. The best results seem to follow the storing of the seeds in moist sand, and as they do not germinate until the second spring after planting, they should be protected against excessive drying during the summer. Notes are also given on Arbor Day as observed in Oklahoma, and a list of desirable trees for planting is given.

White oak and other southern woods (*Tradesman, 52 (1904), No. 2, pp. 73, 74*).—Notes are given on a number of species of oak which in the lumber market are frequently substituted for the true white oak. The species described are the basket oak (*Quercus michauxii*), chestnut oak (*Q. prinus*), and the chinquapin oak (*Q. prinoides*). The timber characteristics of these different species are described, and their differences when compared with white oak are contrasted. In addition notes are given upon a number of other species of oak, gum, and other timber trees.

Cross-tie forms and rail fastenings, with special reference to treated timbers, H. VON SCHRENK (*U. S. Dept. Agr., Bureau of Forestry Bul. 50, pp. 70, pls. 5, figs. 71*).—The treatment of ties used in railroad construction to preserve them against decay has made it possible to introduce new forms, a number of which are described and discussed. The relative value of different forms, the value of ties cut from live and dead timber, the desirability of decreasing the number of ties used per mile of track, and new types of ties are all discussed.

The author concludes that the present classification into first class, second class, etc., is not justified, and suggests a grading based on a certain definite-sized tie. Under the present system of management it is not deemed desirable to decrease the number of ties now laid per rail length. Triangular ties, which have been exploited to some extent, are not considered desirable and should not be used, as they are said to yield less bearing surface on the ballast than other forms.

Where tie plates are used on treated timbers of inferior grade, the requisition of an 8-inch top-bearing surface is believed to be wasteful. The half-round tie, which is described, is believed to be advantageous from a mechanical standpoint, as it is said to give greater bearing surface per mile and a more stable track, and at the same time it is more economical of timber. Experiments are in progress to test the practicability of sawing ties of this form in large numbers, and their value is believed to be worthy of trial.

The author takes up the different forms of rail fastenings, discussing spikes, screw spikes, etc., at considerable length. The best form is believed to be a screw spike now in use on the French Eastern Railway. This screw combines the advantages of ease of making, cheapness, and longer service than other types of screws, and is said to wear out the thread of the wood less than closer wound screws. Tests of these are being conducted on several railroads in the United States.

A discussion is given of the relative value of different tie plates. For use in old ties, or ties which have been in use for some time until the spikes or screws become

loosened, a form of dowel is described which has already shown remarkable results in the way of preventing wear around the spike and preserving the tie for a considerable period beyond the usual time of its usefulness.

The preservative treatment of wood, S. P. Sadtler (*Tech. Quart., 17 (1904), No. 2, pp. 129–144, figs. 3*).—After discussing the objects of wood preservation, notes are given on the structure and chemical composition of various woods, and the more common methods of preservative treatment are described. Attention is called to a radical departure from some of these methods of treatment, and a new method for railroad-tie protection is described at considerable length. This protects not only against fungus attacks, but renders the wood fireproof or fire resistant to a considerable degree.

The method described is said to give to wood a fire-resistant quality, due to the use of aluminum sulphate, without any injury to the structural strength of the wood or the production of any deleterious characters in the product.

The timbers of commerce and their identification, H. Stone (*London: William Rider & Son, Ltd., 1904, pp. XXXVIII+311, pls. 23*).—The author has produced a valuable contribution to the knowledge of commercial timbers and means for distinguishing them. The information given is both scientific and technical, the two being combined in a way to aid in the identification of nearly every kind of timber found in the market.

More than 200 species of wood are described and every genus is figured by excellent photomicrographs which go to make up the plates. After an introduction to the study of woods, the author describes in detail 247 kinds of wood, giving the botany of the species, distribution, sources of commercial supply, physical characteristics, uses, anatomical characters, etc. A bibliography of more than 130 references to literature relating to the subject is given, and a thorough index enables one to readily make use of the text.

No attempt is made to supply keys to the species, as the author thinks the present status of information does not warrant their construction if based upon any systematic classification of the plants.

SEEDS—WEEDS.

The duration of germination experiments, F. Nobbe (*Landw. Vers. Stat., 59 (1904), No. 5–6, pp. 473–480*).—The results of a series of experiments on the germination of seed of Scotch pine, fir, and beet to test the reliability of the rules of the German experiment stations are given. The pine seeds were counted 7, 10, 14, 21, 28, and 42 days from being placed in a germinating chamber, and the fir seeds after 7, 10, 14, 21, and 28 days.

A great variation was noted in the rate of germination of the different lots of seed, but the average germination for the lots of pine seed was 72.7 per cent at the end of 42 days, with 5.8 per cent still fresh and apparently viable. With the fir seed, the average germination was 75.7 per cent in 28 days, with 6.1 per cent still fresh. In experiments with beet seed a variation of 18 per cent was noticed between the germinations determined 5 days and 14 days after beginning.

Effect of bad weather on the vitality of seed oats (*Jour. Bd. Agr. [London], 11 (1904), No. 4, pp. 217–219*).—An account is given of some experiments carried on at the Agricultural Department, Marischal College, Aberdeen, to determine the effect of an abnormal season on the vitality of seed oats. Most of the samples tested were taken either from seed stacks or from granaries, and were selected because they had been exposed in the shock for a longer or shorter time to inclement weather.

Of 34 samples the highest germination was 63 per cent and the lowest 16 per cent, giving an average germination of 34 per cent. Samples of grain that had stood in

the shock from 3 to 6 weeks during rainy, misty weather showed a diminished average germination dependent upon the time the grain was exposed to the weather. The relation between the weight per bushel and the germinating power of a number of samples is shown, from which it appears that in general the germinative ability of seed increases with its weight per bushel.

Twenty-sixth report of the Swiss seed control station at Zurich, F. G. STEBLER ET AL. (*Landw. Jahrb. Schweiz, 18 (1904), No. 2, pp. 45-100, figs. 4*).—A report is given of the operations of the station in testing seeds for the year ended June 30, 1903. During this period 10,274 investigations were made and the maximum, minimum, and average germination of the different kinds of seed are reported. These investigations represented 339,203 kg. of seed. In addition to the germination and purity tests, examinations were made for dodder seed. The relative value of different kinds of clover seed, alfalfa, vetches, and various grasses was also studied. The average purity and germination of all samples of seed tested between 1876 and 1903 are shown in tabular form.

In addition to notes on seed testing, descriptions are given of investigations on certain plant diseases, including a leaf-spot disease of English rye grass caused by *Ovularia lolii* and a leaf-spot disease of white clover due to *Stagonospora trifolii*.

Second annual report of the Central Seed Testing Laboratory of the Aynsome Agricultural Station, Grange-over-Sands, J. S. REMINGTON (*Ann. Rpt. Cent. Seed Testing Lab., Aynsome Agr. Sta., Grange-over-Sands, 2 (1903-4), pp. 50*).—An account is given of the seed-testing operations conducted during the season 1903-4. There were examined during this time 1,077 samples of seeds of all kinds, an increase of about 75 per cent over the amount tested the previous year. A detailed report is given of the results of the different tests, in which the purity, germination, presence of dodder, etc., are shown. In addition to the tabular statements given, the forms of blanks used at the station are shown.

Modern seed testing (*Reprint from Mag. Com., 1903, Oct., pp. 7, figs. 8*).—The importance of good seed and the necessity for scientific and systematic seed testing are shown, and a description given of the Aynsome Seed Testing Station.

Seed testing, J. S. REMINGTON (*Reprint from Roy. Lancashire Agr. Soc. Jour., 1903, pp. 8*).—A description is given of methods of seed testing pursued in the Aynsome Seed Testing Laboratory, and tables given showing the maximum and minimum of purity and germination of different varieties of seed as determined by investigations which have been carried on at the station.

Technical rules for seed testing, J. S. REMINGTON (*Grange-over-Sands, Eng.: Aynsome Agr. Sta., 1903, pp. 8*).—The technical rules for seed testing as practiced at the Central Seed Testing Laboratory of the Aynsome Agricultural Station are given.

Seed testing and seed-testing apparatus, H. WICHMANN (*Mitt. Österr. Vers. Stat. u. Akad. Brauind. Wien, 1904, pp. 7-11; separate from Allg. Ztschr. Bierbrau. u. Malzfabrik., 1904, Mai*).—A report is given of experiments on the germination of barley, in which comparative tests of different forms of germinating apparatus were made.

A report on present methods and standards of seed testing, A. VOIGT (*Separate from Jahresber. Ver. Vertreter Angew. Bot., 1 (1903), pp. 1-11*).—The author discusses methods of seed testing and standards which are followed in some of the countries of Europe.

Selection of seed by chemical methods, WOOD and BERRY (*Proc. Cambridge Phil. Soc., 12 (1903), No. 2; abs. in Bot. Centbl., 95 (1904), No. 19, p. 513*).—Studies are in progress to determine the possible relationship between the chemical composition of beets, ruta-bagas, and mangel-wurzels, and the ability to transmit these characteristics through their seeds.

DISEASES OF PLANTS.

Report of the government mycologist, J. B. Carruthers (*Admr. Rpts., Roy. Bot. Gardens, Ceylon, 1903, Misc., pt. 4, pp. 5–10*).—Considerable attention is given to a disease of tea leaves due to the fungus *Pestalozzia guepini*. This fungus causes a disease known as "gray blight" and occasions at times serious losses to tea plantations. Another serious disease of tea is due to the root fungus *Rosellinia radiciperda*. A third disease which is said to rarely attack tea in Ceylon, though abundant in other districts, is due to the fungus *Marasmius sarmentosus*.

In addition notes are given on the witches' broom of cacao, caused by a species of Exoascus, and rubber canker which are to be discussed in future publications. A brief note is given on the resistance of the spores of *Hemileia vastatrix* to sunlight, so far the spores resisting the direct action of the sun to a very high degree.

Annual report on the diseases and injuries of economic plants, A. A. Yacheoski (*St. Petersburg: Min. Agr. and Imp. Domains, 1904*).—This is the first annual record for 1903 of the Central Phytopathological Station, established by the Imperial Botanical Garden. The present record deals with the diseases of cereals, fodder grasses, garden plants, fruit trees, berries, vines, forest species, orchard and decorative plants, and tropical and subtropical plants.—P. FIREMAN.

Diseases of cereals, D. McAlpine (*Jour. Dept. Agr. Victoria, 2 (1904), No. 8, pp. 709–721, pls. 2, dgm. 1*).—In an address delivered before a convention the author describes a number of diseases of cereals, paying particular attention to rust and take-all. He presents statistics to show the losses attributed to rust in Australia, and reviews the various experiments for its control. The most promising method for the control of rust seems to be in the selection of resistant varieties, and a variety known as Rerraf is said to be able to withstand the rust when other varieties alongside of it were almost entirely destroyed. Other promising rust-resisting varieties are mentioned. For the prevention of take-all the author recommends a series of rotations which does not include wheat or other susceptible plants for a number of years.

Clover rot, W. Freckmann (*Deut. Landw. Presse, 31 (1904), No. 5, pp. 452–454, figs. 6; Bul. Mens. Off. Renseignements Agr., 3 (1904), No. 8, pp. 915–918*).—A description is given of a clover disease caused by *Sclerotinia trifoliorum*, which is said to have been quite prevalent in portions of Europe, causing great injury to clover fields. It becomes conspicuous in September and October, when the leaves present brown spots bordered with yellow, and in about 15 days the entire leaf is affected and finally falls, leaving the plant bare. The development of the fungus is discussed at considerable length. In addition to the ordinary red clover, it has been found to attack crimson, alsike, and white clovers, sainfoin, alfalfa, and other leguminous plants.

Where a field becomes infested with this fungus it is recommended that the cultivation of clover and similar crops be abandoned for a time and the land seeded to grass or given to the cultivation of cereals. If the disease appears to a slight extent in clover fields its effect may be diminished by sowing grass seed, which will gradually replace the clover as it is destroyed and finally result in the production of a meadow.

A disease of endive (*Bul. Mens. Off. Renseignements Agr., 3 (1904), No. 3, pp. 295, 296*).—A brief account is given of a notice published elsewhere of a disease of endive, which has been quite prevalent in parts of Italy. The disease seems to be caused by the fungus *Puccinia prenanthidis*, which causes rusted spots upon the leaves, destroying the plant for use as salad. The progress of the disease is said to be quite rapid, the pustules spreading until the leaf is fully involved and later transformed into a worthless mass.

On account of the use of the plant as a salad, fungicides can not be readily used for its protection. On this account the author recommends careful selection of plants,

the rejection of all which show any traces of disease, and rotation of crops so that endive shall not be cultivated in the same ground for 2 years in succession.

The scab of potatoes (*Bul. Mens. Off. Renseignements Agr., 3 (1904), No. 8, pp. 924, 925*).—A brief account is given of the black scab of potatoes, due to *Œdomyces leproides* or *Chrysophlyctis endobiotica*, the information being largely based upon publications of the Board of Agriculture of England.

The diseases of the potato in relation to its development, L. R. JONES (*Ann. Rpt. New Jersey State Bd. Agr., 31 (1903) pp. 163–175, figs. 8*).—This is a lecture delivered by the author, and is based on investigations carried on at the Vermont Station, all of which have been noted elsewhere.

The biology of Phytophthora infestans, L. MATRUCHOT and M. MOLLIARD (*Ann. Mycol., 1 (1903), pp. 540–543; abs. in Bot. Centbl., 95 (1904), No. 6–7, p. 158*).—Biological studies are given of the potato rot fungus (*Phytophthora infestans*). The fungus was grown on a number of media, including sliced potatoes, cucurbits, etc., and on artificial media of various kinds. The best spore formation was found when grown on natural media, as they are called, growth on an artificial media tending to sterility.

A bacterial rot of onions (*Agr. News [Barbados], 3 (1904), No. 60, p. 245*).—A description is given of the bacterial rot of onions, which was noted in Barbados as affecting the inner scales of the bulb after the crop had been gathered and stored. No fungus was found present, but the diseased scales were swarming with bacteria. While not demonstrated, it is believed that this disease is similar, if not identical, with that previously described by F. C. Stewart, of the New York State Station (E. S. R., 12, p. 55).

Some root-crop diseases in Ireland, T. JOHNSON (*Jour. Dept. Agr. and Tech. Instr. Ireland, 4 (1903), No. 2, pp. 258–263, figs. 8*).—The author describes a disease of mangel-wurzels due to *Œdomyces leproides*, a dry rot caused by *Sphærella betæ*, and a rot of Swedish turnips caused by *Phoma brassicæ*.

Disease of sorghum in the Madras Presidency, C. A. BARBER (*Dept. Land Records and Agr., Madras, Vol. II, Bul. 49, pp. 273–288*).—Descriptions are given of some of the fungus and insect injuries to sorghum, particular attention being given to sorghum smut, 2 forms of which are described as due to *Ustilago reiliana* and *U. tulasnei*. For the prevention of these diseases, the author recommends immersing the seed grain in a copper sulphate or a formalin solution prior to planting. Other diseases due to *Colletotrichum falcatum*, *Puccinia penniseti*, etc., are described.

Experiments for the prevention of black spot or scab of apples, D. MCALPINE (*Jour. Dept. Agr. Victoria, 2 (1904), Nos. 4, pp. 354–360; 8, pp. 761–767, pls. 9*).—A report is given of a series of experiments conducted to test the efficiency of Bordeaux mixture when employed on a commercial scale and also to ascertain the adhesiveness of various fungicides when used for the prevention of the black spot or scab of apples and pears. The first series of experiments was conducted in 1902–3, followed by a second series of experiments in 1903–4.

In the first experiments it was shown that with proper spraying with a well-prepared Bordeaux mixture the disease could be completely controlled. The additions of common salt, sal ammoniac, etc., while slightly increasing the efficiency of the fungicide, are not believed to be necessary. The second season was generally favorable for the development of fungus diseases, and in many instances the attacks were prolonged unusually late in the season. In a large number of orchards a second definite period of infection was observed after the usual primary infection. As in the previous experiments the disease was found to be readily controlled by the use of Bordeaux mixture, and from the results obtained a 6–4–40 formula is preferred.

A precocious decay of Botrytis in Algeria, L. TRABUT (*Bul. Agr. Algérie et Tunisie, 10 (1904), No. 11, pp. 229–232, figs. 2*).—An account is given of an unusual decay of *Botrytis cinerea* on grapes in Algeria in which the flowering clusters, early foliage, young shoots, etc., were badly infested.

The scab or verrucosis of lemons, G. BRIOSI and R. FARNETI (*Atti. Ist. Bot. Univ. Pavia, 2. ser., 10 (1904), p. 60; abs. in Bot. Centbl., 95 (1904), No. 19, p. 515*).—A description is given of a disease of lemons and citrons in Sicily, which is supposed to be the same as the disease known in this country as scab or verrucosis. A study of the fungus has led the authors to describe it as belonging to a new genus, *Rhynchodiplodia citri*.

Mummy oranges and citrons (*Bul. Mens. Off. Renseignements Agr., 3 (1904), No. 6, pp. 691–693*).—A summary is given of an article published in *Agricoltura Moderna*, in which is described a disease of oranges and citrons which results in the drying and hardening of the fruits. The fruits are found to be attacked by fungi, the principal of which is said to be *Botrytis citricola*, n. sp. This fungus is said to be parasitic and is thought will prove of considerable importance to the orange and citron groves of Italy. It is closely related to *B. cinerea*, but differs in some material respects which are described.

For the prevention of the spread of the disease, particularly to fruits that have been gathered, the author recommends the rejection of all which show any rusted spots upon the skin and storage of the fruit in well aerated and dry places only.

The pineapple disease, H. TRYON (*Queensland Agr. Jour., 15 (1904), No. 1, pp. 477–484*).—A discussion is given of a disease of pineapples, the presence of which may be recognized by the modified appearance of the plants. Their ordinary dark-green color gives place to red and yellow, the plants become wilted, the leaves twisted, and later a brownish coloration is quite noticeable. After the disease becomes well established its presence can be observed in the unevenness of the rows, the stunted, discolored plants being quite conspicuous.

The author describes various agencies that have been suggested as the cause of this disease, and from his investigations is led to believe that it is due to the presence of some undetermined fungus which attacks the roots, causing their decay. The presence of the fungus, however, is believed to depend upon a weakened condition of the plants, which is primarily caused by the soil not being in condition for healthy growth.

Investigations on the coffee disease due to Stilbella flavida, F. G. KOHL (*Beihefte Tropenpflanzer, 1903, No. 2, pp. 61–77; abs. in Bot. Centbl., 95 (1904), No. 13, pp. 335, 336*).—Based upon abundant material from coffee plantations in Central America, the author has made a study of the coffee-disease fungus, formerly known as *Stilbum flavidum*. By studying it in pure cultures he has determined the fungus to be a hymenomycete and not in any way connected with *S. vulgare*, a basidiomycetous fungus, which is the type of the genus. On this account he proposes a new name, *Stilbella flavida*, and points out a number of fungi which have been described by various authors and which he claims should be referred to it.

For combating the disease he recommends the collection and destruction of all diseased and fallen leaves, twigs, fruits, etc.; the destruction of all young diseased plants; the stimulation of plants to active growth by the use of proper fertilizers, irrigation, drainage, etc.; the reduction of shade; the pruning of the trees, and finally by the active use of fungicides.

A new cacao disease (*Agr. News [Barbados], 3 (1904), No. 62, p. 281*).—The occurrence of a disease affecting the twigs and leaves of cacao in St. Lucia is reported. The external appearance of the twigs is said to be quite characteristic, the hyphæ of the fungus being joined together into dark-colored threads resembling in a way loose bunches of horse-hair. A similar disease has been reported as occurring on tea in India and Ceylon, which it was found possible to prevent in those countries by careful pruning and the use of a lime-sulphur wash. So far as the author's information goes, this disease has not been previously reported as occurring on cacao in the West Indies.

The leaf cast of Pinus cembra, H. C. SCHELLENBERG (*Schweiz. Ztschr. Forstw.,*

55 (1904), No. 2, pp. 44–48; abs. in Bot. Centbl., 95 (1904), No. 21, pp. 569, 570).—The leaf-cast fungus of the common pine is shown by inoculation experiments to be able to infect *Pinus cembra*. Under natural conditions the disease is transferred to the young needles when growing in moist shaded regions, and especially when the branches are near the ground. This last factor is due, in the author's opinion, to the fact that the fruiting of the fungus takes place on the fallen leaves. By the extensive shedding of its leaves the tree becomes greatly weakened and often killed.

In appearance the disease resembles that of the common pine except that the leaves infected in the spring of the year fall that autumn instead of being carried over until the following spring. The fungus, *Lophodermium pinastri*, is described at some length.

The nutrition of diseased trees with the object of curing them and destroying their parasites, I. J. SHEVIRYEV (*Selsk. Khoz. i Lyesov., 1903; abs. in Zhur. Opuitn. Agron.* [*Jour. Expt. Landw.*], *5 (1904), No. 1, pp. 104–106*).—The author describes the results of 10 years' experiments in elaborating a method for artificially introducing into the living plant foreign bodies in desired quantity, which while not destroying the life of the plant may be of value in protecting it against parasites.

According to the author, the investigations described are based on the following facts: After the spring movement of the sap, when the pressure inside the vessels is greater than that of the atmosphere, there follows in summer and fall a period of negative pressure. If the vessels at this time are brought into communication with the liquid, the latter enters and fills them under the pressure of the outside air. For the successful introduction of liquids into the vessels of the tree it was found necessary to prevent the entrance of air. The author attributes the failure of many experiments in impregnating live trees with solutions to the disregarding of this fact.

In order to exclude the air the vessels are opened under a layer of liquid. For this purpose, if the trees do not exceed 3.5 in. in diameter, their trunks are surrounded by a feeding funnel of aluminum fastened to the tree by means of cement. For larger trees only portions of funnels are fastened to the trunk. After the funnel is fixed in place the solution is poured in and a cut made below the level of the liquid through the thickness of the bark and part of the sapwood. The liquid at once begins to be sucked in and to diffuse above and below the cut. A Mariotte vessel provides for the automatic replenishing of the liquid as it is absorbed.

The absorption of the liquid continues at the initial velocity for some time, after which it slackens, being influenced by climate, season of year, and state of the weather. The absorption takes place most rapidly in dry air at high temperatures and in strong sunlight. The absorption continues for about 5 days, and the immediate cause of its cessation seems to be the choking up of the vessels through which the liquid enters the tree. This is shown by the vigorous renewal of absorption through new cuts made in the tree. In an experiment on an oak tree 7 in. in diameter 11.37 gal. of liquid was absorbed by the tree in 53 hours.

Experiments with a number of solutions colored with eosin or methyl blue showed that liquids diffuse both upward and downward and also horizontally. The diffusion in a horizontal direction seems to be along the rays, as the heartwood does not become colored. The colored liquid has been traced to the smallest branches and also to the leaves, and in the case of experiments with grapevines into the berries themselves. The diffusion into the roots does not seem as uniform as through the sapwood of the trunk.

The author has not made much progress in finding substances which may be introduced in sufficient quantity to be destructive to parasites without being injurious to the plant, but expects interesting results from experiments with certain barium compounds with which he is experimenting.—P. FIREMAN.

A coral-spot disease of various trees and shrubs (*Jour. Bd. Agr.* [*London*], *11 (1904), No. 4, pp. 202, 203, pl. 1*).—A description is given of a disease which attacks

the stems and branches of a large number of fruit and forest trees, as well as various shrubs, being particularly troublesome on sycamore, elm, hazel, apple, pear, and currant bushes. The fungus causing the attack seems to be *Nectria cinnabarina*. The occurrence of the fungus may be noted by the bright coral-colored spots, and wherever observed the diseased branches should be removed and burned.

Report of the government botanist, Madras, C. A. Barber (*Dept. Agr., Madras Presidency, Rpt. 1902–3, pp. 8–10*).—A summary report is given of the investigations carried on by the botanist, particular attention having been devoted to the "spike" disease of sandalwood and the investigation of a serious pepper disease. So far no parasites are recognized as causing the disease of sandalwood, and the disease of pepper can not be definitely attributed to any one cause. Both of these troubles are to be the subject for further investigation.

Canker disease of trees (*Bul. Mens. Off. Renseignements Agr., 3 (1904), No. 8, pp. 921, 922*).—A brief account is given of attacks of *Nectria cinnabarina* on a number of species of trees. The characteristic growth of the fungus is described, and it is suggested that for the prevention of the disease affected branches be cut out and all diseased branches, as well as dead trees and shrubs, be burned. If the disease appears in the nursery, all plants should be removed and burned. Where it occurs on large trees, all wounds made by cutting out the fungus from trunk, branches, or roots should be disinfected and coated with coal tar. As the fungus is able to develop on branches which have been cut from the tree, it is necessary to remove all such from about gardens, nurseries, etc.

A disease of privet (*Oklahoma Sta. Rpt. 1904, pp. 61, 62*).—A brief account is given of a fungus disease of privet which has caused considerable injury to hedges in the vicinity of the station. The fungus attacks the stems, destroying the bark and spreading over and around the stems, more or less girdling them.

When such diseased plants are observed, it is recommended that they be cut out and burned. If the hedge is badly damaged, it is believed best to remove it entirely, as such diseased hedges are a menace to healthy ones in the neighborhood. Spraying with Bordeaux mixture, especially in the spring about the time the buds are expanding, will aid in protecting against attacks of the fungus.

Thirteenth annual report of investigations for plant protection, 1903, P. Sorauer and L. Reh (*Arb. Deut. Landw. Gesell., 1904, No. 94, pp. XXXIII+250*).—Compiled notes are given of investigations by the authors and others regarding various insect and fungus diseases, the material being arranged according to the host plants.

The vegetative life of cereal rusts, J. Eriksson and G. Tischler (*K. Svenska Vetensk. Akad. Handl., 37 (1904), No. 6, pp. 1–19, pls. 3; abs. in Bot. Centbl., 95 (1904), No. 14, pp. 353–355*).—A defense is given of the mycoplasma theory regarding rust propagation (E. S. R., 14, p. 770). The authors describe their methods of investigation and cite *Pseudocommis vitis* and *Dendrophagus globosus* as analogous in some of their methods of growth. The various stages which they claim the mycoplasma passes through until it develops in form for spreading the rust are described.

Experiments with heterœcious rust fungi, W. Tranzschel (*Centbl. Bakt. u. Par., 2. Abt., 11 (1904), No. 3, p. 106; abs. in Bot. Centbl., 95 (1904), No. 9, p. 215*).—The author shows by means of experiments the association of *Æcidium leucospermum* with *Ochropsora sorbi*, of *Puccinia polygoni amphibii* with *Æ. sanguinolentum*, and *Æ. trientalis* with a Puccinia on *Carex limosa*, and also *Æ. coruscans* with the witch-broom fungus Chrysomyxa on *Ledum palustre*.

A contribution to the life history of Ustilago violacea, R. Baar (*Sitzber. Deut. Naturw. Med. Ver. Böhmen, n. ser., 23 (1903), pp. 276–282, figs. 6*).—The results of studies on *Ustilago violacea* or *U. antherarum*, as it is sometimes called, are given. This fungus is known to attack the anthers of many species of Dianthus, Silene, and

related genera, causing the destruction of the pollen. The mycelium which invades the anthers changes their contents to a violet-colored mass. The author has traced the mycelium through the various organs of the plant and shows that it is perennial in the rootstock of the host.

A brief review of Special Bulletins 24, 25, and 26, C. D. SMITH (*Michigan Sta. Bul. 216, pp. 7*).—This consists of a review of the following special bulletins of the station: Insect Enemies of Fruits in Michigan, by R. H. Pettit (E. S. R., 15, p. 1089); Fungus Diseases of Fruits in Michigan, by B. O. Longyear (E. S. R., 16, p. 67); and Spraying Calendar, by L. R. Taft (E. S. R., 16, p. 281).

Tieghemella japonica, K. SAITO (*Jour. Col. Sci., Imp. Univ. Tokyo, 19 (1904), Art. 19, pp. 8, pl. 1*).—A description is given of *Tieghemella japonica*, a new species of fungus recently found in a sake cellar in Japan. The morphology and physiology of the fungus, together with its technical characteristics, are described.

Some observations on the appearance of the oat nematode, K. HANSEN (*Tidsskr. Landbr. Planteavl, 11 (1904), pp. 279–302*).—The investigations of the author show that the oat nematode is widely distributed in Denmark and that great losses result from its attack. The reasons which lead the author to doubt the identity of the oat and the beet nematode (*Heterodera schachtii*) are given in the paper, and various remedies recommended for combating both nematodes are considered.

The following preventive treatments are suggested: A system of crop rotation in which oats, or mixtures of small grains containing oats, do not come oftener than every second, and preferably not oftener than every third or fourth year. As barley is also attacked by nematodes that undoubtedly are identical with the oat nematode, the safer plan is to exclude this crop also from the system of rotation, in the same way as oats, where there is danger of an attack of nematodes. Early sowing has been found of advantage in reducing the severity of an attack of nematodes, and the same holds true in regard to manuring, especially with nitrogenous fertilizers, which tend to render the crop more resistant toward the nematodes.—F. W. WOLL.

ENTOMOLOGY.

Insects, L. F. HENNEGUY (*Les insectes. Paris: Masson & Co., 1904, pp. 804, pls. 4, figs. 622*).—The present volume is intended as a general text-book on the subject of entomology and was prepared for the use of French entomologists partly for the reason that text-books on this subject in the French language were inadequate.

The book is essentially the author's class lectures collected by A. Lécaillon and G. Poirault and considerably elaborated for the present purpose. The subjects discussed in the volume include the general characteristics of insects, classification, anatomical peculiarities of the external skeleton, integument, digestive apparatus, circulatory system, respiratory organs, fat bodies, physiological functions of the muscular and nervous systems, reproductive organs, parthenogenesis, and methods of reproduction, embryology, larval development, metamorphosis of insects, and the origin of adult structures from embryonic tissues.

The literature relating to various subjects is briefly reviewed and a bibliography of 62 pages is included in the volume.

Nineteenth report of the State entomologist on injurious and other insects of the State of New York, E. P. FELT (*New York State Mus. Bul. 76, pp. 91–235, pls. 4*).—As in former reports by the State entomologist of New York, a general account is given of insect outbreaks during the year, office work, special investigations, publications, collections of insects, nursery inspection work, voluntary observers, etc. A synopsis is presented of a number of beneficial insects belonging to

the group Ophionini (pp. 97–125). A considerable number of species of these parasites are described with bibliographical reference notes on their habits, life history, and hosts.

Corythuca marmorata is reported as causing considerable damage to chrysanthemums during 1903. The insect is described in its various stages and notes are given on its life history. For controlling the pest clean culture and spraying with whale oil soap are recommended. During the year the author's attention was called to the damage caused by various species of plant lice, plum curculio, codling moth, pear psylla, San José scale, and other insects affecting fruits, garden vegetables, and shade trees. The author reports some success in the introduction of Chinese lady beetles.

In the control of San José scale a number of insecticides were tested. As a result of these experiments it is concluded that a mechanical mixture of crude petroleum containing 20 per cent of the oil is very effective. In early spring whale-oil soap is recommended. Kerosene emulsion was also found to be a valuable remedy. In experiments with lime-sulphur wash, during which 25 lbs. of lime and 20 lbs. of sulphur for each 240 gal. of water were used after boiling 15 minutes, the results were not as satisfactory as was hoped for. An investigation was also made of diseased and dying trees as affected by forest insects with especial reference to the relation between forest fires and injurious insects.

Report of the entomologist, C. French (*Jour. Dept. Agr. Victoria, 2 (1904), No. 9, pp. 854–859*).—During the year under report a number of experiments were carried out in treating various harmful insects such as San José scale, plant lice, etc. Brief notes are given on this work, and also on the inspection of orchards, nurseries, and gardens, the fumigation and treatment of old fruit cases, the inspection of imports and exports of fruit plants and grain, and miscellaneous injurious insects and birds.

Report of the State entomologist for 1903, S. Lampa (*Meddel. K. Landtbr. Styr. [Sweden], 1904, No. 97, pp. 64, figs. 5*).—During the year under report insect injuries were perhaps more extensive than in ordinary years. This is especially true of *Melolontha vulgaris* and *Cheimatobia boreata*. The latter species was exceedingly injurious to birch trees in various parts of Sweden, and notes are given on the habits, life history, and distribution of the pest. A number of remedies were used with considerable success. These included spraying with Paris green, the use of sticky bands, Raupenleim, etc. Good results were obtained from a combination of these methods. Brief notes are also given on *Psylla mali*, *Diloba cæruleocephala*, etc.

Report of the State entomologist, J. B. Smith (*Ann. Rpt. New Jersey State Bd. Agr., 31 (1903), pp. 333–344*).—A copy is presented of the law of New Jersey regarding the introduction and spread of injurious insects. The author discusses the application and effects of this law, and gives a short account of the work of the entomologist during the year.

Report of the State entomologist, W. M. Schöyen (*Aarsber. Offent. Foranstalt. Landbr. Fremme, 1903, pt. 1, pp. 107–140, figs. 27*).—One of the most serious pests investigated during 1903 was *Aphelenchus fragariæ*, which caused great damage to strawberries in various parts of Norway. The attacks of these nematode worms caused abnormal growths in the leaf stalks of strawberries, with destruction of the roots and ultimate death of the plants. Notes are also presented, as in previous reports, on the more important insects observed during the year on cereals, grasses, legumes, potatoes, other garden vegetables, fruits, ornamental shrubs, and forest trees.

Report of the entomologist for the year ending August 31, 1903, C. S. Banks (*Ann. Rpt. Philippine Com., 1903, II, pp. 594–620, pls. 46*).—A brief account is given of the work of the entomologist during the year, with mention of the problems which present themselves for solution. The major portion of the report is occupied with an account of the insects of cacao already noted (E. S. R., 15, p. 1090).

Report of the entomologists, C. H. and H. T. Fernald (*Massachusetts Sta. Rpt. 1903, pp. 105–109*).—During the year under report the climatic conditions were generally unfavorable to the multiplication of insect pests. A few insects, however, were unusually numerous, particularly the apple-tree tent caterpillar, elm-leaf beetle, San José scale, plum curculio, and imported willow borer. *Neurotoma rufipes* was reported as causing great damage to plum trees in the Connecticut River Valley. The gypsy moth no longer occurs in such large colonies as formerly, but the insect is generally distributed, so that it appears to be impossible to exterminate it.

Entomological department, W. R. Shaw (*Oklahoma Sta. Rpt. 1904, pp. 57–61*).—Brief notes on the best methods of combating Hessian fly, garden webworm, and *Pyrausta rantalis*.

The apple-tree tent caterpillar and its life history, N. F. Davis (*Pennsylvania State Dept. Agr. Bul. 120, pp. 15, pls. 28*).—Brief notes are given on the appearance, habits, life history, and distribution of this insect. In 1903 a large percentage of the caterpillars in Pennsylvania, New York, and New Jersey were destroyed by a bacterial or fungus disease. Notes are also given on other natural enemies of the pest. The usual remedies in controlling this insect are recommended.

Report of the habits of the kelep, or Guatemalan cotton-boll-weevil ant, O. F. Cook (*U. S. Dept. Agr., Bureau of Entomology Bul. 49, pp. 15*).—About 4,000 of these ants in 89 colonies were introduced from Guatemala and appeared to endure the journey very successfully.

A detailed account is presented of the habits and biological relations of the ants. Several of the colonies were found with 2, 3, or more queens. The ant appears to be truly predaceous in habits, and no fear is entertained of its becoming a menace to cotton or other cultivated plants. The ant will attack and destroy the adult boll weevil and exhibits habits which make the author hopeful of its successful colonization in Texas. It still remains doubtful, however, "whether the keleps will survive the winter climate of Texas and whether they can be obtained or propagated in sufficient numbers to serve the practical purpose for which they have been introduced." It is urged that cultural methods of control be still maintained.

The Mexican cotton-boll weevil, E. M. Wilcox (*Alabama College Sta. Bul. 129, pp. 91–104, figs. 4*).—A review is presented of the introduction, history, and present distribution of the cotton-boll weevil within the United States. A copy is given of an Alabama law for preventing the importation of seed from cotton affected with the boll weevil. Notes are given on the habits and life history of this pest. While a number of natural enemies have been mentioned as likely to assist in the control of this pest, the author believes that improved methods of cultivation are the only effective means of controlling the boll weevil so as to raise profitable crops.

Insects injurious to the basket willow, F. H. Chittenden (*U. S. Dept. Agr., Bureau of Forestry Bul. 46, pp. 63–80, figs. 17*).—The author presents an account of the habits, life history, natural enemies, and means of combating imported willow curculio, poplar girdler, bronze birch borer, various species of sawflies, leaf beetles, leaf-eating caterpillars, and plant lice injurious to the basket willow and other species of willows. In combating these pests good results are usually had from complete inundation, and willow plantations on ground which can not be inundated suffer more extensively from insect injuries. Leaf-feeding species of insects may be destroyed by spraying with arsenate of lead, Paris green, or by the jarring method.

The codling moth, C. Mayer (*Agr. Jour. Cape Good Hope, 25 (1904), No. 2, pp. 153–157, figs. 7*).—The condition of infestation with this insect pest is briefly noted and directions are given for applying a most effective preventive remedy for controlling it. The remedies recommended are spraying with Paris green, banding the trees, and destroying windfalls. Brief notes are given on the results obtained from the application of these remedies.

Experimental work with the peach aphis, W. W. FROGGATT (*Agr. Gaz. New South Wales, 15 (1904), No. 7, pp. 603–612*).—The occurrence and life history of *Aphis persicæ-niger* are described in some detail. Infested peach trees were sprayed with lime-sulphur-salt wash containing 30 lbs. lime, 20 lbs. sulphur, and 15 lbs. of salt per 60 gal. of water. It is recommended that this wash be applied to peach trees in New South Wales during the month of July. The cold weather of winter apparently has no effect in checking the propagation of this pest. A number of parasitic insects were observed preying upon the peach aphis, and detailed descriptive notes are presented on these species.

The army worm in Australia, W. W. FROGGATT (*Agr. Gaz. New South Wales, 15 (1904), No. 4, pp. 327–331, figs. 2*).—During the season of 1903–4 the long-continued Australian drought was broken by a period of abundant rainfall. Vegetation grew very luxuriantly and the large numbers of army worms which appeared showed that the eggs of this species were capable of resisting excessive drought and unfavorable conditions. The approved methods of controlling this pest are described and recommended.

Report on Tortrix pilleriana, P. MARCHAL (*Bul. Mens. Off. Renseignements Agr , 3 (1904), Feb., pp. 177–196*).—This insect is considered the most serious pest of grapes in France. It develops one generation per year. A detailed account is given of 3 general methods of procedure against the pest. The most effective method consists in spraying the grape vines with water at a boiling temperature. Similar treatment with superheated steam and spraying with various insecticides also proved fairly satisfactory. The moths may be captured by means of lantern traps. The author recommends the application of boiling water to grape vines during the period of hibernation of the pests.

The strawberry weevil, F. SHERMAN, Jr., and R. W. COLLETT (*North Carolina Dept. Agr., Ent. Circ. 12, pp. 8*).—An account is given of the damage inflicted by this pest on the strawberry industry, together with notes on the appearance, life history, and habits of the insect. It was found by an examination of infested strawberry fields that for a period of 2 weeks after the last picking of the season the insect could be found in an adult, pupal, and larval condition. During this time, therefore, it is possible to attack the pest most advantageously. A large number of remedies was tried for this purpose.

During the experiments reported by the authors air-slaked lime, Bordeaux mixture and Paris green, carbolic acid and water, whale-oil soap in water, spirittine, and other insecticides were sprayed upon infested strawberry plants. As a result of these experiments it is believed that little hope can be entertained of any material benefit from spraying. The best results will probably be secured through the planting of varieties with imperfect blossoms, the prompt mowing and burning of fields, the destruction of rubbish along the edges of strawberry fields, and clean culture, together with spraying with Bordeaux mixture and Paris green. The last-named remedy is recommended not on account of its effect upon the weevil, which is very slight, but because it has a beneficial effect in destroying leaf beetles and controlling leaf rust.

How to know butterflies, J. H. COMSTOCK and ANNA B. COMSTOCK (*New York: D. Appleton & Co., 1904, pp. XII+311, pls. 45, figs. 49*).—The authors have noted in their class work in entomological courses that comparatively few persons are acquainted with the names and habits of the common butterflies. This fact is attributed to the lack of suitable aids for beginners in this study.

The present volume, therefore, is prepared for the purpose of furnishing brief descriptions of species of butterflies with the best possible illustrations, and with notes also on the more important facts in the life history of different species. A general account is given of the relation of butterflies to other insects, the structure, metamorphosis, and life history of butterflies. Each species included in the volume

is described in its various stages. An analytical table is given for the identification of species. As a rule, only those species are admitted which belong to the eastern United States.

A preliminary catalogue of the described species of the family Fulgoridæ of North America north of Mexico, O. H. SWEZEY (*Ohio Dept. Agr., Div. Nursery and Orchard Inspection Bul. 3, pp. 48*).—In this catalogue an attempt has been made to include all species of the family which have been reported in literature accessible to the author. Notes are given on the distribution and synonymy of each species.

Results of a biological study of South American white ants, F. SILVESTRI (*Mem. by Rev. Soc. Cient. "Antonio Alzate," 18 (1903), No. 7-8, pp. 353-378*).—The various kinds of individuals observed in colonies of white ants with notes on the nesting habits and other matters relating to the biology of different species of these insects.

The introduction of the fruit-fly parasite, G. COMPERE (*Jour. Dept. Agr. West. Australia, 10 (1904), No. 2, pp. 68-72*).—The author made a trip to Brazil for the purpose of seeking insect parasites of *Ceratitis capitata*. During this journey notes were made on the prevalence and injurious effects of the fruit fly. A species of beetle was obtained belonging to the family Staphylinidæ which attacks the fruit fly and considerable success was had in transmitting these predaceous insects to England. The beetle attacks the fruit flies only in the maggot condition, but appeared to destroy a large percentage of these pests in Brazil.

Notes on Ixodidæ, L. G. NEUMANN (*Arch. Parasit., 8 (1904), No. 3, pp. 444-464, figs. 2*).—The genera of this family are carefully diagnosed and detailed descriptions are given of the various species, together with notes on their habits and life history.

Life history of Lycæna argiades, F. W. FROHAWK (*Entomologist, 37 (1904), No. 497, pp. 245-249*).—A description is given of the egg, various larval stages, and pupa of this butterfly, with other notes on its habits and life history.

When to spray, A. E. STENE (*Rhode Island Sta. Bul. 100, pp. 121-148, pls. 3, figs. 3*).—In this bulletin the author's purpose was to present a general account of the subject of spraying, together with a tabular statement of the periods when spraying is most effective for various insect and fungus diseases, formulas for the preparation of fungicides and insecticides, and specific directions for the control of the San José scale.

A new general insecticide, H. M. LEFROY (*Jour. British Honduras Soc. Agr. and Com., 1 (1903), No. 1, p. 16*).—The author describes an insecticide having the following formula: 10 lbs. whale-oil soap, 5½ pts. crude Barbados oil, 4 oz. Naphthalene. This emulsion is effective against plant lice, mealy bugs, scale insects, ticks, and other pests on domesticated animals.

The method of applying Paris green, W. B. SEABROOK (*Bul. Dept. Agr. Jamaica, 2 (1904), No. 7, pp. 159, 160*).—The author states that Paris green may be applied to cotton in a dry, unmixed form by placing a small quantity of it in a bag composed of material known as American gray sheeting. The bag is attached to a staff and is gently rapped with a stick while in position over the cotton plant. No injury was caused to the cotton by this method of application.

Mosquitoes in Hawaii, D. L. VAN DINE (*Hawaii Sta. Bul. 6, pp. 30, figs. 12*).—Mosquitoes were not known in Hawaii previous to 1826, at which date *Culex pipiens* was introduced. Within recent years two other species, *Stegomyia fasciata* and *S. scutellaris*, have also been introduced. The most abundant species is *Culex pipiens*. Notes are given on the habits, life history, and breeding places of all three species. A number of fish are known to feed upon the larval mosquitoes, goldfish being considered the most important enemy of the mosquitoes. While it is believed that complete extermination of mosquitoes is impossible, it is urged that strong efforts be made to reduce them as far as possible by drainage of pools and the use of kerosene.

Annual report of the bee keepers' association of the Province of Ontario for 1903 (*Toronto: Ontario Dept. Agr., 1904, pp. 64*).—The work and prospects of the association and the outlook for honey production are briefly outlined in the president's address by A. W. Chrysler (pp. 5, 6). B. O. Lott gave an account of the advantages of out-apiaries (pp. 6–8). It was stated that bees could be shipped for considerable distances to obtain the linden and clover in the spring, buckwheat later, and then back home for winter quarters. With good railway facilities or with good wagon roads it is considered an easy matter to move an apiary 50 or 60 miles without any loss.

A report of the honey exchange committee was submitted by H. G. Sibbald (pp. 20, 21). A decision was reached that honey be sold through a reliable wholesale house and that the members be advised as to the probable prices. M. Pettit discussed forced or shaken swarms (pp. 32–35). A general account of the methods of swarming was given, with notes on the effects of these methods upon honey production under different conditions. For the production of comb honey the speaker recommended that bees be allowed to swarm naturally.

J. Fixter gave an account of bee-keeping experiments at the Dominion Farm apiary (pp. 37–39). This paper has been previously abstracted from another source (E. S. R., 16, p. 275). Among the other papers read at the association, mention may be made of the report of the committee to amend the by-laws of the association by B. O. Lott, chemical work in connection with bee keeping by F. T. Shutt, report of the inspector of apiaries by W. McEvoy, and a historical address on bee keeping by C. C. James.

Bee keeping for beginners, W. CHITTY (*London: Kegan Paul, Trench, Trübner & Co., 1903, pp. VIII+87, figs. 37*).—This volume was prepared for use in schools in accordance with the syllabus of the Board of Education. It contains an account of the economic importance of bees, their life history, modern appliances for apiaries, management of bees, preparation of honey for the market, and the control of bee diseases.

Notes on the silk of spiders (*Agr. Prat. Pays Chauds, 4 (1904), No. 19, pp. 119–121, figs. 3*).—Brief notes are given on the quality of silk spun by various species of spiders and on the mechanical conditions of this fiber.

Report of inspectors on raising silkworms in 1903, L. GODINOT ET AL. (*Ann. Soc. Agr., Sci. et Ind. Lyon, 8. ser., 1 (1903), pp. 161–167*).—Brief notes on the condition of sericulture as observed in the Département du Rhône.

Sericulture in Italy and means of extending the industry in our southern regions, E. VERSON (*Bol. Uffic. Min. Agr., Ind. e Com. [Rome], 5 (1904), No. 3–4, pp. 282–291*).—Notes are given on the conditions which prevail in southern Italy with reference to the possibility of encouraging the raising of silkworms. It is suggested that government experts be detailed to give instruction and other assistance in improving this industry.

FOODS—NUTRITION.

Suggestions to importers of food products, H. W. WILEY (*U. S. Dept. Agr., Bureau of Chemistry Circ. 18, pp. 16*).—In order to facilitate the execution of the law regarding the inspection of imported food products, the attention of importers is called to a number of suggestions. In the absence of contrary judicial interpretation a food product will be deemed adulterated—

"(1) If any valuable ingredient naturally present therein has been extracted.

"(2) If a less valuable ingredient has been substituted therefor.

"(3) If it be colored, powdered, or polished, with intent to deceive, or to make the article appear of a better quality than it really is.

"(4) If it be a substitute for or imitation of a genuine article and offered under the name of that article.

"Products will be deemed injurious to health in the absence of contrary judicial determination—

"(1) If any substance, with the exception of the long-used, well-known condimental substances, viz, common salt, spices, sugar (sucrose or saccharose), wood smoke, and vinegar, be added thereto for preserving, coloring, or other purposes, which is injurious to health, either as determined by actual experimental evidence or in the predominating opinion of health officers, hygienists, and physiological chemists.

"(2) If the products be decomposed, filthy, decayed, or in any unfit condition for human consumption.

"Products will be considered by the Department as misbranded in the absence of contrary judicial determination—

"(1) If any false name or property be assigned thereto in the label, directly or by implication.

"(2) If any false statement be contained in the label relating to the place of manufacture or production of the contents of the package, directly or by implication.

"(3) If they are not of the nature, substance, and quality commonly associated with the name under which they are sold or offered for sale.

"Food products will also be excluded from entry into the United States if they are of a character or kind forbidden entry in the country where they are manufactured or from which they are exported."

"Food products will also be excluded from the United States if they are forbidden to be sold or are restricted in sale in the countries in which they are manufactured or from which they are exported.

The official standards, which have been noted from another publication (E. S. R., 15, p. 702), are quoted.

Officials charged with the enforcement of food laws in the United States and Canada, W. D. BIGELOW (*U. S. Dept. Agr., Bureau of Chemistry Circ. 16, pp. 25*).—The United States laws relating to food supply are enforced by the Department of Agriculture and the Treasury Department. Lists are given of the officials who have this in charge, as well as some data regarding the organization of the work. Similar information for the individual States and Territories having pure-food laws and lists of the officials and chemists directly concerned with the carrying out of the provisions of such laws are also given.

Food of Europeans and native laborers in the Tropics, G. REYNAUD (*Compt. Rend. 13. Cong. Internat. Hyg. et Démogr., Bruxelles, 1903; abs. in Rev. Soc. Sci. Hyg. Aliment., 1 (1904), No. 1, pp. 85–88*).—The author studied rations of Annamites, Chinese, Abyssinians, and others. According to his calculations the requirements for maintenance in tropical and subtropical countries are, per kilogram body weight, 1.25 gm. protein, 0.75 gm. fat, 3.55 gm. carbohydrates, 0.50 gm. alcohol, and 30 calories of energy during the hot season. During the colder season the protein and energy requirements are somewhat greater, the alcohol requirements the same, and the carbohydrates somewhat less.

He also gives values for the food requirements when work is performed. In tropical and subtropical countries the values for moderate work suggested per kilogram body weight are 1.50 gm. protein, 0.75 gm. fat, 0.50 gm. alcohol, 4.30 gm. carbohydrates, and 36 calories of energy. For severe work the protein was given as 1.75 gm., the carbohydrates as 4.98 gm., and the energy as 40 calories, the other factors being the same as before. Similar calculations are given for the colder season. It is stated that the rations of the French troops in the Sudan furnished per man 159 gm. protein, 37 gm. fat, and 547 gm. carbohydrates.

The author discusses the subject of foods, beverages, and condiments suited to the Tropics at considerable length. In his opinion, less protein and fat are required than in colder countries, and carbohydrates should be considered as the principal source of energy in the diet.

Practical dietetics with reference to diet in disease, Alida F. Pattee (*New York: Author, 1904, 2. ed., pp. XVI+311, figs. 3*).—The author states that in the preparation of this edition the original material has been thoroughly revised and additions made. The volume contains discussions of food; food values and classification; nourishment in acute diseases; general rules for feeding the sick; liquid, semiliquid, and solid food; diet in disease; diet in infancy, and related topics, the bulk of the volume being made up of receipts for the preparation of foods and drinks.

Food and diet of man in health and disease, A. Gautier (*L'alimentation et les régimes chez l'homme sain et chez les malades. Paris: Masson & Co., 1904, pp. XVI+524, figs. 8*).—This extended handbook and summary is divided into 3 parts. The first discusses such questions as the theories of nutrition, the functions of nutrients, energy value of food, production of work, and the body as a machine. In the second part the author considers at length the characteristics, composition, and nutritive value of meat, milk, eggs, cereals, vegetables, and other foods, condiments, and beverages, as well as the preparation of food and some related topics. The third part is devoted to discussions of diet in relation to disease.

The situation of gluten flour, A. S. Hoyt (*Dietet. and Hyg. Gaz., 20 (1904), No. 7, pp. 402, 403*).—In view of the fact that gluten flour often contains an excessive amount of starch and is not true to name, the author emphasizes the need of some standard as regards protein content, and points out that with 40 per cent protein present there is still sufficient starch for the growth of the yeast plant and the production of satisfactory bread.

The quantity of phosphorus contained in flour, Balland (*Compt. Rend. Acad. Sci. Paris, 136 (1903), No. 5, pp. 332, 333*).—Since incineration of meal and flour results in a partial loss of phosphoric acid, the author estimated the amount of phosphorus present in the original material. The method is not described.

A grain of wheat: Its structure and properties, N. A. Cobb (*Jour. Dept. Agr. West. Australia, 9 (1904), No. 3, pp. 165–170, figs. 3*).—The structure of the wheat kernel, the distribution of the different nutrients, and related topics are spoken of.

Canned fruit, preserves, and jellies, Maria Parloa (*U. S. Dept. Agr., Farmers' Bul. 203, pp. 32, figs. 5*).—The author has summarized available data on the household preparation of canned fruits, preserves, jellies, and similar products, embodying in her discussion the results of her own experiments and an extended study of the subject.

Among the topics treated of are the use of canned and preserved fruits in the home, preparation of preserved fruits for the market, principles of canning and preserving, sterilization, utensils needed for canning and preserving, and the selection of fruit. The directions for making the various sorts of preserves, jams, etc., are clear and concise, and are accompanied by discussions of the general processes involved and the principles on which they depend.

The seeds of Shorea robusta as a famine food, O. Reinherz (*Agr. Ledger, 1904, No. 5 (Veg. Prod. Ser., No. 81), pp. 33–36, map 1*).—Analytical data are reported and discussed. Some data are also given regarding the changes brought about when the seeds are cooked with water containing caustic soda in the proportion of 1 to 1,000.

Analyses of Indian pot herbs of the natural orders Amarantaceæ, Chenopodiaceæ, and Polygonaceæ, D. Hooper (*Agr. Ledger, 1904, No. 6 (Veg. Prod. Ser., No. 84), pp. 61–72*).—Analyses of 28 specimens are reported and data are given regarding their botanical characteristics, distribution, and the extent to which they are used as food. According to the author, the analytical data show that weight for

weight (on the dry matter basis) the cooked vegetable is equally as nutritious, if not more so, than the uncooked vegetable, the albuminoids being very similar in the 2 cases, and the phosphoric acid being only slightly reduced in amount.

"It would seem that the sugar of the soluble carbohydrates and a certain amount of saline matter are removed by the operations of boiling and straining, and the balance of the albuminoids is maintained by the major portion coagulating and remaining behind with the other insoluble constituents."

A preliminary study of the digestibility of connective tissue mucoids in pepsin-hydrochloric acid, E. R. Posner and W. J. Gies (*Amer. Jour. Physiol., 11 (1904), No. 3, pp. 330–350*).—Some of the conclusions drawn from these investigations were in effect as follows:

Connective tissue mucoids are digestible in pepsin-hydrochloric acid. The digestive process is relatively slow and gradual, however, and considerable substance remains insoluble even under the most favorable zymolytic conditions, the amount being in every case at least 10 per cent of the original mucoid. The soluble products are albuminate, primary mucoproteoses, secondary mucoproteoses, and mucopeptones. The general properties of these bodies are identical with those of typical peptic products.

The indigestible matter appears to consist mainly, if not wholly, of resistant compounds of proteid and glucothionic acid. In most cases the mucoproteoses were also found to be glucothionic acid products of varying composition. A glucothionic acid similar to chrondroitin sulphuric acid was separated from both the indigestible matter and the proteoses. The peptones did not contain the glucothionic acid radical. At least 25 per cent of the indigestible matter consisted of combined glucothionic acid.

Connective tissue mucoids are readily digested by trypsin in alkaline solution. Tryptophan, leucin, and tyrosin are produced from them in abundance.

Food analyses, C. F. Juritz (*Rpt. Senior Analyst, Cape Good Hope, 1903, pp. 9–44*).—Data are reported of a number of examinations and analyses of foods, beverages, condiments, drugs, and potable waters. The bulk of the analytical work was carried out under the local pure-food laws.

Dairy and food division, C. B. Witmer (*Pennsylvania State Dept. Agr. Bul. 118, pp. 62*).—This bulletin includes the laws creating the office of dairy and food commissioner in Pennsylvania and a digest of the laws committed to the commissioner's administration.

Aromatics and nervines in alimentation, A. Valenti (*Aromatici e nervini nell' alimentazione. Milan: Ulrico Hoepli, 1904, pp. 354; rev. in British Med. Jour., 1904, No. 2268, p. 1433*).—Under "aromatics" the author discusses salt, vinegar, sugar, pepper, ginger, and other condiments, giving in each case a brief account of the source, method of preparation, character, and physiological effect. Under "nervines," alcohol, coffee, tea, cocoa and similar products, and tobacco are included.

Studies in body temperature. I, Influence of the inversion of the daily routine; the temperature of night workers, F. G. Benedict (*Amer. Jour. Physiol., 11 (1904), No. 2, pp. 145–169, figs. 5*).—Using a very delicate thermometer, described in a previous publication (E. S. R., 13, p. 878), the author studied fluctuations in body temperature when the daily routine was inverted. "No tendency to an inversion of the temperature-curve by inverting the daily routine of life is observed in any of the experiments reported here."

The calcium content of the feces of nursing infants, J. Korjev (*Inaug. Diss., St. Petersburg, 1903; abs. in Russk. Vrach., 1903, p. 1038; Jour. Physiol. et Path. Gén., 6 (1904), No. 3, pp. 541, 542*).—In this study mother's milk and cow's milk were compared.

The importance of examining the feces, J. STRASBURGER (*Berlin. Klinik, 1904, No. 190, pp. 1-20; abs. in British Med. Jour., 1904, No. 2277, Epit., p. 25*).—In a discussion of the importance of examining feces from a clinical standpoint a number of experimental and analytical methods are described.

The effect of diuretics on the urine, with a diet poor in salts, H. D. HASKINS (*Amer. Jour. Physiol., 10 (1904), No. 6, pp. 362, 363*).—The diuretics tested in experiments with a healthy young man did not increase the renal excretion of sodium chlorid even when the water and urea excretion was increased.

ANIMAL PRODUCTION.

Analyses of concentrated commercial feeding stuffs, W. FREAR (*Pennsylvania State Dept. Agr. Bul. 122, pp. 52*).—During the year 1903 the State department of agriculture examined 242 samples of cattle feeds in compliance with the provisions of the State law, including cotton-seed meal and feed, linseed meal, buckwheat middlings; wheat bran, middlings, and feed; rye chops, feed, and gluten meal; barley chops and feed, and malt sprouts; oat feeds; corn milling products, bran, gluten feeds, hominy meal, and other corn products; mixed feeds with named components, proprietary feeds with the components not named, condimental feeds, and similar goods.

In addition to chemical analyses the author states that the samples were all examined with the microscope as a means of judging of the specific nature of mixed feeds and the freedom of various samples from adulterants.

"Briefly reviewed, the year's examination has not shown new types of adulteration; but the practice of adding foreign products to feeds sold as mixtures of named grains and of selling without guaranty feeds made in whole or in part from by-products still appears very general. Respecting the use of commercial feeds, a final word may not be out of place. For horses and cattle not upon the farm, a great variety of feeds may be used. The farmer, on the other hand, is usually able to grow his fibrous and starchy foods more cheaply than he can purchase them. His need is rather an increased supply of protein with which to supplement and balance up his foods of home production. For this purpose the food purchased must be richer, much richer usually, than corn, which has an average content of 10.3 per cent of protein and 5 per cent of fat."

Concentrated feeding stuffs, J. P. STREET, W. P. ALLEN, and V. J. CARBERRY (*New Jersey Stas. Bul. 175, pp. 68*).—In accordance with the provisions of the State feeding-stuff law, analyses are reported of cotton-seed meal, linseed meal, gluten meal and feed, hominy meal, corn bran, and similar products; distillery and brewery by-products including, among others, dried distillers' grains, dried brewers' grains, and malt sprouts; molasses feeds; mixed and proprietary feeds; dried beet pulp; ground meat; poultry feeds; barley feed, wheat bran and middlings; ground wheat, rye, and oats; buckwheat middlings, bran, and feed; oat middlings, corn meal, and ground mixed grains.

According to the authors—

"Of the 150 different brands of feed received, and which should have been guaranteed, 6 failed to meet this requirement.

"Consumers are urged to purchase no unguaranteed material, except mill products like bran, middlings, and corn meal, for which no guarantee is required.

"Of the 275 samples which are guaranteed, 125 are deficient, 92 of these being low in protein.

"Of the 122 samples which did not require a guarantee, 91 were of normal composition, 23 were variable, and 8 were adulterated.

"In buying feeds to supplement his home-grown supply, the dairyman's aim should be to secure digestible and palatable protein on the most economical terms. A very large proportion of the different brands examined do not meet this requirement. The study of the guarantees and the composition of the various feeds . . . is therefore of great value.

"The quality of the manure made depends to a great extent on the kinds of feeds used, and a judicious selection will result in a great improvement in this direction."

The feeding value of the residue obtained in the manufacture of alcohol from maize, C. MONTANARI (*Staz. Sper. Agr. Ital., 36 (1903), No. 8–9, pp. 751–755*).—Analytical data are reported and discussed.

Disembittering lupines with limewater, P. SOLTSIEN (*Chem. Ztg., 28 (1904), No. 76, p. 889*).—A note on the effect of temperature on the results obtained in disembittering lupines with limewater. Better results were obtained with warm than with cold water. The author also speaks of the use of magnesia water for this purpose.

Digestion experiments with sheep, J. B. LINDSEY (*Massachusetts Sta. Rpt. 1903, pp. 63–79*).—Digestion experiments with sheep are reported, each covering 14 days, of which the first 7 were regarded as preliminary. The various feeding stuffs were fed with meadow hay, the digestibility of the special materials being calculated in the usual way. A summary of the work follows:

Coefficients of digestibility of feeding stuffs—Experiments with sheep.

Ration.	Dry matter.	Protein.	Fat.	Nitrogen-free extract.	Crude fiber.	Ash.
	Per cent.	*Per cent.*	*Per cent.*	*Per cent.*	*Per cent.*	*Per cent.*
Hay, largely Kentucky blue grass, average 3 sheep	63.84	62.53	53.74	66.08	66.62	44.73
Apple pomace, average 3 sheep	72.51	....	47.22	84.48	61.57	54.74
Biles distillers' grains, average 3 sheep	73.01	70.59	95.39	70.43	77.24	....
Merchants distillers' grains, average 3 sheep	79.12	71.68	96.51	80.09	88.83	....
Dried brewers' grains, average 3 sheep	61.40	82.33	88.24	55.74	46.83	....
Malt sprouts, 1 sheep	78.01	76.39	60.31	77.78	102.50	....
Soy-bean meal, average 2 sheep	91.39	91.07	93.51	91.17	140.03	43.32
Hominy meal, 1 sheep	90.80	74.03	88.95	94.18	126.55	34.67

Among the conclusions drawn from these tests were the following: "The [apple] pomace contained fully as much digestible matter as silage made from the smaller varieties of corn. Whether, per unit of dry matter, it is as valuable a feed as corn silage is rather uncertain. This point will be ascertained later. . . .

"The fiber [of dried distillers' grains] showed marked variations in digestibility, in common with all feeds of similar character. While it has been generally held that nitrogenous feed stuffs do not affect the normal digestibility of the coarse fodders they supplement, it certainly seems reasonable to conclude that the addition of 200 to 250 gm. of the distillers' grains to the hay ration, giving a nutritive ratio of 1:4, has resulted in increasing the digestibility of the fiber in hay; which accounts, in the majority of cases, for the apparently very high digestion coefficients obtained. Admitting this to be the case, the fact still remains that, while the digestion coefficient for the fiber is rather of an uncertain quantity, it must be regarded as relatively high. . . .

"Attention is called to the fact that the higher the digestion coefficients obtained for the fiber, the higher are those obtained for the extract. This is undoubtedly due to the intimate chemical and physiological relations known to exist between these two fodder groups. . . .

"It is evident, from all trials thus far made, that the protein and fat [of soy-bean meal], comprising from 50 to 60 per cent of the bean, is very fully digested.

Whether the high digestibility of the fiber and extract in the present experiment is due to the variety of the bean, or is a peculiarity of the sheep employed, will be determined by further tests. . . .

"The addition to the hay of even a carbohydrate feed, such as hominy, seemed to have increased the digestibility of the fiber in the hay, judging from the coefficients obtained for the hominy fiber."

The origin of the hippuric acid produced by herbivora, T. PFEIFFER, R. RIECKE, and C. BLOCH (*Mitt. Landw. Inst. K. Univ. Breslau, 2 (1904), No. 4, pp. 695–728*).—From a large number of experiments with sheep general conclusions were drawn, including among others the following: The addition of easily digested carbohydrates to a ration producing a large amount of hippuric acid diminished its production somewhat. Increasing the amount of digestible proteid consumed slightly increased the excretion of hippuric acid. No relation was found between the putrefactive fermentation of proteid and the production of hippuric acid.

Aleuronat and ground beans were concerned in the formation of hippuric acid not alone on account of their high protein content, but because they must contain the mother substance of this acid. Increasing the alkalinity of the urine by giving sodium acetate had no influence upon the excretion of hippuric acid. Clover hay, which is considered as a fair representative of the leguminosæ, contains only a small amount of the hippuric acid mother substance, and that present is in a very indigestible form.

Contrary results were noted with meadow hay. The greater part of the hippuric acid yielding substance in meadow hay is soluble in hot water. Arabinose, selected as a representative of the pentosans, had no effect on the formation of hippuric acid, but coniferin, a representative aromatic constituent, exerted an influence. The crude fiber of the different feeding stuffs contained a part of the hippuric acid producing substance and in this respect marked differences were noted between clover hay and meadow hay. In the case of the former the digestible crude fiber was principally concerned in the hippuric acid formation, while with the latter this was not the case.

Raising dairy calves without milk, J. B. LINDSEY (*Massachusetts Sta. Rpt. 1903, pp. 80–86*).—A homemade mixture of wheat flour, cocoanut meal, nutrium, linseed meal, and blood meal, recommended by Hayward of the Pennsylvania Station (E. S. R., 14, p. 479), was compared with Blatchford's calf meal as a feeding stuff for calves. In general the meals tested were gradually substituted for milk.

Two calves fed the homemade mixture weighed, respectively, 310 and 260 lbs. at the close of the trial, having gained 1.4 and 1.1 lbs. per day. The first of these calves was 6 months old and the other 5½ months old, and they were receiving 3 lbs. and 2 lbs. of the meal daily at the close of the test. Another calf was fed the commercial feeding stuff under much the same conditions. When 4½ months old it weighed 251 lbs. During the last 42 days of the test no feed was eaten except the calf meal, the average daily gain during this period being 1.15 lbs.

The author's principal conclusions were in effect as follows: The commercial calf meal is hardly as satisfactory as the Hayward mixture during the first 3 months of the calf's life, and it will probably prove necessary to feed one-third skim or whole milk and two-thirds meal during this period. Mixed with hot water 1:6 and fed at first with skim milk, it proved quite satisfactory in the present single trial. It is possible that delicate calves would not thrive as well upon the meal as the one in the present trial. The commercial calf meal was in good mechanical condition and can not be considered especially expensive.

A comparative test in feeding calves, H. P. SUTER (*Agr. Gaz. New South Wales, 15 (1904), No. 5, pp. 489–491*).—Four calves, fed a ration of cod-liver oil and skim milk in the proportion of 2 oz. to 3 gal., gained 1.42 lbs. per day at a cost of 2.88 cts. per pound during the 6 weeks covered by the test, as compared with a gain of 0.94 lb. per day at a cost of 4.06 cts. per pound on a ration of copra cake or cocoanut-oil cake soaked in water and boiled with pollard, molasses, and water for half an hour

and then mixed with skim milk, the proportions fed per day being 4 oz. copra cake, 8 oz. pollard, 2 oz. molasses, and 3 gal. skim milk.

The cod-liver oil ration "is easily fed, and entails little labor in its preparation and mixing. The calves relished the food and appeared in better condition at the end of the test." The copra-cake ration "requires more attention to prepare, and the calves did not thrive so well. The evidence is distinctly in favor of the cod-liver oil ration, both in the cost of ration and in the increase in weight, as well as in the time employed in preparing and feeding the ration."

Eggs as a feeding stuff for calves, Rarkin (*Jour. Soc. Agr. Suisse Romande, 44 (1903), No. 10, pp. 252–257*).—A summary of data which, in the author's opinion, indicate that eggs are very valuable for supplementing skim milk in calf feeding. In one of the tests a calf weighing 60 kg. was fed 24 days, on an average, a ration of 14 liters of skim milk with 6 eggs. The average daily gain was 1.55 kg. per day.

Stock feeding experiments (*Oklahoma Sta. Rpt. 1904, pp. 41–46*).—Using lots of 5 steers each, different combinations of cotton seed, Kafir-corn meal, shelled corn, corn meal, alfalfa hay, prairie grass hay, and wheat straw were tested for 140 days. Before the close of the test 2 of the animals in one of the lots were removed on account of sickness or injury. The gains in weight ranged from 1.14 lbs. per head per day on cotton-seed meal and wheat straw to 2.34 lbs. on cotton seed, Kafir-corn meal, alfalfa hay, and wheat straw. In every case the amounts of feed consumed were recorded. When the steers were sold and slaughtered, the dressed weight ranged from 56.7 per cent of the live weight in the case of the lot fed cotton-seed meal, shelled corn, prairie-grass hay, and wheat straw, to 59.2 per cent in the case of the lot fed corn meal and alfalfa hay.

Three pigs followed each lot of steers. All of them made very small gains except those following the lot fed cotton-seed meal, shelled corn, prairie-grass hay, and wheat straw. This lot made fair gains. During the latter part of the test, to insure satisfactory gains, all the pigs were fed a liberal allowance of corn meal in addition to the feed which they could gather. The total increase in weight ranged from 332 lbs. with the lot following the steers fed cotton seed, alfalfa hay, and wheat straw to 531 lbs. with the lot following the steers fed shelled corn mentioned above. Considering both the steers and pigs, the greatest profit, $29.19, was obtained on the ration of cotton seed, Kafir-corn meal, alfalfa hay, and wheat straw.

Feeding and grazing experiments with beef cattle, J. F. Duggar (*Alabama College Sta. Bul. 128, pp. 51–88, figs. 4*).—Various problems connected with the profitable feeding of cattle under local conditions were studied. In a test made with 4 lots of 5 steers each, covering 84 days, cotton seed was compared with cotton-seed meal, and sorghum hay with a mixture of sorghum hay and cowpea hay and with shredded corn stover.

The steers in lot 1, fed cotton-seed meal and corn chop 2:1 with sorghum hay, made an average daily gain of 2.23 lbs. per head, requiring 4.82 lbs. of grain and 6.56 lbs. of coarse fodder per pound of gain. The steers in lot 3, feed cotton seed and corn chop 3:1 with sorghum hay, made an average daily gain of 1.19 lbs. per head and required 8.12 lbs. of grain and 11.09 lbs. of coarse fodder per pound of gain. On a ration of cotton seed and corn chop 3:1 with sorghum hay and cowpea vine hay in equal parts, the steers in lot 2 made an average daily gain of 1.93 lbs. per head, requiring 5.41 lbs. grain and 6.85 lbs. coarse fodder per pound of gain.

On the same grain ration but with shredded corn stover, the average daily gain of the steers in lot 4 was 0.98 lb. per head, the grain required per pound of gain being 9.41 lbs. and the coarse fodder 10.23 lbs. The financial returns are discussed on the basis of high, medium, and low values for the different feeding stuffs. "Whatever the price of feed the ration of mixed cowpea and sorghum hay, cotton seed, and corn chop was the most profitable.

"The profit in feeding beef cattle is made, not by producing new growth at less cost per pound than it sells for, but in the increased value of the original weight, due to fattening. A margin of 1 cent per pound between purchase price and selling price is desirable.

"About 7 lbs. of raw cotton seed was fed in the daily ration without injury to the health of the average steer."

Some data are given regarding the cost of raising cattle under different conditions. Three grade steers, when 2 years old, fed on skim milk, grain, hay, and pasturage, weighed, on an average, 867 lbs., the cost of a pound of gain being 2.12 cts. On rye pasture alone yearling steers gained 1.67 lbs. per head daily. Grade calves on pasture alone gained 0.72 lb. per head daily and yearling steers 1.43 lbs. During the pasturage season of 7 months the average gains in live weight of cattle of different ages on unimproved sandy pasture ranged from 8 per cent with mature cows nursing calves to 51 per cent with sucking calves. The author points out that "on the winter range cattle of all ages became very thin, and, in the opinion of the writer, it would have been highly profitable . . . to have supplied them with hay and other food during the winter."

Rice meal and corn meal, fed with hay and skim milk, were compared with 2 lots of 2 calves each, the experimental period covering 91 days. The average daily gain on the rice-meal ration was 1.6 lbs. per head and on the corn-meal ration 1.9 lbs. Considerable more feed was required per pound of gain with the rice-meal than with the corn-meal ration. In the author's opinion "rice meal proved decidedly inferior to corn meal."

When inferior shredded corn stover was fed to calves 37 per cent was refused. When a shredded corn stover of good quality was fed freely to steers 44 per cent was rejected. The waste when slightly moldy coarse sorghum hay was fed to steers averaged 20 per cent.

Methods of steer feeding, T. I. Mairs and A. K. Risser (*Pennsylvania Sta. Bul. 68, pp. 10*).—Continuing earlier work (E. S. R., 15, p. 894), the relative merits of feeding steers in barns and open sheds were studied with 2 lots of 12 animals each, the experimental conditions being practically the same as before except that the grain ration consisted of corn-and-cob meal and cotton-seed meal 9:1. The feeding records covered 98 days.

The steers fed in the barn made a total gain of 1,017 lbs., requiring 13.81 lbs. of feed per pound of gain, at a cost of 9.87 cts. The steers fed in the shed gained 1,027 lbs., requiring 15.32 lbs. of feed per pound of gain, at a cost of 11.01 cts. During almost the entire period the authors noticed that the steers fed in the barn seemed to have somewhat better appetites than those fed outside. Records were kept of the temperature throughout the test.

"The general result of this experiment is similar to that of the preceding one along the same line, namely, that the steers in the barn ate a little less feed for a pound of gain than those in the open shed. The results, however, differ in this, that whereas in the first experiment the total feed eaten by the steers in the barn was somewhat less than that eaten by those in the shed, in the second experiment the total feed eaten by the steers in the shed was somewhat less than that eaten by those in the barn.

"It would seem that whatever advantage is shown by the barn over the shed as shelter for fattening steers is not due to the higher temperature of the barn, but to some other condition of environment. It is possible that in this case the fact that the shed was not sufficiently bedded, rendering it uncomfortable for the steers, prevented the outdoor lot from making as good gains as they otherwise should have made."

Cuban cattle and pasture grasses, F. C. Giltner (*Breeder's Gaz., 45 (1904), No. 24, pp. 1132–1134, figs. 10*).—Data are given regarding the kind of cattle raised in

Cuba, the methods of handling and slaughtering, and similar topics. As regards Cuban feeding stuffs, the author states that some 30 different varieties of grasses are to be found on the island, but that Parana and Guinea grass are the most important, especially the former.

As regards the importance of meat in the Cuban diet, the author considers it a staple food. "Habana alone slaughters daily 300 head of cattle besides some sheep and hogs. In addition to this, large quantities of dressed, salt, and jerked meats are imported." Very lean meat is preferred.

Little sketches of famous beef cattle, C. S. Plumb (*Columbus, Ohio: Author, 1904, pp. 99*).—The articles included in this volume were originally published in the *Chicago Daily Drovers' Journal* and were written mainly for students of animal husbandry and such readers as are interested in the history of breeds. Twenty-five famous animals are included in the list, 11 of these being Shorthorns, 7 Aberdeen-Angus, 6 Herefords, and 1 Galloway.

These sketches, Professor Plumb states, "were not intended to be extended studies of individuals and their varying relations to the breeds, but were, rather, life sketches giving the more important reasons why the animals discussed became famous. Each animal may be regarded as a really famous one, with important historical breed connections. There are hundreds of other famous animals distributed through a century of Shorthorn, Hereford, Aberdeen-Angus, and Galloway history. . . . Nevertheless, the 25 sketches . . . are of animals that have played most important parts and are clearly entitled to the prominence here given them." The information has been gathered from a variety of sources, many of which are not readily accessible, and the data can not fail to be of use.

Live stock in Mexico, Biorklund (*Diplomatic and Consular Rpts.* [*Great Britain*], *misc. ser., 1904, No. 614, pp. 41*).—The present conditions of the live stock industry in Mexico are described, as well as the efforts which are being made to develop this industry. According to statistics for the year ended June 30, 1902, the approximate number of horned cattle in Mexico was 5,142,475, goats 4,206,011, sheep 3,424,430, horses 859,247 pigs 616,139, mules 334,435, and donkeys 287,991.

Fattening range lambs, J. W. Wilson and H. G. Skinner (*South Dakota Sta. Bul. 86, pp. 16, fig. 1*).—A test covering 111 days was made with 10 lots containing 10 lambs each at the beginning of the trial, to study the relative value of macaroni wheat, spelt, millet (Black veronesh), and some more common grains. In every case 0.5 lb. of grain was fed per head daily at first, the amount being increased as the test progressed. Lot 1 was fed wheat, lot 2 macaroni wheat, lot 3 oats, lot 4 barley, lot 5 spelt, lot 6 millet, lot 7 corn, lot 8 corn and spelt, lot 9 barley and spelt, and lot 10 macaroni wheat and spelt. Prairie grass hay and *Bromus inermis* hay were fed in addition to the grain.

The average daily gain per head ranged from 0.21 lb. on macaroni wheat and spelt to 0.28 lb. on the wheat, the macaroni wheat, and the millet rations. The cost of a pound of gain ranged from 5.2 cts. on corn to 8.2 cts. on macaroni wheat and spelt. Three weeks before the close of the test the sheep were sheared, and the effect of shearing on the results obtained is discussed. The amount of wool ranged from 46.75 lbs. with the lot fed corn to 59.5 lbs. with the lot fed spelt.

As regards the millet, a trial test made with 5 head of sheep had shown that a large proportion of the unground seed was excreted undigested and that the animals did not thrive as they should, consequently, the millet in the feeding experiment reported was coarsely ground. The authors note that during the entire feeding period the lot of lambs receiving this grain were as thrifty and consumed their feed with as much relish and made quite as uniform gains as any other lot.

Among the authors' conclusions are the following:

"The record of the lot fed on spelt in this test confirms the results obtained by

feeding this grain in former experiments that it requires from 1 to 2 lbs. more to produce a pound of gain than with the other grains.

"[The result obtained] indicates that spelt has a greater feeding value for lambs when mixed with other grains than when fed alone.

"Macaroni wheat as a feed for sheep is equal, pound for pound, to bread wheat and can be fed profitably at the prices quoted in this experiment.

"This test indicates that the Black veronesh (*Panicum miliaceum*) variety of millet seed, when ground coarsely, is excellent feed for lambs; and, on account of the advantages for its growth in this State over other commonly grown cereals, it is a very valuable addition to our list of grains for the production of mutton. . . .

"The increase in gain per head daily made after shearing confirms the results of former experiments, as it was larger but not so marked as with the experiment one year ago."

Pig management, G. M. Rommel (*U. S. Dept. Agr., Farmers' Bul. 205, pp. 40, fig. 22*).—In his summary of available data regarding pig management, the author discusses houses, enclosures, fences, and related subjects, the selection of sows and boars, the feeding and management of sows, pigs, boars, and breeding stock, weaning of pigs, and similar topics, as well as the prevention and treatment of disease and the prevention and destruction of vermin.

Franches-Montagnes horses, S. Bieler (*Chron. Agr. Canton Vaud, 17 (1904), No. 12, pp. 366–369, fig. 1*).—A descriptive article.

Poultry experiments, W. P. Brooks and F. R. Church (*Massachusetts Sta. Rpt. 1903, pp. 150–153*).—The relative merits of wheat and corn supplemented by animal meal for egg production were studied from December 14 to September 4, the nutritive ratio of the 2 rations being 1:4.34 and 1:6.24. Considering the test as a whole, the authors state that the 2 rations were practically equal in value. During the winter period, December 14 to April 1, the egg production on the corn ration averaged about 30 and on the wheat ration 28 eggs per 100 hens per day. During the summer period, April 1 to September 4, the relative egg production on the 2 rations was 43.7 and 44.4 eggs. "The average food cost per egg produced was, on the wheat ration, a very slight fraction over 1 cent; on the corn ration it was 0.85 of a cent."

Egg production on wheat and corn was also studied, skim milk being used as a source of animal food in both cases with corn oil added as a source of fat. For the entire period, which was the same as in the first test, the average egg production on the wheat ration was 35.7 eggs and on the corn ration 41.66 eggs per 100 hens per day, which the authors consider good "for fowls kept in close confinement, especially in view of the fact that the pullets used in the experiment were rather late hatched, and laid but few eggs until the first of February." The average cost of food per egg produced was 1 cent on the wheat ration and 0.8 cent on the corn ration.

When wheat was compared with rice, skim milk being used as a source of animal food in both cases, the results were "decidedly in favor of the ration including rice." For the entire period the average egg production was 0.37 egg per hen per day on rice and 0.33 egg per hen per day on wheat, the cost of feed per egg produced in the 2 cases being 2.1 cts. and 1.2 cts.

The results obtained, the authors note, are in some respects in accord with those of previous years (E. S. R., 15, p. 177). Among the conclusions drawn were the following:

"As the result of experiments in previous years, corn had been found superior to wheat rations when animal meal was used as the source of animal food, while with scraps the two rations gave nearly equal numbers of eggs. In previous experiments, with milk albumin as the source of animal food, the egg production has usually been unsatisfactory when wheat has been the principal grain. . . . This year, with the addition of fat, more eggs have been produced. . . . On the other hand, the ration lowest in fat of all, viz, that including rice, has given many more eggs than the ration including wheat, which furnishes a far greater quantity of fat.

"A study of the rations of this year shows an apparent relation between the quantity of fiber in the food and the egg production. The rations furnishing exceptionally large amounts of fiber, derived principally from such grains as oats and barley, have given very inferior yields of eggs.

"In conclusion, we are justified in saying that our experiments do not lend support to the belief that the nutritive ratios of rations fed to hens must necessarily be narrow to produce a satisfactory product. We have obtained more eggs in winter in all experiments this year on the combinations of foods with the wider nutritive ratios, and in two out of three experiments the result was the same for the summer period. . . . It is well understood that animal matter of some kind is essential to good egg production. Our earlier experiments have shown the great superiority of animal to vegetable protein in rations for laying hens. It is believed, however, that suitable animal feeds, under which class may be included all such as are well preserved and sweet and palatable, may be wisely used in connection with a large proportion of our cheapest grain—corn."

Second annual international egg-laying competition, D. S. THOMPSON (*Agr. Gaz. New South Wales, 15 (1904), No. 5, pp. 476–488, figs. 12*).—Data are given regarding the conditions of the egg-laying contest at the Hawkesbury Agricultural College, the rations fed, and the prize winning pens. Maize is regarded as an important feed for poultry.

"Overfeeding with maize is certainly fattening, and is injurious to good results from laying hens, but this competition has demonstrated that maize carefully fed and only in proportion with natural grass feeding, pollard and bran, mash and meat, has no injurious effects, but, on the contrary, gives higher results in egg production."

Considering the test as a whole, the average number of eggs obtained per hen from the 70 pens, in the year covered by the trial, was 163.25, the average value of the eggs per hen $4.27, and the cost of feed per hen $1.395.

DAIRY FARMING—DAIRYING.

Hay substitutes, D. O. NOURSE (*Virginia Sta. Bul. 148, pp. 83–90*).—A shortage of forage crops caused by drought led to tests with dairy cows and beef cattle of various coarse fodders, including straw mixed with silage, corn stover, wet and dry; straw, wet and dry, and cotton-seed hulls, wet and dry. Fairly good results were obtained. Quotations from the author's summary follow:

"Corn stover can be used to excellent advantage as a roughage for beef animals, and with a moderate amount of grain it compares very well with others given hay. For dairy cows, and when used with silage and a moderate grain ration, it makes an admirable food. We have given a herd of dairy cows no roughage for the entire winter, except stover and silage with grain as mentioned. The animals gave every appearance of thrift, and a good flow of milk continued. . . .

"The use of straw can not be so highly commended, and yet it can serve a good purpose, especially when hay is high in price. If given more grain to make up for the deficit in quality of the straw it will carry stock safely through a winter, and even horses may do hard work if given the best of care. Of course if one can get oat straw it is considerably better than that from wheat. For dairy cows, or in fact for stockers to be carried over, if they can have some silage and the straw mixed with it, as mentioned before, they are likely to come out in the spring in a very thrifty condition.

"Of the cotton-seed hulls we can not speak very encouragingly for this section. As one authority states, 'they are in value about equal to oat straw.' From our trial we should so consider them, though we were obliged to tempt the animals by every known means before they would eat them, due very likely to the fact they had never had access to them before. . . .

"In seasons such as the one just passed, when the rainfall is so small in the early spring as to seriously cut off the hay crop, we often look about for some plant to sow to supplement the small hay harvest. Millets are often sown and with excellent results, but corn may be planted later than is usually considered wise, and yet get a valuable crop."

In a test at the station Pride of the North and Leaming corn, planted July 3, yielded, respectively, 4,220 and 3,860 lbs. per acre.

"Considering the late date of planting, the crop was a good one, and makes a very satisfactory 'hay substitute,' and while costing far less per ton than the cotton-seed hulls, was worth much more to us."

Records of individual cows on dairy farms, A. J. GLOVER (*Illinois Sta. Circ. 77, pp. 31, figs. 20*).—This gives the results of tests of 10 dairy herds during the period of one year, and is in continuation of similar work published in a previous bulletin (E. S. R., 15, p. 292). There were 247 cows in the herds at the beginning of the year, and complete records were obtained of 189. Data are given on the care and production of each herd, along with suggestions for the improvement of conditions.

The best individual record was 8,230 lbs. of milk and 483 lbs. of butter; and the poorest, 1,866 lbs. of milk and 90 lbs. of butter. The best herd record was 5,642 lbs. of milk and 308 lbs. of butter; and the poorest, 3,397 lbs. of milk and 153 lbs. of butter. The average production of all the herds was 5,025 lbs. of milk, testing 3.98 per cent of fat, and equivalent to 233 lbs. of butter.

Effect of feed on the composition of milk and butter fat, and on the consistency or body of butter, J. B. LINDSEY (*Massachusetts Sta. Rpt. 1903, pp. 45–62*).—This has been noted from another source (E. S. R., 15, p. 1110).

Milk and its products in pharmacy and in occult science of early times, K. TEICHERT (*Milch Ztg., 33 (1904), No. 32, pp. 499, 500*).—A contribution to the medical superstition of past centuries.—F. W. WOLL.

Trials of a hand-milking machine, HITTCHER (*Milch Ztg., 33 (1904), No. 24–25, pp. 369–371, 389–391*).—The machine tried is of German origin, invented by Andersen-Schmidt (German patent, No. 118,825). A description of the machine is given in the paper, and the author's experience with the same in the dairy herd of Kleinhof-Tapiau. This was on the whole favorable, but the author considers the machine, like the Thistle milking machine, a makeshift which in no way can take the place of a good milker.—F. W. WOLL.

Trial of the Andersen-Schmidt hand-milking machine, H. WEIGMANN (*Milch Ztg., 33 (1904), No. 29, pp. 449–451*).—The author gives a description of the machine (accompanied by 2 illustrations) and of the trials conducted with the same on a Schleswig-Holstein dairy farm.

The cows gave less milk at the start by the machine than by hand milking, but as they became accustomed to the former the difference apparently disappeared. In a trial with 4 cows the average results obtained by machine and by hand milking during three 4-day periods were as follows: Periods I and III (machine), milk 30.3 and 29.3 liters, fat 1.15 and 1.09 kg.; Period II (hand milking), milk 30.3 liters and 1.18 kg. of fat. A second trial conducted with 4 cows in 5 periods of 4 days each, during which machine and hand milking were alternated, gave the following results:

Comparison of hand and machine milking.

Period.	Method of milking.	Yield of milk.	Fat content.	Yield of fat per day.
		Liters.	*Per cent.*	*Kilograms.*
I	Machine	20.5	3.94	0.807
II	Hand	21.4	4.13	.893
III	Machine	20.5	3.93	.806
IV	Hand	20.3	4.13	.837
V	Machine	18.8	3.92	.741

In the author's opinion, it may be safely assumed that the production of milk and butter fat is not at all, or at least not appreciably, affected by machine milking, when the cows have once become accustomed to being milked by the machine.

The machine will be further tried on several other Schleswig-Holstein dairy farms, in order to determine its practicability under ordinary farm conditions, in how far it can be used by common farm laborers, and to what extent previously hand-milked cows can adapt themselves to machine milking.—F. W. WOLL.

New experiences with the Thistle milking machine, CASPAUL (*Milch Ztg., 33 (1904), No. 39, pp. 611–613*).—A general discussion of the various pros and cons of milking machines, based upon a 4-years' experience with the Thistle on a German dairy farm, where fresh milking cows are purchased and sold for beef after ¾ to 1½ years, when they no longer give milk. Under these conditions, at least, the author considers the machine a success.—F. W. WOLL.

A trial of the Hegelund method of milking in Holland, K. H. M. VAN DER ZANDE (*Milch Ztg., 33 (1904), No. 32, pp. 502, 503*).—The following average results were obtained in a trial with 12 cows separated into two groups:

Comparison of Hegelund and ordinary methods of milking.

[Average yields per day for 6 cows.]

Period.	Group I.			Group II.			Difference between groups I and II.	
	Method of milking.	Yield of milk.	Yield of fat.	Method of milking.	Yield of milk.	Yield of fat.	Yield of milk.	Yield of fat.
		Kg.	*Kg.*		*Kg.*	*Kg.*	*Kg.*	*Kg.*
I	Ordinary, 5 days	144.4	4.396	Ordinary	125.2	3.724	19.2	0.672
II	Hegelund, 1 week	138.4	4.091	Ordinary	123.9	3.540	14.5	.551
III	Hegelund, 10 days	131.8	3.960	Ordinary	116.6	3.384	15.2	.576
IV	Ordinary, 13 days	125.2	3.571	Ordinary	106.8	3.021	18.4	.550

While no appreciable differences in the production of milk or butter fat were obtained in the trial, the author attaches considerable significance to the indirect influence of the Hegelund method and to Hegelund's work in emphasizing the importance of the process to milking.—F. W. WOLL.

Observations in regard to the Bergedorfer regenerative milk pasteurizer, P. VIETH (*Milch Ztg., 33 (1904), No. 37, pp. 579–582*).—Results of a 7-months' test in the Hameln creamery are presented and discussed.—F. W. WOLL.

On the value of the minute fat globules of milk for butter making, KLEIN (*Milch Ztg., 33 (1904), No. 18, pp. 276–279*).—The author conducted a number of churning experiments with normal cream obtained by poor centrifugal skimming, and with mixtures of such cream and that obtained by running rich skim milk through the separator a second time. The fat content of the cream churned on comparative experiments was always brought to a similar percentage by admixture with skim milk.

The results show that the percentage churnability was the same in all comparative trials, and that, therefore, fat globules of minute size which remain in the skim milk, except by the closest skimming, also contribute to the yield of butter. The time of churning was found to be influenced only to a slight extent by the closeness of the skimming.—F. W. WOLL.

Bacteriological-chemical studies of butter in the Province of Posen, K. TEICHERT (*Inaug. Diss., Univ. Lausanne, 1904*).

Skimming experiments with a balance centrifuge, model 1904, H. HÖFT and KURR (*Milch Ztg., 33 (1904), No. 36, pp. 563–566*).—An illustrated description of this centrifuge, of the manufacture of Hollersleben Carlshütte in Flensburg, with results of experiments with the same.—F. W. WOLL.

The production of butter and the butter control in the Netherlands (*Rpts. and Mem.* [*Netherlands*] *Agr. Dept., 1904, No. 1, pp. 45, chart 1*).—This is a descriptive, historical, and statistical report on butter production in the Netherlands, with a description of the cooperative system, dairy associations, and the operations of the butter control stations.

Report of the chemist: Division of foods and feeding, J. B. LINDSEY (*Massachusetts Sta. Rpt. 1903, pp. 37–44*).—This part of the report is an outline of the work done during the year. Statements are made concerning the extent and character of the chemical work done, the results of the inspection of feeding stuffs, the execution of the dairy law, and the testing of dairy herds.

VETERINARY SCIENCE AND PRACTICE.

Report of the State veterinarian, D. F. LUCKY (*Ann. Rpt. Missouri State Bd. Agr., 36* (*1903*), *pp. 33–48, 351–367*).—During the year under report the author's attention was chiefly occupied in the study of outbreaks of Texas fever, glanders, sheep scab, cattle mange, hog cholera, malignant catarrh, rabies, and tuberculosis. A detailed list of the visits made by the State veterinarian in fulfilling his duties is also presented. It is recommended that more of the control work be left in the hands of deputy veterinarians in order that the traveling expenses may be reduced. The desirability of publishing bulletins containing popular information on animal diseases is also suggested.

Veterinary department, L. L. LEWIS (*Oklahoma Sta. Rpt. 1904, pp. 46–52*).—The author discusses vaccination for black leg, the treatment of cattle mange, lumpy jaw, and hog cholera. As a dip for the cure of cattle mange the author recommends zenoleum, or chloro-naphtholeum in 1½ to 2 per cent solution.

Report of the bacteriological station of the Kharkov Veterinary Institute for 1902 (*Kharkov, 1903; rev. in Zhur. Opuitn. Agron.* [*Jour. Expt. Landw.*], *5* (*1904*), *pt. 1, p. 141*).—The report contains an account of the results obtained by the use of anthrax vaccine in controlling this disease among sheep, horses, and cattle. During this work the double vaccine was used, the interval between vaccination being 13 days. The losses from vaccination did not exceed 1 per cent for sheep and 0.25 per cent for horses and cattle. Immunity against anthrax appeared to exist for a period of 2 years.—P. FIREMAN.

Second annual report of the superintendent of government laboratories, P. C. FREER (*Ann. Rpt. Philippine Com., 1903, II, pp. 342–387, pls. 13*).—The author outlines briefly the growth of the laboratory, the preparation of serum, and gives an account of the buildings and equipment. Mention is also made of the biological and entomological work in these laboratories.

A special report on the work of the serum laboratory is presented by J. W. Jobling. In this laboratory a great amount of work has been done in the preparation of rinderpest serum and a study of the pathological anatomy of this disease, methods of transmission, symptoms, and preventive measures. Various methods of immunization were tested including the use of a mixture of glycerin and bile from affected animals, the serum method, and the defibrinated blood method.

Report of the director of the biological laboratory, R. P. STRONG (*Ann. Rpt. Philippine Com., 1903, II, pp. 411–594, pls. 29, figs. 64*).—Considerable work was done in this laboratory in a study of amebic dysentery and in making blood tests and doing other routine work for physicians. A special report on trypanosoma, with reference to surra in the Philippine Islands, is presented by W. E. Musgrave and M. T. Clegg. This part of the report has already been noted from another source (E. S. R., 15, pp. 1131 and 1132).

A report on hemorrhagic septicemia in animals in the Philippine Islands is presented by P. G. Woolley and J. W. Jobling. This disease is said to have caused very heavy losses and was felt most severely in regions which had already been devastated by rinderpest. Detailed notes are given on a considerable number of cases and experiments are reported during which laboratory animals were inoculated and studied for the purpose of determining the course and symptoms of the disease. It is recommended that all affected animals be prevented from gaining access to running water which might carry contagion to other animals, although it is by no means certain that hemorrhagic septicemia is contagious.

The results of physiological investigations, L. Asher and K. Spiro (*Ergebnisse Physiol., 3 (1904), pp. 636, pls. 5*).—This section of the report on physiological studies is devoted to biochemistry, including the subject of blood elements and chemical bodies found in the serum and blood corpuscles, the chemistry of spermatozoa, intestinal fermentation, general cellular chemistry, activity of the salivary glands, fermentive cleavage of fat, the influence of active pharmacological principles on metabolism, nitrogen metabolism in plants, the physiology of pentoses, formation of carbohydrates from protein, and a review of experiments on metabolism and energy in the human body. This last review was prepared by W. O. Atwater.

Animal sanitation, E. Van Godtsenhoven (*Bul. Cercle Études Agron. [Brussels], 1903, No. 8, pp. 363–368*).—Attention is called to the importance of securing proper food, ventilation, temperature, and exercise for domesticated animals so as to prevent so far as possible the development of tuberculosis and other diseases.

Protozoan diseases, F. J. Bosc (*Centbl. Bakt. u. Par., 1. Abt., Orig., 36 (1904), No. 4, pp. 487–493*).—Diseases due to protozoa are called bryocytic on account of the fact that as indicated by this term the diseases in question are characterized by a proliferation of cells. According to the author's classification the diseases included in this group are smallpox, sheep pox, foot-and-mouth disease, rabies, etc. The essential pathological lesions of these diseases are described.

The bactericidal power of the blood, O. Bail (*Sitzber. Deut. Naturw. Med. Ver. Böhmen, n. ser., 23 (1903), pp. 96–100*).—Attention is called to the importance of understanding as thoroughly as possible the various bodies found in the blood. This work is regarded as necessary in the scientific study of the problem of immunity. The well-known fact of the bactericidal power of the blood of immunized animals has usually been attributed to the formation of special bodies in the blood under the influence of the pathogenic bacteria or to the increased destructive action of certain leucocytes. These matters require further study.

Actinobacillosis, C. H. Higgins (*Canada Dept. Agr., Biol. Lab. Bul. 1, pp. 8, pls. 8*).—This disease was studied on 4 cases in Canada and was found to be identical with the disease described by Lignières and Spitz in Argentina, but not so virulent. Detailed clinical notes are given on the 4 cases which came under the author's observation.

The gross lesions are very similar to those of actinomycosis. The pus, however, is characteristic, of a semi-solid consistency, almost transparent and containing white granules barely visible to the naked eye. The pathogenic organism of the disease closely resembles that of fowl cholera. Guinea pigs inoculated intraperitoneally died in from 19 to 21 days. Similar lesions are produced by artificial inoculation of rabbits. The author has conducted no experiments with remedies, but recommends large doses of potassium iodid.

The action of bacteria on toxins coming from other species of bacteria, Garnier and G. Sabaréanu (*Arch. Méd. Expér. et Anat. Path., Paris, 1. ser., 16 (1904), No. 5, pp. 557–570*).—The authors' experiments were confined to the diphtheria and anthrax bacilli and to toxins of tetanus and diphtheria. It was found during a study of these bacteria and toxins, especially by means of inoculation experiments with

guinea pigs, that the resistance of the diphtheria toxin was rather different toward the diphtheria bacillus and bacillus of anthrax. A long series of experiments were made to determine the effect of these bacilli upon the toxin of tetanus.

As a general result of the experiments reported in this paper, it is concluded that the action of bacteria upon toxins is variable and depends upon the organisms and toxins concerned. The diphtheria bacillus destroys the diphtheria toxin, but increases the virulence of the tetanus toxin. On the other hand, anthrax bacillus destroys tetanus toxin but intensifies the toxin of diphtheria. Apparently the destruction of the tetanus toxin by the anthrax bacillus is due to the direct action of the bacillus upon the toxin. Old tetanus toxin attenuated by simple contact with the air and light, and especially toxin which has been subjected to the action of the anthrax bacillus, still retains a certain toxic property, although the power of producing tetanus has been lost.

Annual report on progress in the study of pathogenic micro-organisms, P. VON BAUMGARTEN and F. TANGL (*Jahresber. Fortschr. Lehre Path. Mikro-organ., 18 (1902), 1. Abt., pp. 368*).—As usual in these annual reports the present volume contains brief abstracts of text-books, compendiums, and original treatises on the various pathogenic micro-organisms, whether bacteria, fungi, or protozoa. Detailed classified bibliographical lists are presented at the beginning of each section of the volume.

A text-book upon the pathogenic bacteria, J. MCFARLAND (*Philadelphia: W. B. Saunders & Co., 1904, 4. ed., pp. 629, figs. 153*).—This is a revised and enlarged edition of the author's text-book on pathogenic bacteria. The subjects discussed in the volume include the biology of bacteria, infection, immunity, disinfection, cultivation of bacteria, experimentation upon animals, and other general bacteriological topics, together with detailed accounts of the organisms concerned in the production of various diseases of man and animals, including pneumonia, tuberculosis, glanders, actinomycosis, tetanus, rabies, anthrax, chicken cholera, hog cholera, swine plague, malignant edema, black leg, etc.

Bacteriological studies, B. GALLI-VALERIO (*Centbl. Bakt. u. Par., 1. Abt., Orig., 36 (1904), No. 4, pp. 465–471, figs. 6*).—Detailed notes are given on the growth and behavior in various culture media of *Corynebacterium vaccinæ*, *Bacterium diphtheriæ avium*, and *B. candidus*. It was found during a study of roup in fowls that the roup organism was very susceptible to the action of lemon juice and that nearly all infected birds treated by repeated doses of this substance recovered entirely.

Veterinary police ordinance of March 3, 1904 (*Min. Int. [Italy], Ord. Pol. Vet., Mar. 3, 1904, pp. 20, pls. 3*).—A copy is given of an ordinance of the veterinary police under the Minister of the Interior of Italy for the prevention and control of infectious diseases among animals.

Veterinary dictionary, II, P. CAGNY and H. J. GOBERT (*Dictionnaire vétérinaire. Paris: J. B. Baillière & Sons, 1904, vol. 2, pp. 854, pls. 4, figs. 932*).—This constitutes the second volume of the author's veterinary dictionary and completes the work. It includes all material arranged in an alphabetical manner from I to Z.

Directions for meat inspectors, R. OSTERTAG (*Leitfaden für Fleischbeschauer. Berlin: Richard Schoez, 1904, pp. XIV+314, figs. 176*).—The purpose of the present volume is to furnish information for persons without a veterinary training concerning the more common pathological conditions met with in meat inspection, and also concerning the normal appearance of various parts and organs. Chapters are devoted to the legal foundation of meat inspection, the training of meat inspectors, methods of butchering, infectious diseases, animal parasites, preservation and sterilization of meat, etc.

Statistics on German meat inspection, R. EDELMANN (*Deut. Tierärztl. Wchnschr., 12 (1904), No. 41, pp. 405–408*).—Brief notes are given on the methods of preparing the statistics obtained from the inspection of animals and meat in abattoirs, and

attention is called to the valuable results which may be obtained by proper interpretation of these statistics.

Tuberculosis of the retropharyngeal glands in cows, E. LIÉNAUX (*Ann. Méd. Vét., 53 (1904), No. 9–10, pp. 515–519*).—The importance of alterations in these glands as evidence of infection with tuberculosis is briefly noted. Detailed descriptions are also presented of the clinical symptoms of this affection in 2 cases. In the first case, respiration was accelerated and was somewhat interfered with as a result of the swelling of the retropharyngeal glands. The temperature of the animal remained about 39° C. In the second case, an apparent amelioration took place and persisted for 2 months. This, however, should in no case be taken as evidence of recovery from the disease.

Tuberculosis in its relation to the dairying industry, J. R. WEIR (*Jour. Dept. Agr. Victoria, 2 (1904), No. 8, pp. 750–756*).—Notes are given on the history, distribution, cause, symptoms, and treatment of this disease, especially as observed in various parts of Australia.

Bovine tuberculosis, V. A. MOORE (*Rpt. New York State Dept. Agr., 10 (1902), pp. 199–252, pls. 8, figs. 3*).—In this report the author presents a general account of this disease discussing in considerable detail its etiology, distribution, prevalence, symptoms, pathology, and treatment. Notes are given on the use and value of tuberculin tests and recommendations are made regarding the methods of procedure with tuberculous cattle.

Report of the State commission on bovine tuberculosis (*Ann. Rpt. New Jersey State Bd. Agr., 31 (1903), pp. 313–323*).—During the year 2,450 cattle were examined, of which number 473 were found to be tuberculous and were condemned. The average indemnity paid for cows was $24.17. A brief discussion is presented of the causes of infection from tuberculosis, together with notes on general sanitation and methods of preventing the spread of this disease.

Tuberculosis a preventable disease, with especial consideration of the distribution of tubercle bacilli and the usual avenues of infection, J. F. CORBETT (*Trans. Minnesota State Med. Assoc., 36 (1904), pp. 218–229*).—Attention is devoted in this article to the subject of bovine tuberculosis as one of the well-known sources of infection for the disease in man. While it is admitted that a large number of cases of human tuberculosis are of intestinal origin and arise from infection with bovine tubercle bacilli, the importance of pulmonary infection is insisted upon. Brief notes are given on the work of various investigators which show that human and bovine tuberculosis are forms of the same disease.

Pulmonary pseudo-tubercles in cattle due to arteritis, H. ZWAENEPOEL (*Ann. Méd. Vét., 53 (1904), No. 9–10, pp. 522–526, figs. 3*).—As a result of arteritis of various forms multiple thrombi and infarcts may be formed and may become lodged in the blood vessels of the lungs, thus giving rise to tubercles resembling those of true tuberculosis. The author discusses the differential diagnosis between such tubercles and tuberculosis, and describes in detail the nodules which were observed in a case of this sort.

An agglutinating substance in the organism of animals possessed of natural immunity, P. ZABOLOTNOFF (*Ann. Inst. Pasteur, 18 (1904), No. 8, pp. 527–534*).—The literature of this subject is briefly reviewed. The author studied the effect of the normal serum of guinea pigs from the blood of hogs. The technique of the experiments is described in detail. It was found that the serum of guinea pigs contains no specific agglutinin for the bacillus of swine erysipelas. Evidence is presented to show that the protection of hogs against this micro-organism is brought about entirely through the action of the leucocytes.

Glanders in horses, with an account of its transmission to man, PROFÉ (*Fortschr. Vet. Hyg., 2 (1904), No. 6, pp. 167–170*).—In one case of glanders in a horse

the condition of the animal became considerably worse after an intravenous injection of colloidal material. The body temperature rose and the laryngeal glands showed excessive swelling. A subsequent mallein test indicated the presence of glanders, the temperature rising to 40.6° C. The disease was also transmitted to an attendant, in whom it resulted fatally.

Contagious abortion in cattle (*Bd. Agr. and Fisheries* [*London*], *Leaflet 108, pp. 14*).—Simple or sporadic abortion is described for the purpose of distinguishing it from the contagious form of the disease. Brief notes are given on the results obtained by the internal administration of carbolic acid and the external use of various antiseptics in the treatment of this disease.

As a result of these experiments it is recommended that all aborting cows should be isolated and no longer used for breeding purposes. Sheds should be treated with a lime wash every 3 months and the parts of the buildings which can not be reached may be sprayed with some other antiseptic. All cows in the herd should be treated externally with some antiseptic solution. For this purpose the author recommends Izal, 1 part to 80 parts of water.

African coast fever, W. ROBERTSON (*Agr. Jour. Cape Good Hope, 25* (*1904*), *No. 3, pp. 262–268, pl. 1, figs. 15*).—The symptoms, post-mortem occurrence, cause, and means of infection of this disease are briefly described. The disease may be transmitted through the agency of the brown tick and the black-pitted tick, but chiefly by means of the former. The inoculation method devised by R. Koch is said to have proved ineffective in practice. Attention is directed to the importance of proper fencing and dipping for the destruction of ticks. Infested animals may be freed from ticks by dipping in kerosene and various arsenical and other dips.

Distribution of coast fever ticks, C. P. LOUNSBURY (*Agr. Jour. Cape Good Hope, 25* (*1904*), *No. 3, pp. 268–270, pl. 1*).—The distribution of *Rhipicephalus appendiculatus*, *R. simus*, *R. evertsi*, and *R. capensis* is briefly outlined, with an account of the agency of the first 2 species in the distribution of African coast fever.

The sheep fluke, N. A. COBB (*Agr. Gaz. New South Wales, 15* (*1904*), *No. 7, pp. 658–669, fig. 1*).—Attention is called to the agency of birds, especially ducks, in the destruction of snails which may carry the intermediate stage of liver fluke. These birds must, therefore, be considered as of some importance in the control of liver-fluke disease. Occasionally the liver fluke is found in the liver of the kangaroo, hare, rabbit, and wallaby, but nearly always in small numbers.

During the author's investigation of this subject it was found that the extent of infestation by liver flukes may be accurately estimated by a determination of the number of eggs in the excreta. The eggs are distributed in a uniform manner in the excreta of the sheep. It is necessary to carry on further experiments in order to determine the variation in a number of eggs due to age, breed, kind of feed, and length of infestation.

Infectious diarrhea in lambs, D. HUTCHEON (*Agr. Jour. Cape Good Hope, 25* (*1904*), *No. 3 pp. 281–283*).—A study of several outbreaks of this disease in lambs led to the conclusion that the disease is due to a pathogenic organism which gains entrance to the young animal through the navel cord at the time of birth. The disease may most successfully be prevented, therefore, by antiseptic treatment.

Official treatment of swine plague, F. GLAGE and C. NIEBERLE (*Fortschr. Vet. Hyg., 2* (*1904*), *No. 6, pp. 161–167*).—Brief statements are made regarding the regulations of the veterinary police in various parts of Prussia with reference to swine plague. The authors discuss the value of these regulations in controlling the disease. With regard to the carcasses of infected hogs the authors held the opinion that the meat is not injurious to health and need not be considered of inferior value except in cases of great emaciation or jaundice as a result of the disease. Further experiments are required to determine the harmful or harmless character of the milk of infected hogs.

Prevention of swine diseases, A. T. PETERS (*Agriculture [Nebraska], 3 (1904), No. 6, pp. 10, 11*).—As an intestinal and antiseptic vermifuge the author recommends the use of a coal-tar creosote solution in water at the rate of 1:100. A formula is also presented for the preparation of a tonic to be administered in cases of hog cholera.

Vaccination for hog diseases, GRAFFUNDER (*Berlin. Tierärztl. Wchnschr., 1904, No. 41, pp. 673, 674*).—A brief outline is given of the vaccination methods proposed by Ostertag and Schreiber. The former system consists in the use of a polyvalent serum and is based on the assumption that young pigs, after receiving this serum, have the power of developing an active immunity toward the disease whenever they happen to become naturally inoculated with pathogenic bacteria. The use of septicidin on the other hand is combined with artificial inoculation of pure cultures. These methods have been tried on a number of animals, but the author hesitates to draw final conclusions regarding the results. It is believed, however, that the experiments should be continued on a larger number of animals, and it is recommended that the district government undertake to assume the expense of such experiments.

Report of the State board of health, H. MITCHELL (*Ann. Rpt. New Jersey State Bd. Agr., 31 (1903), pp. 327–329*).—A list is presented of the cases of glanders observed in the State during the year, with notes on the disposal of such animals, and a brief account of an outbreak of anthrax during which 172 animals died.

The prevention of anthrax, U. E. FERRETTI (*Gior. R. Soc. ed. Accad. Vet. Ital., 53 (1904), No. 40, pp. 937–942*).—As the result of an extended study of anthrax in the vicinity of Rome the author comes to the conclusion that notification of the existence of this disease should be compulsory, and recommends that more attention be given to disinfection and the destruction of the carcasses of animals dead of the disease. Vaccination of exposed animals in infected localities should also be required.

Fowl diphtheria, H. STREIT (*Ztschr. Hyg. u. Infectionskrank., 46 (1904), No. 3, pp. 407–462, pls. 3*).—The symptoms, etiology, and pathological anatomy of roup are discussed in considerable detail. The roup bacillus is described and mention is made of its behavior on different culture media. The virulence of the roup bacillus was considerably increased by repeated passage through pigeons. It was found to be pathogenic for rabbits, guinea pigs, and mice, as well as for pigeons and fowls. The disease was apparently transmitted more easily by mere association of sick with healthy fowls than by direct inoculation. Immunization and inoculation experiments showed that roup is a disease quite distinct from diphtheria of man.

Epithelioma in pigeons, THÉZÉE (*Bul. Soc. Études Sci. Angers, n. ser., 32 (1903), pp. 71, 72*).—The author notes the occurrence of epithelioma upon the walls of the stomach in pigeons and describes in some detail the pathological anatomy of these structures, calling attention to their similarity to cancer in man.

A new parasite (Strongylus quadriradiatus) found in the pigeon, E. C. STEVENSON (*U. S. Dept. Agr., Bureau of Animal Industry Circ. 47, pp. 6, figs. 10*).—According to the author this is the first species of Strongylus reported as occurring in pigeons. It was present in large numbers in a flock of pigeons, the larger part of which recently died during the outbreak of an unknown disease. The worm is described with detailed anatomical notes on its various features. The greatest injury is apparently caused by the worms burrowing into the mucous layer of the intestines, thus offering a point of entrance for pathogenic bacteria.

Demonstration of specific parasites in rabies, L. LUZZANI (*Centbl. Bakt. u. Par., 1. Abt., Orig., 36 (1904), No. 4, pp. 540–545, pl. 1*).—The author was able to demonstrate the presence of the peculiar organisms described by Negri and believes that these are to be considered as the cause of rabies.

Blood parasites, O. MALM (*Norsk Vet. Tidsskr., 16 (1904), No. 4, pp. 81-92, figs. 4*).—A review is given of blood parasites belonging to the group protozoa, particularly the malarial organism, and its relation to mosquitoes.

Animal parasitology, M. NEVEU-LEMAIRE (*Parasitologie animale. Paris: F. R. de Rudeval, 1904, 2. ed., pp. 220, figs. 301*).—A discussion is presented of the habits, life history, and economic importance of animal organisms which are in any way injurious to man. These parasites belong to 9 natural orders of the animal kingdom particularly to Vermes and Arthropoda. The habits, life history, and injurious effects of each species are briefly noted with reference to methods of combating them.

AGRICULTURAL ENGINEERING.

Preparing land for irrigation and methods of applying water (*U. S. Dept. Agr., Office of Experiment Stations Bul. 145, pp. 84, pls. 7, figs. 33*).—"The purpose of this bulletin is to bring together the results of actual experience in preparing land for irrigation, for the benefit of farmers who are now irrigating or who may in the future undertake the reclamation of lands now arid. The information contained in this report as to the tools and implements used, the methods to be employed, and the cost of the work is based on actual examples and affords a reliable guide to the cost of these features of irrigation in the districts represented, while the number and wide distribution of these districts will make possible approximate estimates of the cost of the different methods and will help greatly in the selection of the one best suited to given conditions."

The general discussion and comparison of methods of preparing land for irrigation described in this bulletin, the descriptions of furrow irrigation, the check system of irrigation, the use of flumes and pipes in furrow irrigation, the basin method of irrigation as practiced in the Santa Clara Valley, California, and irrigation by flooding as practiced in Gallatin Valley, Montana, were prepared by S. Fortier.

The use of metal pipe and canvas hose in the irrigation of field crops in California is described by A. P. Stover; preparing land for irrigation in Salt Lake Basin, by E. R. Morgan and A. P. Stover; the clearing and leveling of land in Imperial Valley, California, by J. E. Roadhouse; irrigation by the furrow system in Washington, by C. G. Elliott; irrigation practice in Nevada, by G. H. True; while methods of preparing land for irrigation in use in western Kansas, in Nebraska, and in Wyoming are described by L. G. C. Mayer, O. V. P. Stout, and William Francis Bartlett.

Professor Fortier and R. P. Teele, editorial assistant in this Office, edited and arranged the report for publication.

Report on drainage investigations, 1903, C. G. ELLIOTT (*U. S. Dept. Agr., Office of Experiment Stations Bul. 147, pp. 62, pls. 5, figs. 12*).—This report covers the first year's work in drainage investigations by this Office. It explains the importance of drainage in the United States and describes plans which have been made and put in operation "for reclaiming alkali lands at Fresno, Cal., in Yakima and Atanum valleys, Washington, and in Grey Bull Valley, Wyoming; plans for the drainage of overflowed bottom lands in the Missouri Valley in Iowa; and experiments with the use of drains to prevent hillside erosion in Georgia."

Sanitary conditions in the home and on the farm, H. METCALF (*South Carolina Sta. Bul. 89, pp. 31, figs. 9*).—This is a popular bulletin on sanitation. The topics discussed are the dangers of dust, school-room sanitation, sewage disposal, disinfectants, water supply, milk, food, and the dangers from insects.

Current wheels: Their use in lifting water for irrigation (*U. S. Dept. Agr., Office of Experiment Stations Bul. 146, pp. 38, pls. 4, figs. 21*).—This bulletin contains a discussion of the theory of current wheels, and descriptions, photographs,

and drawings of a large number of wheels now in use in California, Colorado, Idaho, Utah, and Washington, with notes on their good and bad features.

The importance of the water supply in agriculture, STRECKER (*Fühling's Landw. Ztg., 53 (1904), Nos. 10, pp. 357–360; 11, pp. 398–407*).—A general discussion of the importance of a water supply for power purposes, domestic uses and watering stock, and irrigation.

Machinery at the general agricultural exposition of Paris, M. RINGELMANN (*Jour. Agr. Prat., n. ser., 7 (1904), Nos. 11, pp. 356–359, figs. 6; 12, pp. 388–392, figs. 12; 13, pp. 421–426, figs. 9; 14, pp. 448–452, figs. 9*).—Accounts are given of traction motors, cultivators, seed and fertilizer distributors, weeders, spray machines, harvesting and thrashing machines, mills for grinding, pasteurizers, pumps, centrifuges, hail protection cannon, and miscellaneous implements and machines.

MISCELLANEOUS.

Thirteenth Annual Report of Oklahoma Station, 1904 (*Oklahoma Sta. Rpt. 1904, pp. 15–68*).—This includes a report of the director; a summary of the press bulletins issued during the year, meteorological data noted elsewhere, and a financial statement for the fiscal year ended June 30, 1904.

The press bulletins are to a certain extent a repetition of matter printed in the regular bulletins of the station and deal with a variety of subjects, including the following: Wheat experiments, pasturing wheat, delayed germination of wheat, the oat crop, seed for spring crops, choosing seed corn, comparative yields of Kafir corn and Indian corn, forage rape, Bermuda grass, ponds for stock water, steer-feeding experiments, preventing blackleg, cattle mange or Texas itch, lumpy jaw, hog cholera, plant windbreaks, fruit varieties, planting red cedar seed, Arbor Day, methods of combating the Hessian fly, checks for migrating caterpillars, the webworm on cotton and alfalfa, and a disease of the privet. New matter contained on the above subjects has been noted elsewhere in this issue.

Sixteenth Annual Report of Massachusetts Station, 1903 (*Massachusetts Sta. Rpt. 1903, pp. 175*).—This contains the organization list of the station; a financial statement for the fiscal year ended June 30, 1903; reports of heads of departments; and miscellaneous articles abstracted elsewhere.

Australia as a food-producing country, C. C. LANCE (*Jour. Dept. Agr. West. Australia, 9 (1904), No. 4, pp. 255–272*).—The resources of Australia are described and discussed.

Wages and cost of living (*U. S. Dept. Com. and Labor, Bureau of Labor Bul. 53, pp. 703–932*).—As shown by data regarding the incomes and expenditures of 2,567 families, collected in 33 States during the year 1901, the average expenditure for food was $326.90 per family, or 42.54 per cent of the expenditure for all purposes. Among other data the article contains statistics of retail prices of the more important foods, wages, hours of labor, etc.

60 per cent of whom are said to be engaged in scientific investigation and its application to the farm, the orchard, and the garden. It will thus be seen that there are now about 300 persons connected with the investigation work of this Bureau alone, a number which far exceeds the total number of men in these lines at all of the experiment stations.

Awards to Collective College and Station Exhibit at St. Louis Exposition.—The following is a list of the awards granted to institutions and individuals on exhibits which formed a portion of the Collective Exhibit of the Colleges of Agriculture and Mechanic Arts and the Experiment Stations:

Grand prizes.—(1) Association of American Agricultural Colleges and Experiment Stations, collective exhibit of the colleges and stations, made by the committee of the association; (2) section of agronomy, in charge of J. I. Schulte, collective exhibit showing courses of instruction, and methods and results of investigations on field crops; (3) section of horticulture and forestry, in charge of S. B. Green, collective exhibit illustrating courses of instruction, and methods and results of investigation in horticulture and forestry; (4) section of economic entomology, in charge of C. P. Gillette, collective exhibit illustrating courses of study in entomology, and collection of economic insects; (5) dairy laboratory, in charge of E. H. Farrington; (6) sugar laboratory, in charge of W. C. Stubbs; (7) plant laboratory, in charge of W. H. Evans; (8) Alabama Station, exhibit showing cotton experiments; (9) Connecticut State Station, tobacco exhibit, tent model illustrating the culture of tobacco under shade, and grass garden exhibit, by E. H. Jenkins; (10) Illinois Station, corn breeding experiments, by C. G. Hopkins; (11) Louisiana Station, exhibit illustrating cane sugar investigation; (12) Minnesota Station, wheat breeding exhibit, by W. M. Hays; (13) Missouri Station, models representing the results of experiments in cattle feeding; (14) Missouri University, models showing comparative hardiness and phenology of peach twigs of different colors, and winter forcing of asparagus in the open field; (15) University of Missouri, cultures of mushrooms and other fungi, by B. M. Duggar; (16) Pennsylvania Station, working model of respiration calorimeter for domestic animals; (17) University of Wisconsin, dairy instruction and results of investigation; (18) S. M. Babcock, of Wisconsin, the original Babcock milk tester; (19) Office of Experiment Stations, statistics, charts, and publications relating to the American stations and the Office of Experiment Stations; (20) Bureau of Education, charts and publications.

Gold medals.—(1) Section of animal husbandry—investigation, in charge of H. P. Armsby; (2) section of animal husbandry—instruction, in charge of Thomas F. Hunt; (3) section of fertilizers, in charge of E. B. Voorhees; (4) section of plant pathology, in charge of F. C. Stewart; (5) section of rural engineering, in charge of Elwood Mead; (6) section of veterinary medicine, in charge of D. S. White; (7) soils laboratory, in charge of M. F. Miller; (8) Arizona Station, collection of date palms and date-palm products, by R. H. Forbes; (9) B. C. Buffum, of Wyoming, automatic water register; (10) California University, soil samples and investigations, by E. W. Hilgard; (11) Connecticut State Station, collection of pure vegetable proteids; (12) Connecticut Storrs Station, cultures of milk bacteria, by H. W. Conn; (13) Cornell University, exhibit of root crops; (14) Cornell University, apparatus for photographing cultures of bacteria and fungi, by G. F. Atkinson; (15) University of Illinois, photographs and records showing relative efficiency of dairy cows, by W. J. Fraser; (16) Maine Station, study of comparative value of hens for egg production; (17) Michigan Agricultural College, models of fruits, collection of photographs and models illustrating work and results in horticulture and forestry; (18) University of Minnesota, model greenhouse laboratory bench, and forestry exhibit; (19) Missouri Station, breeding cage, photographs of laboratories and equipment for work in economic entomology, and collection of beneficial insects; (20) New Jersey Stations, typical soils and ferti-

lizers; (21) New York State Station, charts and graphic representation of investigations on sources of milk fat; (22) New York State Station, charts showing effect of temperature in curing and paraffining cheese, and losses in manufacture, by L. L. Van Slyke; (23) New York State Station,[a] exhibit showing correlation between specific gravity of seed and germinating power and vigor of resulting plant, models of grapes and grape pollen showing correlation between character of pollen and self-fertility of the variety; (24) New York State Station, collection of commercial feeding stuffs, illustrating inspection work; (25) North Dakota Station, exhibit of flax breeding and of root systems; (26) Ohio State University, collection of normal and diseased bones from horses and oxen illustrating more common diseases and fractures; (27) Purdue University, apparatus for recording the growth of plants, by J. C. Arthur; (28) Tennessee Station, apparatus and investigations on effect of fungicides on foliage, by S. M. Bain; (29) Texas Agricultural College, cages for breeding insects, the boll weevil and its injuries, and card system of keeping notes and records; (30) Utah Agricultural College, exhibit of work in domestic science; (31) Virginia Station, pure cultures for use in fermentation industries, by W. B. Alwood; (32) Washington Station, results of wheat breeding, illustrating Mendel's law.

Silver medals.—(1) Section of biological sciences, in charge of G. E. Stone, collection illustrating work in biological sciences at the land-grant institutions; (2) section of inspection work, in charge of M. A. Scovell, collection illustrating inspection work of the stations; (3) Arkansas Station, exhibit showing experimental work with cowpeas; (4) Connecticut State Station, wood engravings showing the microscopic structure of cattle feeds; (5) Hampton Normal and Agricultural Institute, courses of instruction, and samples of student work; (6) Hawaii Station, collection of fruits illustrating improvements; (7) Kansas Agricultural College, exhibit of cereals and forage crops and root systems of plants; (8) Kansas Agricultural College, collection of woods for post purposes, illustrating rate of growth; (9) Kentucky Station, exhibit of hemp; (10) Maine Station, freezing microtome, by W. M. Munson; (11) Maine Station, crossing and improvement of types of tomatoes and blueberries; (12) Michigan Agricultural College, materials showing instruction in domestic science; (13) University of Minnesota, courses of instruction in domestic science and sewing; (14) University of Missouri, influence of birth weight of animals on subsequent growth; (15) New Jersey Station, results of experiments on forage crops for dairy cows; (16) New Mexico Station, photographs and charts showing benefits from arsenical sprays for codling moth, and the number of broods; (17) Cornell University, poultry breeding for egg production, and trap nests; (18) North Carolina Station, specimens and charts illustrating feeding value of cotton-seed products; (19) Ohio State University, apparatus instruction in for soils; (20) Rhode Island Station, photographs illustrating life habits of the apple maggot; (21) Utah Station, model of irrigation farm, and model vegetation house; (22) Utah Station, centrifugal apparatus for mechanical analysis of soils; (23) Vermont Station, charts illustrating composition and comparative value of silage, and analyses of butter produced on different rations; (24) Vermont Station, maple-sugar making; (25) University of Wisconsin, soil aspirator and apparatus for determining relative rates of flow of air through soils of different texture and structure; (26) Wisconsin University, instruction and investigation in drainage and irrigation; (27) Wisconsin Station, feeding value of corn by-products.

Bronze medals.—(1) Section of home economics, in charge of Maude Gilchrist, collective exhibit illustrating courses of instruction in home economics, with samples of students' work; (2) section of rural economy, in charge of F. W. Card, collection illustrating courses of study in rural economics; (3) Clemson Agricultural College, exhibit of evaporated sweet potatoes; (4) Connecticut State Station, specimens of plant diseases; (5) Connecticut Storrs Station, effect of cleanliness of milking, by

[a] This award subsequently raised to grand prize.

At the head of the staff is R. B. Greig, professor of agriculture, economic science, and engineering field work. In addition to the instruction given in the college it is planned to establish "if possible research stations or experimental farms."

Smith Agricultural School.—According to a note in the *Amherst Record*, at the coming city election in Northhampton, Mass., the city will be called upon to elect three persons who shall serve as "superintendents" of the "Smith Agricultural School," to be established with funds bequeathed under the will of the late Oliver Smith. Oliver Smith died in 1845, leaving $30,000 for the establishment of "a model farm and an experimental farm where worthy young men could make a study of agriculture in its various branches, and also a school where a young man could be trained in mechanics." Under the terms of the will the fund was to be allowed to accumulate for 60 years, and will therefore become available next year, when it will amount to approximately $300,000. It is stated that the provisions of the will are not so specific as to prevent considerable latitude on the part of those charged with the execution of the bequest. The general character of the school will therefore depend quite largely upon the "superintendents" who are elected.

New Agricultural Institution in Canada.—Sir William C. Macdonald, of Montreal, who has taken a deep interest in rural education and recently contributed funds for the establishment of concentration schools as an experiment, has decided to establish the Macdonald Foundation for Rural Education in Ste. Anne de Bellevue, 20 miles west of Montreal. A site of about 700 acres of first-class land, with fine exposure overlooking the Ottawa River, has been purchased. Prof. James W. Robertson, Commissioner of Agriculture and Dairying of the Dominion Government, will be at the head of the new institution.

It is proposed to have three departments, i. e., of research, of instruction, and of farms. The department of research will comprise research work in the sciences as related to agricultural and horticultural operations and to rural life generally. The department of instruction will provide long and short courses, and will furnish a headquarters for advanced education bearing upon rural life in Canada. In addition to carrying on work along lines somewhat similar to those followed at the best colleges of agriculture, there will be a division of household science, provision for special courses in nature study for teachers of rural schools, and a division of manual training.

The department of farms will provided for (1) a dairy farm, (2) a meat producing farm, and (3) a "small cultures" farm. Each of these will be arranged, equipped, stocked, manned, and managed so as to illustrate the best known systems and methods of profitable agriculture. Within each farm there will be a series of small farms of from 1 to 5 acres. Apprentices will be received and, in addition to the general work of the larger farms, will be given charge of these small farms for actual practice work. These small practice farms are an outgrowth of experience with school gardens at rural schools, where a plat is assigned to each child.

The main buildings will be constructed in a fireproof manner, and will include residences for men and women students. The whole expense of establishing this institution will be borne by Sir William Macdonald, who will also endow it.

Butter Control Stations in the Netherlands.—A recent publication of the Agricultural Department of the Netherlands describes the butter control stations, which have lately been established by agricultural societies and dairy associations, under the general supervision of the provincial governments. These stations are designed to keep down the adulteration of butter, and to protect honest manufacturers and dealers by exercising control over their products and issuing a guarantee of purity. There are at present seven of these control stations and another is being organized. At the head of each station is a chemist as director, with as many analysts as may be necessary and one or more inspectors. These inspectors take samples of the butter and all materials used in its manufacture in the butter factories or sales rooms

which have submitted to the control. This inspection is extended to butter sent out by these manufacturers or merchants, and the control may also include a guarantee as to water content as well as purity of ingredients. The government regulations provide for the use of a stamp upon the product of the factories or sales rooms which have placed themselves under the control of these stations, which is equivalent to a "mark of guarantee." Paper stamped with this guarantee is to be obtained under certain conditions, and penalties are provided for the use of this guarantee except on a product which has been produced or sold under the control of the stations.

Elementary Agriculture.—Elementary agriculture and horticulture are being introduced into the public school at Westbury Station, N. Y. This school has an enrollment of 250 pupils, and the faculty of 7 teachers has been selected with a view of securing those familiar with manual training methods and school garden work. The school grounds, which contained originally over 70 shade trees, have been planted with about 80 shrubs, 50 vines, and 500 herbaceous plants.

The Territorial Board of Education of Oklahoma is preparing a course of study to be used in the rural schools, and is planning "to give such a place as is wise and practicable to instruction in agricultural education in these schools."

Course of Lectures on Poultry Raising.—A "Poultry School," including lectures and practical demonstrations on profitable poultry raising, has been inaugurated by the Young Men's Christian Association of Brockton, Mass. The course includes seven lectures, and is given as a part of the educational work of that association. Among the lecturers are Dr. A. A. Brigham, of the Columbia School of Poultry Culture, and Dr. Cooper Curtice, of the Rhode Island College and Station. "The course is planned to fit the needs of all who keep fowl, whether the number be large or small, and will, therefore, be of interest to women as well as men, young people or those further along in years."

American Forest Congress.—A call has been issued for an American Forest Congress to be held in Washington, January 2–6, 1905, under the auspices of the American Forestry Association. The purpose of this congress is to establish a broader understanding of the forest in its relation to the great industries depending upon it; to advance the conservative use of forest resources for both present and future needs of these industries, and to stimulate and unite all efforts to perpetuate the forest as a permanent resource of the nation. The subjects to be considered, each of which will receive attention of a separate session, are as follows: (1) Relation of the public forest lands to irrigation; (2) relation of the public forest lands to grazing; (3) the lumber industry and the forest; (4) importance of the public forest lands to mining; (5) forestry in relation to railroad supplies; (6) national forest policy, and (7) State forest policy. The president of the congress is the Hon. James Wilson, and the secretary of the committee of arrangements is Mr. William L. Hall, Atlantic Building, Washington, D. C. The President of the United States will address the congress at a special meeting to be held in the Lafayette Theater, and will receive the delegates in a body at the New Year's reception at the White House. The congress will include delegates from a large number of organizations and bodies representing interests related to forestry, but all who are interested in the ends which it aims to secure are urged to attend the meetings.

Conference of Horticulturists.—A national conference of officers and workers of State horticultural societies was held in the rooms of the Palace of Horticulture on the Exposition Grounds at St. Louis, October 26. The purpose of the conference was the organization of a society which should have the business end of the horticultural interests of the State and Nation in view. A permanent organization was effected, and an executive committee appointed to formulate a constitution and by-laws for the society, to arrange a programme, and to fix upon a date and place for the next meeting. It was suggested that the society meet in a body with the American Pomological Society at its biennial convention, and this suggestion met with general approval.

Miscellaneous.—Announcement is made of a cooperative study of the peony by the horticultural department of Cornell University and the American Peony Society. A study will be made of all the varieties of peonies that it is possible to secure at the present time. The study will extend over a sufficient period of years to enable the investigators to cover the nomenclature, botany, and culture of this flower.

We learn from *Science* that Henry S. Graves, director of the Yale School of Forestry, has been commissioned by the Bureau of Forestry to undertake inspection work in the Philippines, and will also undertake commissions in India for the Forestry Bureau in the Philippines. He left New York December 3, and will return early in May. During the winter his courses will be conducted by Dr. Bernhard E. Fernow, formerly director of the Cornell School of Forestry.

At a meeting of the governors of the Southeastern Agricultural College at Wye, held on Monday, October 24, it was decided, according to *Nature*, to develop further the forestry department, for which a grant will be sought from the Board of Agriculture.

C. D. Howe, assistant in botany in the University of Chicago, has been appointed instructor in botany in the Biltmore Forest School, Biltmore, N. C., and will begin his new duties on January 1.

A department of agricultural-chemical technology has been established in the Polytechnicum at Budapest, and Dr. Thomas Kosutány, director of the Chemical Central Station and the Chemical Agricultural Institute, has been placed in charge of the new department.

Prof. Dr. Franz Tangl, professor of physiological chemistry at the University of Budapest and one of the leading European investigators in the physiology of animal nutrition, has been appointed professor of physiology at the University of Innsbruck.

Dr. K. Windisch, of Berlin, has been appointed director of the agricultural institute at Hohenheim.

Among the honors conferred by King Edward on the occasion of his last birthday was that of Companion of the Order of Saint Michael and Saint George (C. M. G) upon Francis Watts, director of agriculture in the Island of Antigua and agricultural chemist for the Colony of the Leeward Islands.

O

EXPERIMENT STATION RECORD.

Vol. XVI. January, 1905. No. 5.

The winter meeting of the American Association for the Advancement of Science has become one of the leading scientific events of the year. The association is so broad in its scope and its affiliations that it furnishes a common meeting ground for the representatives of almost every branch of pure and applied science. It brings together an enthusiastic and earnest body of men of science, who take advantage of this opportunity for meeting their colleagues and those engaged in related branches of science, of listening to papers and discussions on subjects of broad interest, and of enjoying the social features which are always in evidence at these meetings.

The meeting at Philadelphia last month was a representative one in all respects. It was attended by nearly a thousand persons, who were members either of the American Association itself or some of its affiliated societies. Both from a scientific and a social standpoint it was an eminently successful and satisfactory meeting.

Agricultural science was well represented at the various meetings of the botanists, the chemists, the economic entomologists, the Society for the Promotion of Agricultural Science, and the Society for Horticultural Science. The programs of several other sections and societies also contained a considerable number of papers relating to various branches of agricultural science, and even the address of the retiring president dealt in part with agricultural development in its relation to economic problems. The theme of President Wright's address was Science and Economics, and it concerned itself with the influence of science in modifying and extending the theories of economists, and what science might do in working out the great laws of the business world.

Concerning the Malthusian doctrine, it was pointed out that the author of the theory "did not anticipate and could not foresee the great changes which would come in the way of the cultivation of the land and in other ways to increase the food supply relative to the increase of population. . . . The broadening of the area of supply through discovery, and the taking up of vast tracts of land, were the immediate means of depriving the doctrine of its force, but later on intensive agriculture and the discoveries of science succeeded in relegating the theory to the past."

Closely allied to this doctrine is the law of diminishing returns, which, although it is fundamental and all-embracing, is usually applied to the agricultural industry. The speaker pointed out that through the introduction of machinery and the application of new principles in agriculture, science has greatly extended and regulated agricultural production and has modified the law of diminishing returns "to such a degree as, for a while at least, to rob it of its peculiar influence in increasing cost or retarding the supply from the cultivation of certain kinds of land."

In connection with the labor question stress was laid upon the relation of food to the efficiency of labor, and the speaker laid down the principle that the economy of food must be treated from two standpoints—the physiological and the pecuniary. "These elements can not be separated," he said, "if we are to understand fully the effects of different foods upon the efficiency of labor and the capacity of labor to sustain itself. These things should form a part of political economy; they are certainly far more valuable than any treatise upon rent or interest." The conviction was expressed that the various agencies now at work under the patronage of the Government, scientific institutions, colleges, and universities will furnish a body of facts that will clearly and definitely decide the great question of efficiency of labor so far as food is concerned.

The Philadelphia meeting marked the twenty-fifth anniversary of the Society for the Promotion of Agricultural Science, which was established by a body of men who felt the need of an organization where the methods and results of agricultural experimentation might be discussed. In his presidential address this year Dr. William Frear briefly reviewed the development of agricultural science in various directions, which began with chemistry and was later extended to physics and biology, and called attention to the necessity for cooperation between the different branches of science in extending the boundaries of knowledge relating to the science of agriculture. The calls upon the investigators are becoming more numerous, and the problems presented to them are increasingly complicated, so that we now recognize that they must be approached from various points of view.

Referring to the practical character of American investigation in many lines, rather than its being conspicuously scientific, the speaker stated that this condition was reflected in our schemes for agricultural education, which have laid special stress upon the art. He made an appeal for greater attention to science as the foundation of the art, and said in conclusion: "Modern agricultural education will fail unless the science is made to keep equal pace with the art, both in our schools and in our experiment stations. The art of the future must depend upon the science of the future, as well as upon that of to-day, and the

science of the future must develop not only from the demands of the practitioner of the art, but from the productive energies of the scientist."

The presidential address of Prof. L. H. Bailey before the Society for Horticultural Science dealt with the question, What is horticulture? In answering this he showed it to be primarily a biological subject whose fundamental relationship is with botany, although latterly it has been correlated with agriculture rather than with botany. Horticulture was compared in its relations to botany with that of electrical and other engineering to physics. It was suggested that the present tendency to return to unit courses of biology might result in the abandoning of the term "botanist" as designating the occupant of a professorship, and that in its place would be specialized biologists in various phases of the subject. Among these would be reckoned the horticulturist, connecting plant biology with the affairs of men. Going a step further, the speaker prophesied the differentiation of horticulture, as has been the case with agriculture, with horticulturists representing different branches of the industry, such as pomology, ornamental gardening, fruit manufacture, and the like.

The general subject of horticulture was divided into three phases—the biological or science side, the affairs or commercial side, and the art and home side. The speaker affirmed that the opportunities of horticulturists on the science side are just beginning to be recognized and that most of their work has been of a temporary and superficial character. Real horticultural research is only begun, and the field is concreting itself and attracting trained men to it. Out of this more profound research of the future, it was suggested, might come a clearer conception of plant breeding and its relations to the grower and to the manipulation of the soil, a new plant physiology, preferably a joint product of the botanists and the horticulturists, and important contributions to the subject of evolution, derived inevitably from study of the species which we now cultivate and the extension of effort to species not yet domesticated.

In addition to the horticulturist's biological work, the speaker pointed out his mission in cultivating the art impulses, as expressed in plants in the home and in the garden, in the parks, and along the streets and highways. His energies are expended in every way in which plants appeal to men. As a teaching profession the subject was divided into two great phases—the teaching of those things relating to the art and the craft, and aiding in bringing the child into relations with its environment. "In all these generations," he said, "we have been training the reflective and passive faculties; we shall now train also the creative and active faculties. . . . The child will be trained to use his hands, to plan, and to reason from actual problems. Then he will be resourceful and will have power."

A résumé of the papers of agricultural interest which were presented at the meeting of the American Association will be given in the next issue. Many of these will naturally be published in full in various scientific journals. Indeed, even to many persons who attended the meeting the published form will often prove quite as profitable, especially in the case of papers presented in much detail. In a large meeting of this sort, where so much has to be crowded into three or four days, delegates are satiated with papers and fatigued, so that they are compelled to select those of more special interest to them, and for the rest can only carry away certain generalizations. With the multiplicity of organs which we now have for the publication of scientific papers, there is less excuse than formerly for the presentation of progress reports in the ordinary lines of research or upon relatively narrow subjects, whose publication in a scientific periodical would serve every purpose. At all events, the presentation of such subjects should be brief and confined to a summary of the findings which have a bearing on the general progress of investigation.

It has frequently been suggested that the time of the meetings might well be reserved for papers presenting some new features of a subject of widespread interest, or involving principles in the progress of the science, or conferences or discussions on some topics in which an exchange of views by selected speakers would help to illuminate the subjects and suggest points where the evidence needed strengthening. A case in point is the annual discussion of the American Society of Naturalists, which always forms an interesting feature of the American Association meeting. These discussions are participated in by a number of men selected beforehand, and representing different branches of science or different points of view.

This year the subject of the discussion before that society was The Mutation Theory of Organic Evolution, which was treated from the botanical, cytological, anatomical, and paleontological standpoints, and also from that of animal breeding. Such an exchange of views can hardly fail to be instructive and helpful, and the oral presentation by prepared speakers lends an added interest.

We are prone to multiply scientific organizations and to subdivide into specialties, but in doing so much of the advantage of contact with men representing the more general aspects of science is lost. Too close specialization in work and in association tends to narrowness, and the failure of the investigator to consider his own work and that of others in their broad relations endangers the accuracy of his generalizations.

Already there is a revulsion against so large a number of independent societies, and we find a movement toward a union of common interests or the holding of joint sessions. At the meeting last month

the botanists took steps toward a union of their interests, now represented by three societies which meet simultaneously, into a single organization to be known as the Botanical Society of America.

Too great specialization is one of the dangers of the younger workers in applied science, and there have been some evidences of this in the forces of the experiment stations. The station men are often, by reason of their location and the character of their duties, to a certain degree isolated and cut off from the opportunity for contact with men in their respective lines. To them quite as much as the worker in pure science the broadening influence and the stimulus which come from association with men of science in their own and related lines is important, and tends to higher and better work. It is gratifying, therefore, to note the attendance of station men at these meetings in increasing numbers, and to find them occupying a prominent place in their respective sections or affiliated societies.

The social or contact side is undoubtedly one of the most helpful features of these meetings, for it not only enables men of science to come to know one another better, but it extends scientific affiliations and promotes the scientific spirit so essential to all investigation.

In the retirement of Dr. W. C. Stubbs from the directorship of the Louisiana Experiment Stations, the South loses one of its strongest and most successful workers in the domain of agricultural experimentation. One of the pioneers in this work, he combined with his scientific attainments an aggressiveness and a knowledge of practical affairs which made him a capable organizer, a forceful administrative officer, and an exceptionally efficient and influential investigator.

For twenty years past he has given his best efforts to upbuilding the agriculture of the State and placing its leading industry upon a more scientific basis. The multiplicity of duties imposed upon him have kept him constantly overworked and greatly restricted him in the higher investigation which was close to his heart. Like many another man in this field, he was sacrificed to the demands of to-day, as a result of the high appreciation and confidence in which he was held; and it was largely due to his indomitable energy and physical strength that he was able to accomplish as much as he did in agricultural science. The desire for more leisure for writing and study is given as the reason for his decision to retire thus early in life, while still in full health and vigor.

The regret at Dr. Stubbs' retirement will not be confined to the State where he served, but will be shared by the surrounding States which felt his influence, and by his colleagues in experiment-station work throughout the country. The latter will miss his inspiration and counsels, and will hope that his interest in the field of work where he has been so conspicuous will not soon be relinquished.

CONVENTION OF ASSOCIATION OF AMERICAN AGRICULTURAL COLLEGES AND EXPERIMENT STATIONS.

E. W. ALLEN, Ph. D.,
Office of Experiment Stations.

The eighteenth annual convention of this association, held at Des Moines, Iowa, November 1–3, was one of the most interesting and profitable meetings which this association has held for many years. It was the first meeting under the new constitution, which reduces the number of sections from five to two, and the advantage of the new plan was very marked in enabling delegates to follow the discussions more closely and in concentrating the deliberations upon questions relating to the administration of the colleges and stations, the general management, and methods of work. An appeal for the formation of a division for horticulture and botany within the section on station work was rejected, and it was made apparent that, inasmuch as the object of these meetings is not the presentation of technical papers reporting specific investigations, but rather the discussion of broad questions of station work and administration and the methods by which these can be made most effectual, there is a distinct advantage in the compact organization. About 150 delegates and visitors were registered.

GENERAL SESSIONS.

The general sessions were presided over by Dr. W. O. Thompson, of the University of Ohio. He delivered the presidential address on the evening of the first day, taking for his theme Some Problems in the Colleges of Agriculture and Mechanic Arts. In this, Dr. Thompson pointed out that the Morrill Act is the original foundation upon which these colleges stand, and it was not expected that the Morrill funds would support the institutions, but that the States would aid in their support. The expenditure of money must inevitably increase, for civilization makes increasing demands upon the citizens—it presents not only its opportunities but its duties as well.

The colleges and stations were shown to stand in a very vital relation to our natural resources, and to their development and preservation; and it was pointed out that they are not for the farming people exclusively, although they will reach them first, but that they have a deeper significance for the whole country. In estimating the full measure of the college and station work it was urged that we must look beyond the mere material results, and consider their influence in its highest sense,

which is the effect on men, in giving them higher ideals of life; and these ideals should become the common property of all the people.

Coming to some of the practical problems of the colleges and stations, attention was called to the conditions in the agricultural communities, the tendency away from the farm, and the fact that many a farmer's boy lacks the opportunity for individual initiative so essential for independent positions. It was urged that farm life must not be the refuge of necessity, and that not all farmers' sons are suited to be farmers any more than all lawyers' sons are suited to that profession. The changes in farm life were noted, such as increased cost of machinery, the labor problem, and the requirement in most localities not only of more capital but of greater intelligence and native ability. Impoverished farm land was pointed to as one of the greatest drawbacks to development. This tends to keep down the price of labor, harbors an inferior population, and threatens the most important conditions of rural life.

The point was made that intelligent operation of the farm is now necessary for any margin of profit. The fallacy that unintelligent men can make successful farmers or satisfactory farm laborers was severely arraigned, and it was urged that a much lower grade of intelligence is required to dig a sewer ditch in the city than a ditch for tile draining on the farm, because farm work "requires men who are equal to their own emergencies and who can assume their own responsibilities." It should be recognized that intelligence on the farm will produce results just as surely as elsewhere; and some manifestations of the tendency toward more intelligent farming were cited.

Conceding that the time is past for unintelligent farming in most parts of this country—that farming requires an education, the problem of how to supply this need was declared to be the problem of agricultural education; and here the point was made that the enterprise is usually working under the disadvantage of too little money. It is not generally appreciated that agricultural education must necessarily be a very expensive form of education. "The agricultural college is an expensive thing in itself, because it centralizes all the expensiveness of ignorance under an organization that proposes to remove ignorance and supplant it with intelligence and skill." The need of ample funds for this branch of education was enlarged upon, and it was pointed out that the limitations of the colleges have been a very serious handicap to the development of agricultural education in this country.

Coming to elementary instruction, a strong plea was made for the introduction of agriculture in the rural schools, and the duty devolving upon the agricultural colleges of furnishing the inspiration and the initiative for this movement was pointed out. Agriculture differs from other industries in that it will not take care of itself, like banking or engineering, and hence a propaganda must be carried on for it. An

extension department of the college was advocated to work up and stimulate agricultural education in the rural communities. "The problem of agricultural education will not be solved until the agricultural colleges have been brought into close and vital relations to the agricultural populations."

The report of the executive committee, submitted by Dr. H. C. White, chairman, described the efforts of the committee in behalf of the "mining bill" and the bill for the further endowment of experiment stations, now pending in Congress, and the conferences of the committee with the Secretary of Agriculture and a committee of the Department on matters relating to cooperation with the stations.

Regarding cooperation, no concrete conclusion had been reached, but it was thought that much had been accomplished in the direction of a mutual understanding, and the continuance of these conferences was recommended. In order that Congress may be advised of the character and importance of the work which the stations are doing, it was recommended that the executive committee be authorized to appear before the agricultural committees of Congress and explain these matters.

This topic came up for consideration at a later session, in connection with the report of the committee on cooperation, by President E. A. Bryan, and a resolution introduced by Dr. W. H. Jordan, was adopted as follows:

Resolved, That this association emphatically recognizes the great services which the National Department of Agriculture is now rendering to the science and practice of agriculture, and to the institutions here represented, by its helpful cooperation with the agricultural experiment stations, and by its able coordination and wide dissemination of the information secured within itself and by the experiment stations; and this association views with disfavor any movements which, either by legislation or otherwise, shall tend to disturb or lessen the mutually advantageous relations which now exist between the Department of Agriculture and the experiment stations of the several States.

Resolved, That this association is firmly of the opinion that the continuation and development of these mutually helpful relations between the Department and the stations, and the maintenance and progress of efficient research in agricultural science, demand that the autonomy and paramount position of the stations as institutions of research and experimentation be inviolably maintained within their respective States, in accordance with the terms and spirit of the Hatch Act.

Resolved, That in order that Congress may be properly informed as to the work of the agricultural experiment stations and its great value to agricultural practice, and to promote satisfactory relations between the Department of Agriculture and the experiment stations, the executive committee of this association is hereby instructed to request a hearing before the proper committees of Congress for the purpose of presenting the work and claims of the agricultural experiment stations, and to continue conferences with the honorable Secretary of Agriculture relative to cooperation between his Department and the stations.

The discussion of this resolution was carried on with the utmost frankness and good feeling, and with full confidence that a way would be found which would prevent any apparent antagonism or duplication.

The report of the treasurer, Dr. E. B. Voorhees, showed total receipts (including balance on hand) of $1,794.26, and expenditures amounting to $1,160.34, leaving a balance in the treasury of $633.92.

The report of the bibliographer, Dr. A. C. True, enumerated some of the notable works and bibliographies relating to agricultural science which had appeared during the year; and the report of the committee on indexing agricultural literature mentioned especially the card index to periodicals relating to agricultural science, which is being prepared in the Library of this Department.

The committee on the collective college and station exhibit at St. Louis, through Dr. W. H. Jordan, chairman, presented a progress report briefly enumerating some of the features relating to the exhibit in the Palace of Education, and the "outside exhibit," demonstrating the methods of work with plants and animals. A summary of the awards was presented, which have already been enumerated in this journal (E. S. R., 16, p. 414). There was some discussion as to the final disposition of the report, but no definite action was taken, and authority was given the committee to close the exhibit.

The committee on uniform fertilizer and feeding stuff laws submitted a brief report, through Dr. H. J. Wheeler, chairman. It reaffirmed its recommendation of last year, that in the case of feeding stuffs the State should make direct appropriation for defraying the expense of the inspection. Upon the point referred to the committee as to whether the results of fertilizer analysis should be reported in terms of ammonia or nitrogen, phosphoric acid or phosphorus, potash or potassium, the committee reported that in view of the fact that many of the States had passed laws using the words ammonia, phosphoric acid, and potash, and as these terms had become fixed, the change to nitrogen, potassium, and phosphorus was impracticable. There was shown to be considerable lack of uniformity at present, and it was stated that the Association of Official Agricultural Chemists has a committee considering the question of nomenclature. In view of this fact a committee on chemical nomenclature was appointed by the chairman of the section of station work, to confer with the similar committee of the Association of Official Agricultural Chemists. The committee appointed consists of C. G. Hopkins, H. J. Wheeler, A. T. Neale, R. J. Davidson, and H. Snyder.

The committee on methods of seed testing reported, through the chairman Dr. E. H. Jenkins, that during the year the rules for seed testing had been revised and printed as a bulletin of this Office.

The committee on military instruction in land-grant colleges submitted a brief report through President G. W. Atherton, which was

referred to the section for college work, as this subject was upon the programme of that section (see below).

The committee on methods of teaching agriculture presented a report on The Teaching of Agriculture in the Rural Common Schools. This reviewed the development of industrial training in the common schools, the movement to introduce agriculture into rural schools, and the various forms which this work has taken; discussed some obstacles in the way, the object of teaching agriculture, and concluded with a syllabus of an elementary course in agriculture.[a]

The report of the committee on graduate study reaffirmed the plan of conducting a graduate school under the auspices of the association, and recommended that the school be held in future every two years, beginning, if possible, with the coming summer, that each agricultural college be requested to contribute a small sum of money, say $25, to aid the maintenance of such a school, and that the committee be empowered to arrange for the holding of such schools. This report was adopted.

The report of the committee on rural engineering, presented by Dr. W. E. Stone, chairman, reported the progress which has been made during the year in developing courses in agricultural engineering and farm mechanics. Courses in these subjects are now offered by the agricultural colleges of California, Colorado, Illinois, Indiana, Iowa, Kansas, Minnesota, New York, North Dakota, Wisconsin, and Wyoming. Some examples of the benefits of instruction and investigation carried on by these departments were presented. The report recognized it as exceedingly important at this time that a bureau or division of agricultural engineering be organized in this Department, to aid the colleges which now have courses in agricultural engineering, to collect the data which such colleges are obtaining in their experimental tests, to carry on original research, and to establish laboratories for practical tests of implements, etc.

Prof. W. M. Hays presented the report of the committee on animal and plant breeding, which described the formation of the American Breeders' Association, now numbering 275 members, 15 of whom are life members.

In a scholarly address on The Social Phase of Agricultural Education, President Kenyon L. Butterfield laid down the broad proposition that "the permanent function of the agricultural college is to serve as a social organ or agency of first importance, in helping to solve all phases of the rural problem."

The introduction of rural economics and the spirit which it stands for was stated to be far more than the adding of three or four subjects of study to the agricultural course, but to involve the very function

[a] Since issued as Circular 60 of this Office.

and policy of the college itself. "The whole spirit and method of the agricultural college must be 'socialized.'" The first requisite to this was indicated to be the conscious ideal or purpose of being "all things to all farmers," and the second, organization. The greatest need of American agriculture to-day was declared to be social leadership, and it was argued that the college should train men and women for this service. Finally, "to carry out the function of the agricultural college, we need a vast enlargement of extension work among farmers. This work will not only be dignified by a standing in the college coordinate with research and the teaching of students, but it will rank as a distinct department with a faculty of men whose chief business is to teach the people who can not come to the college."

Director William Saunders of the Central Experimental Farm, Ottawa, Canada, delivered an address on The Upbuilding of Agriculture. In this address the speaker treated of the development of colleges of agriculture and experiment stations, and the great work of the United States Department of Agriculture. Coming to the work in Canada, he described the various agencies at work there and noted many of the profitable results of the experimental work in Canada and British Columbia, paying special attention to the introduction and improvement of cereals by selection and breeding.

President James K. Patterson, representing a committee appointed for that purpose, presented an eloquent tribute to the late Major Henry E. Alvord, recording the high esteem and affection in which he was held by the association, and testifying to his eminent services to agriculture in the various public and private capacities in which he served. "A sincere friend, a patriot, a soldier without sectional bitterness or prejudice, an efficient administrative officer, and a wise counselor, with a lofty ideal of duty and of honor, this association discharges a duty to itself by bearing hearty testimony to his conspicuous worth as a citizen and as a man."

Resolutions were passed by the association tendering to the Hon. H. C. Adams and Hon. F. W. Mondell the hearty thanks of the association for their earnest, intelligent, and well-directed efforts in behalf of the bill for increasing the appropriation to the experiment stations and the "mining bill," and pledging the hearty cooperation and assistance of the association. By another resolution the executive committee was authorized to use its efforts to secure the passage of these bills and to give precedence in this to Mr. Adams's bill.

Resolutions instructing the executive committee to endeavor to secure the franking privilege for engineering experiment stations and for the extension departments of the colleges were discussed at considerable length, but were finally withdrawn, as action was not deemed expedient at this time.

An invitation was received for the association to hold its next meeting at Portland during the Lewis and Clarke Exposition.

The association adjourned after the morning session of the third day and proceeded by special train to the State College at Ames, where a most interesting and profitable afternoon was spent in looking over the buildings and equipment of this institution, especially its agricultural and engineering departments. Here the large amount of live stock kept primarily for instruction purposes—over 30 head of horses of various breeds and types, the new pavilion for stock and grain judging, the well-equipped new department of farm mechanics, the commodious soils laboratory, the new dairy building in process of construction, and the plans for the new agricultural building to cost from $250,000 to $300,000, typified the rapid advance which is making in the material equipment for agricultural education, which will place that department on a par with engineering at the better institutions.

The officers elected for the ensuing year were as follows:

President, E. B. Voorhees, of New Jersey; vice-presidents, J. C. Hardy of Mississippi, K. L. Butterfield of Rhode Island, C. D. Woods of Maine, E. R. Nichols of Kansas, and E. Davenport of Illinois; secretary and treasurer, J. L. Hills, of Vermont; bibliographer, A. C. True, of Washington, D. C.; executive committee, H. C. White of Georgia, J. L. Snyder of Michigan, W. H. Jordan of New York, C. F. Curtiss of Iowa, and L. H. Bailey of New York.

Section on college work and administration.—Chairman, R. W. Stimson, of Connecticut; secretary, K. L. Butterfield, of Rhode Island.

Section on experiment station work.—Chairman, H. J. Patterson, of Maryland; secretary, M. A. Scovell, of Kentucky.

SECTION ON COLLEGE WORK AND ADMINISTRATION.

The question as to how far the land-grant institutions may or should engage in teaching elementary subjects not generally recognized as belonging to the college curriculum was discussed at length, and brought out a quite marked difference of opinion. The discussion was opened by a paper on this subject by President W. O. Thompson, who defended and justified those colleges of agriculture which have found it necessary to begin their elementary instruction quite low down, owing to lack of proper training in the public schools, and also commended the short courses. From the standpoint of the Morrill acts, he assumed that this elementary instruction was quite within the limits of the law, and granting this, he held that the manner of the teaching was wholly a matter of local jurisdiction.

In discussing this paper, President R. H. Jesse took the opposite ground, and maintained that the use of Federal funds for secondary education was a misappropriation, since the money was given for collegiate instruction. He disapproved of the establishment of agricul-

tural high schools or preparatory departments for the agricultural colleges, and contended that the remedy for the condition lay in the improvement of the public school system by the introduction of agricultural studies. "In Missouri we are risking our entire future on that doctrine, that the college of agriculture is going to rest on the public high school, and we are going to make the public high school agricultural as far as it ought to be agricultural." This was acknowledged to be the long way, but it was held to be the right way, which would justify itself in the long run.

Prof. L. H. Bailey took a middle ground upon this question, holding that these forms of elementary instruction are entirely warrantable under the Morrill Act, but that short courses do not properly belong in the college and are a temporary expediency, arising from the fact that the land-grant colleges do not articulate with the common schools. He did not advocate duplicating the system of public high schools, but believed the final issue would be to prepare the public schools to prepare for the land-grant colleges, as they now prepare for colleges of arts and sciences. But as this will occupy many years, perhaps a generation, he believed that we must take care of the pressing problems of to-day, and on that ground defended the short and lower-grade courses as temporary expedients. Dean Davenport, of the University of Illinois, explained the plan adopted at his institution, which is to cut away from the rigid courses of instruction leading to graduation, and lower the grade for admission, allowing greater freedom in the matter of electives. He stated that he had abandoned for the time being the high ideals advocated by some, and was endeavoring to demonstrate the practical utility and value of agricultural instruction and to create a demand for it.

Other speakers presented the local difficulty of confining the instruction to a four-year course, and maintained that the short courses had first roused genuine interest and confidence in agricultural education, and that the more elementary grades of work did not obscure the college course. It was held that under present conditions there is a large body of young men who are not and can not be prepared to enter the regular college course, with its rigid requirements for admission, and that for these young men, who come to the college in increasing numbers, special and short courses should be provided.

Closely related to this discussion was the consideration of the question, What Can and Should be Done to Increase the Interest in and Appreciation for the Agricultural Side of Technical Training? The subject was introduced by a paper by President J. L. Snyder, of Michigan, which led to a very animated discussion extending to the whole field of agricultural education.

President Snyder urged that the courses in agriculture must be technical, and that the agricultural department must have equal advan-

tage in equipment and buildings with the other departments of the college or university. He held it to be "the plain and imperative duty of all land-grant colleges to build up strong, independent departments of agriculture." Short courses should be provided for those unable to take the longer courses. The speaker described what was done in Michigan to arouse interest in the agricultural work by maintaining close relations with public schools, advertising the institution in various ways, and running excursions to the college in August, which the past year were attended by about eight thousand people.

Dean Davenport, referring to the one-time idea that agriculture could not be made interesting, suggested the need of more instructors in the subject, and splitting it up into smaller subdivisions. He showed, as a matter of statistics, that in different institutions the number of teachers in agriculture varies at present from 23 or 24 down to two-thirds of a man, and stated that "so far as I know, in these institutions the interest in agriculture on the part of the students is about in proportion to the number of men who are teaching the subject." Referring to the University of Illinois, he stated that the institution offers 73 different lines of instruction in agriculture, all technical, 67 of which are being taught this year; the present year its corps of instructors is giving 44,360 hours of instruction.

He made the point clear that the number of men to be taught should not be the unit in manning the staff of the agricultural department, as it now too often is, but that the true unit is the subject itself. He pointed out that his institution now has more teachers in agriculture than it had students five years ago, when the contention was that more teachers were not needed until there were more students to teach; but he showed that as soon as the number of instructors was doubled the number of students doubled, and he believed that within certain limits it would be so everywhere. He held that it was in the universities to-day that agriculture has the best opportunity, because its courses are more elastic and more opportunities are given for electives; and agriculture being a technical work, he argued, must be largely elective.

Prof. C. F. Curtiss urged concentration in the agricultural courses, rather than too narrow specialization; and other speakers pointed out the distinction between training and education, maintaining that much of the instruction given in agriculture was training simply, and did not involve systematic and fundamental instruction over a broad field, which is essential to education.

While the question as to what the colleges should do to popularize agricultural education was not definitely answered, the discussion served to clarify the ideas on this topic, to some extent, and to bring out the varying conditions in different localities which called for special treatment.

In a paper on What Degrees should be Given for the Completion of

Undergraduate Courses in Land-Grant Colleges? President G. A. Harter advocated the B. S. degree, to be placed on the same level as the B. A. degree in the requirements leading to it. He maintained that the degrees B. Agr. and B. S. A. (bachelor of science in agriculture) should be done away with, and that the tendency to multiply degrees should be resisted. Dr. A. B. Storms contended for the B. S. A. degree for agricultural students as being more definite; while others maintained that that degree recognized the agricultural work as professional, and that distinction should be made between the general academic degrees and professional degrees.

The question as to the intent and purpose of the Morrill Act in regard to military instruction was introduced by a paper by President M. H. Buckham, of Vermont, which traced the history of the incorporation of the military clause in the Morrill Act, and presented such documentary evidence as is to be found relative to the intent and purpose at the time the Act was passed. The special interest in this topic has grown out of General Order 65, issued by the War Department, which prescribes the amount of military instruction which the officers detailed to the colleges for this duty are expected to require. Through failure to comply with these requirements, several institutions have incurred an unfavorable report, which has resulted in the withdrawal of the detail. President Buckham suggested that less emphasis be placed on the manual and technical branches of military training, and more upon the higher, the intellectual topics in the military art, since the students at these land-grant colleges "take military tactics as a part of a liberal education, not to fit them to serve as enlisted men."

The quite lengthy discussion upon this topic showed that with the general advocacy of the importance of military work, and the desire to comply with the law in this respect, there was a quite general dissent from the present requirements of the War Department; and the presidents of several large institutions stated that if full compliance with General Order 65 were insisted upon they should be under the necessity of declining a detail and making provision for carrying out the military instruction in their own way.

A resolution introduced by President Van Hise, of Wisconsin, instructed the executive committee to present the views of the association to the President or the Secretary of War, and this resolution was later passed by the association at one of the general sessions.

SECTION ON EXPERIMENT STATION WORK.

This section considered the general subject of the breeding and improvement of plants and animals, and held a conference on the question of the amount of teaching which it is desirable for station workers to do.

Under the general subject Prof. W. M. Hays, of Minnesota, presented a paper on The Shakespeare of the Species. He pointed out the development of knowledge regarding methods of breeding plants and animals and the working out of some of the underlying principles. A very optimistic view was taken as to the importance of systematic work in breeding, in which there is already widespread interest, and it was believed to have great application in commercial lines. In discussing this paper, the influence of environment—altitude, climate, character of the soil, etc.—was brought out, and the statement made that "the energies of environment are to be considered as important factors, as great perhaps as that of heredity;" and from this it was argued that breeding work should be done in different localities, and species and varieties for these environments developed.

Dr. T. L. Lyon, of Nebraska, spoke upon Improvement in the Quality of Wheat, describing his extensive experiments in selection for protein and gluten. He stated that selection for improvement has not gone hand in hand with selection for yield, because the methods have not been perfected. Analyses of the different heads or spikes showed great differences in nitrogen, so that an analysis of any one head could not be taken as indicating the composition of the plant. Half the number of heads on the plant give a quite close average. There was a slight decrease in the number of kernels in the head and in the weight of the kernels, accompanying an increase in the percentage of nitrogen. The percentage of nitrogen is not a guide to the content of gliadin and glutenin, and if selection is to be made on the basis of gluten content the gliadin and glutenin must be determined. Tables showed that the gluten nitrogen varied from 0.48 to 2.94 per cent. The gluten was found to increase and decrease without change in its quality, since the relation of gliadin to glutenin remained about the same.

Dr. Lyon showed that selection had an effect the first year, as shown by the progeny; and a tendency toward heredity was apparent in the weight of the kernel, the same as in the case of nitrogen content. Since a high yield and high nitrogen content do not go together, it was pointed out that there is danger that in selecting wheat for yield alone the quality will be injured, and it was maintained, therefore, that the quality should be taken account of in breeding or selecting for yield.

Prof. H. Snyder called attention to the difference in values of wheat for various purposes and the lack of standards, and moved the appointment of a standing committee of three on standards for determining the value of cereals. This motion passed, and H. Snyder, C. G. Hopkins, and T. L. Lyon were appointed on the committee.

In a paper on Animal Breeding, Prof. C. F. Curtiss reviewed the work which is now being undertaken in animal breeding. The replies to a circular letter sent out to station men asking about the breeding

work and plans under consideration showed that considerable work in animal breeding has been undertaken, and that the subject is one in which there is much interest. Professor Curtiss expressed the view that the theories and supposed laws of heredity should be tested by extensive and repeated experiments with domestic animals, and that it is desirable to perform this work with the larger rather than the smaller animals, notwithstanding the longer time and greater expenditure which will be involved.

In the conference upon the subject of how much teaching, if any, it is desirable that a station worker should do, there was a lively discussion and a free expression of views, which seemed to be very largely in one direction. In opening the discussion Dr. H. P. Armsby showed that, according to the latest reports of this Office, about 54 per cent of the station workers now do more or less teaching, and that while the proportion differed in different institutions, the tendency seemed to be toward an increase in the number of station men who also teach. He expressed doubt as to the advantage, which is frequently urged, of the station men doing college work, and he was quite emphatic upon the point that while a certain amount of teaching might be advantageous "an uncertain amount is not." He believed that in this agricultural work a man should be chiefly either a teacher or an investigator, and maintained that the two kinds of work call for a different attitude of mind and the use of a different set of faculties, to a certain extent. He held it to be imperative, if the station enterprise is to reach the highest measure of success, that there should be a reform, and that the tendency should be in the direction of less teaching and a differentiation between the station and the school or college of agriculture, in order that the station may be just what the Hatch Act calls for—a department of the college devoted to research.

Dr. W. H. Jordan made the point that the advantage of teaching to the station man depended quite largely upon the kind of teaching to be done, and stated that most of the teaching at our agricultural colleges was the teaching of fundamentals. He denied that the teaching of fundamentals and the drilling of classes for 50 per cent of the time is an advantage to the investigator. He conceded that a small amount of teaching of an advanced character, along specialties with which the station man is dealing, say 10 to 20 lectures a year, might well prove an advantage; but he maintained that "very much of the teaching which we necessarily do in our agricultural colleges to-day is not an advantage but a disadvantage to the investigator."

It developed from the discussion that the plan of requiring this dual service from station men was considered largely one of expediency; and that being the case, it was urged that the teaching should be so arranged on the college schedule as to interfere as little as possible with the time of the station man, and to leave him a part of the year,

or possibly several days each week, entirely free from college work. The advantage to the teacher of carrying on some investigation was pointed out and conceded, but this is obviously another phase of the question. The almost unanimous opinion of the speakers was that the matter has been overdone, and that the general character of the station work has been unfavorably affected by the requirements of too much teaching from men holding important positions on the station staff.

The matter of federating the farmers' organizations and societies in the different States was brought up, and it was shown how these federations have been able to assist the colleges and stations in bringing about an appreciation of their work and in securing favorable legislation. A committee consisting of H. J. Wheeler, C. D. Woods, and H. J. Patterson was appointed to take up the matter in the different States by correspondence.

The programme committee recommended for next year the subject of soil investigations, and the discussion of the question of the extent to which demonstration work should be undertaken by the stations.

RECENT WORK IN AGRICULTURAL SCIENCE.

CHEMISTRY.

The chemistry of proteids, O. COHNHEIM (*Chemie der Eiweisskörper. Brunswick: Friedrich Vieweg & Son, 1904, 2. ed., pp. XII+315*).—The present edition, the author states, has been rewritten and revised, a large amount of new material being added. In its present form it constitutes a summary of available data regarding the chemistry, properties, and structure of proteid bodies, including albumoses and peptones, proteid salts, halogen derivatives and similar bodies, true albumins, proteids, and albuminoids. The numerous references cited throughout the volume constitute an extended bibliography of the subject. A copious index is provided.

The chemistry of wheat gluten, G. G. NASMITH (*Trans. Canad. Inst., 7 (1904), III, No. 15, pp. 497-516*).—Practically the same as a paper abstracted from another source (E. S. R., 15, p. 748).

Concerning isocreatin and its identity with creatin, E. POULSSON (*Arch. Expr. Path. u. Pharmakol., 51 (1904), No. 2-3, pp. 227-238; abs. in Zentbl. Physiol., 18 (1904), No. 13, p. 377*).—According to the author the yellow material which has been called isocreatin is a mixture of creatin with a yellow coloring matter, being identical with creatin in all of its reactions when freed from the coloring matter.

Concerning the estimation of nuclein bases in beet juice, H. W. BRESLER (*Ztschr. Physiol. Chem., 41 (1904), No. 6, pp. 535-541*).—According to the author's investigations the nitrogen of beet juice was made up of 0.29 per cent heteroxanthin, 1.58 per cent guanin, 0.81 per cent xanthin, 0.61 per cent adenin, 0.91 per cent hypoxanthin, and 0.69 per cent carnin nitrogen. The total nitrogen present was 0.2345 gm. per liter.

Methods suitable for the preparation of organic bases from plant juices and plant extracts, E. SCHULZE (*Landw. Vers. Stat., 59 (1904), No. 5-6, pp. 344-354*).—Methods and reagents are described which the author has found valuable in studying the organic bases of plants.

Gravimetric determination of phosphoric acid, J. SEBELIEN (*Pharmacia, 1904, No. 7, pp. 1-10*).—A discussion of the different gravimetric methods for the determination of phosphoric acid, with special reference to the methods proposed by Woy (E. S. R., 9, p. 321) and von Lorenz (E. S. R., 13, p. 14), both of which the author finds promising, especially the former method.—F. W. WOLL.

Estimation of potassium, D. SIDERSKY (*Ann. Chim. Analyt., 9 (1904), pp. 207-209; abs. in Jour. Chem. Soc. [London], 86 (1904), No. 502, II, p. 589*).—For technical purposes Fresenius's method is recommended, although it is claimed that Schloesing's perchlorate method also gives trustworthy results. It is stated that in the first method 1 gm. of the platinum double salt represents 0.3056 gm. of potassium chlorid, in the second 1 gm. of perchlorate represents 0.5382 gm. of potassium chlorid.

The detection of corn meal in bread, D. OTTOLENGHI (*Ztschr. Untersuch. Nahr. u. Genussmtl., 8 (1904), No. 3, pp. 189-193*).—According to the author the most satisfactory method of detecting corn meal in bread is by means of tests for maisin, a

characteristic proteid of maize discovered by Donard and Labbé (E. S. R., 14, p. 738). The technique of the method proposed is described.

The determination of boric acid in cider, fruits, etc., A. H. ALLEN and A. R. TANKARD (*Analyst, 29 (1904), No. 343, pp. 301–304*).—To learn something of the natural occurrence of borax, examinations of a number of samples of apples and other fruits, cider, and apple juice were made. The amounts of boric acid in the fruits examined ranged from 0.004 per cent in grapes to 0.016 per cent in quince and one of the pears examined. In cider and apple juice the range was from 0.004 gm. to 0.017 gm. per 100 cc. The analytical methods followed are described.

Further contributions to the Gottlieb and Adams methods of fat determination, L. F. ROSENGREN, (*Nord. Mejeri Tidn., 19 (1904), No. 22, pp. 291, 292*).—The author corroborates Barthel's findings as to the comparative results obtained by the two methods of determinations of fat in skim milk, and shows that the insoluble substance obtained in the Gottlieb method is not identical with Storch's membrane slime, but is essentially lecithin. The higher results obtained in the analysis of milk by the Gottlieb method are not, therefore, explained on the hypothesis that a portion of the membrane slime is dissolved by the ether-benzine mixture and renders the fat obtained in the Gottlieb method impure, as suggested by Storch.—F. W. WOLL.

On the determination of fat in cheese, M. SIEGFELD (*Milch Ztg., 33 (1904), No. 19, pp. 289–292*).—Five different methods of determining the percentage of fat in full-cream and skim-milk cheese were compared—extraction with anhydrous ether, the Schmidt-Bondzynski, substitution of sulphuric for hydrochloric acid in the Schmidt-Bondzynski method, the Gottlieb, and Gerber methods. Several of the methods were modified to some extent by the author in making the analyses.

The results of the comparative analyses indicate that duplicate determinations by any one of the methods, as well as the average results obtained by different methods, in general, agree quite well. In the case of skim-milk cheese the extraction method gave too low results, and difficulty was sometimes experienced with both the Gerber and the Gottlieb methods. The Schmidt-Bondzynski HCl method modified by Ratzlaff[a] is preferred by the author.—F. W. WOLL.

Micro-chemical detection of sugars by means of phenylhydrazin acetate, E. SENFT (*Monatsh. Chem., 25 (1904), pp. 397–421; abs. in Jour. Chem. Soc. [London], 86 (1904), No. 502, II, p. 595*).—According to the author, sugars are best detected under the microscope in the form of their osazones, prepared according to the method described by the adding to phenylhydrazin acetate in glyceron, the sugar it is desired to test.

The hydrolytic products of sugar-cane fiber, C. A. BROWNE, Jr. (*Jour. Amer. Chem. Soc., 26 (1904), No. 10, pp. 1221–1235, pl. 1*).—The fact that sugar-cane bagasse is being utilized for paper making has led to renewed interest in the chemical composition of the sugar-cane fiber. The author notes that the tissues of the sugar cane resemble very closely those of maize, sorghum, and many other monocotyledonous plants. The different layers of the cane were separated, analyzed, and extended studies made of the carbohydrates of sugar-cane fiber.

The author concludes that when pure this fiber (excluding protein, fat, ash, etc.) consists approximately of cellulose, including oxycellulose 55 per cent, xylan 20 per cent, araban 4 per cent, lignin 15 per cent, and acetic acid 6 per cent. The fiber of sugar cane, it is pointed out, resembles very closely in composition the pithy stalks of maize, both being allied to the cereal straws. The formation of pentosans physiologically from modifications of cellulose, and related topics are spoken of.

"The various substances into which woody fiber may be resolved by hydrolysis have led many to believe that we are dealing with more or less of a mechanical mixture—a substratum of cellulose overlaid with 'incrusting substances.' This view,

[a] Milch Ztg., 32 (1903), No. 5, p. 65.

however, is no longer tenable. The cellulose, pentosans, lignin, and acetic acid obtained from cane fiber are all hydration products, which in the parent substances, are intimately combined. While, therefore, a study of the groups split off by hydrolysis is our chiefest aid in investigating the problems of constitution, the mistake must not be committed of regarding the products obtained by chemical treatment as absolutely identical with fiber constituents."

The origin and formation of honey, and its relation to the polariscope, W. A. Selser (*Amer. Jour. Pharm., 76 (1904), No. 6, pp. 267–271*).—The formation of honey by the bee is discussed and the results are reported of studies with the polariscope of a number of samples of honey gathered in the western and southwestern United States with the object of securing data for the detection of adulterated honey.

Determining the alcohol content of wine by means of its flashing point, P. N. Raikow and P. Schtarbanow (*Chem. Ztg., 28 (1904), No. 76, pp. 886–888*).—The author studied the flashing point of wine as a method for determining its alcohol content and compared this with other methods. The discrepancies observed were attributed to the presence of volatile compounds other than alcohol. Suggestions are given regarding the interpretation of the results obtained by the flashing-point method.

The fatty oil of strawberries, I. Aparin (*Zhur. Russ. Fiz. Khim. Obshch., 36 (1904), pp. 581–596; abs. in Jour. Chem. Soc. [London], 86 (1904), No. 502, II, p. 583*).—According to the author's determinations, strawberry oil had a specific gravity of 0.9345 at 15° and normal atmospheric pressure; at 25° it was 1.4790. The saponification number was 193.7; the acid number 6.41; the Reichert-Meissl number 2.1; Hubl's iodin number 180.3. The oil contained 88.2 per cent insoluble fatty acids having an iodin number of 192.3. Linoleic acid, about 81 per cent, linolenic acid, about 10.5 per cent, and oleic acid were the principal acids present.

Investigations of linseed oil and methods of protection of wood and iron, 1899–1903 (*Copenhagen, 1903, pp. 107*).—A preliminary report, issued by the Danish State Technical Testing Laboratory, on methods of examination of linseed oil, and on the value of methods of preservation of wood and iron by means of coal tar, oil varnishes, and paints of different kinds.—F. W. WOLL.

Extract from the flowers of iris as a sensitive indicator, A. Ossendovski (*Zhur. Russ. Fiz. Khim. Obshch., 35 (1903), p. 845; abs. in Zhur. Opuitn. Agron. [Jour. Expt. Landw.], 5 (1904), No. 1, p. 132*).—The author tested for its qualities as an indicator an extract prepared from the petals of the Japanese iris, and found that it affords the possibility of distinguishing mineral from organic acids, and mineral from organic alkalis. Besides, the change of the color in neutralization takes place gradually, passing a series of clearly distinguishable tones, which render this extract especially serviceable.—P. FIREMAN.

The occurrence of aluminium in vegetable products, animal products, and natural waters, C. F. Langworthy and P. T. Austen (*New York: John Wiley & Sons; London: Chapman & Hall, Ltd., 1904, pp. V + 168*).—"The material included in this contribution to the bibliography of aluminium deals only with the occurrence of this element in vegetable products, animal products, natural waters, and a few miscellaneous materials, such as edible earths. The general purpose has been to include only reference to such articles as report separate determinations of aluminium or some of its salts, and to omit the very large number in which iron and aluminium are reported together."

The brief notes accompanying the references give the percentages of aluminium reported in the different cases.

"No attempt has been made to comment on the value of individual analyses cited, as the object of the bibliography was the collection of data rather than the critical examination of them." The bibliography contains 671 references to reports on the

occurrence of aluminium in the various products named. The use of the book is facilitated by a detailed index.

On the presence of normal formaldehyde in the products of combustion and in smoke, A. TRILLAT (*Compt. Rend. Acad. Sci. Paris, 138 (1904), No. 25, pp. 1613–1615*).

The spectro-photometric determination of small quantities of carbon monoxid in the air, L. DE SAINT-MARTIN (*Compt. Rend. Acad. Sci. Paris, 139 (1904), No. 1, pp. 46–49, fig. 1*).

An evaporimeter, A. MITSCHERLICH (*Landw. Vers. Stat., 60 (1904), p. 63*).—This consists of a clay cell such as is used in electric batteries kept saturated from within. The advantage claimed for this apparatus is that it is not affected by rain and other weather conditions and so may be used in the open.

BOTANY.

Report of the botanist, B. D. HALSTED and J. A. KELSEY (*New Jersey Stas. Rpt. 1903, pp. 461–554, pls. 13*).—A considerable portion of the report of the botanist is taken up with experiments in plant breeding, which are noted elsewhere (p. 464). A brief account is given of experiments with fungicides, which has already been noted (E. S. R., 15, p. 274).

The distribution of asparagus rust throughout the United States, as indicated by correspondence with botanists of the different experiment stations, is shown. Examination of the plats of asparagus cultivated at the station showed the presence of the rust during the late autumn and at no time was it very severe in its attack. An inspection of the plants in November showed only traces of the disease upon the varieties Palmetto and Argenteuil, while other varieties were affected to an extent of about 10 per cent. This is quite a reduction in the amount of injury over the previous seasons, when from 20 to 75 per cent of the plants were injured.

Studies on the powdery mildews of the United States are given, showing their distribution, classification, development, etc., and special notes are given on the powdery mildews affecting the various economic plants. Remedies for their control are noted, and attention called to a statement in a previous publication (E. S. R., 15, p. 274) on the value of kerosene emulsion for the prevention of powdery mildews on hothouse-grown plants.

In an experiment in which plants were sprayed at intervals of about 1 week with water in which copper filings had been kept for some time, the sprayed plants were less attacked by the powdery mildew at the end of the experiment than check plants grown under otherwise similar conditions. The paper on the mildews concludes with a list of the species and their distribution throughout the United States, together with their host plants and a bibliography of publications relating to them.

In continuation of the previous report (E. S. R., 15, p. 161), the authors report on fungi as related to weather, the season covered by the report having been one especially suited to the development of certain fungi. In addition to mentioning the occurrence of certain diseases, notes are given on the mildew of Lima beans, the rotting of potatoes, tomato diseases, diseases of the pear orchard, etc., and the report concludes with a record of temperatures for the past 15 years.

On the change of the albuminoid substances in moldy fodders, M. F. IVANOV (*Collection Works Kharkov Vet. Inst., 6, pp. 1–85; abs. in Zhur. Opuitn. Agron. [Jour. Expt. Landw.], 5 (1904), No. 2, pp. 263, 264*).—This is a series of investigations carried on under the direction of Prof. S. A. Ivanov, on the effect produced on fodders by various molds.

In the first series of experiments *Penicillium glaucum* and an unknown brown mold were grown on flour obtained from Hungarian and Zhelanni oats. When the molds were grown on the Hungarian oats, which have a low nitrogen content, nitrogen was

assimilated from the air. In the molding of the Zhelanni oats, with a higher nitrogen content, a decrease was noted in the total nitrogen. In general, the total nitrogen of the albuminoid substances decreased during the period of molding. At first the *P. glaucum*, growing on the Hungarian oats, resulted in a considerable increase in albuminoids, but after about 2 weeks this form of nitrogen diminished and the nitrogen of the amido acids and that precipitated by phosphotungstic acid increased. The nitrogen present in alcoholic extracts was found to increase during the entire period of moldy growth. This is held to be of great importance, as in these extracts are present poisonous substances possessing some of the properties of plant alkaloids.

In the second series of experiments *Aspergillus niger* was grown on flour obtained from carrots, turnips, and potatoes. An increase in the total nitrogen was noticed in the case of the carrots and turnips, but not of the potatoes. A considerable increase of albuminoids took place at the expense of the nitrogen of the amido acids and that precipitated by the phosphotungstic acid, the maximum taking place in about 12 days, after which the albuminoids were destroyed and the other nitrogenous compounds augmented. The alcoholic extract from molded tubers gradually decreased. The artificial addition of glucose and starch to molding tubers would not affect the total nitrogen.

The author undertook the study of the products of decomposition, and found among the decomposition products of albuminoids under the development of *A. niger* on the seeds of yellow lupines an inconsiderable quantity of tyrosin and larger quantities of leucin and ammonia, the latter combined with oxalic acid. Tests for arginin and histidin gave negative results.—P. FIREMAN.

Notes on the mycorrhiza of forest trees and their symbiosis with roots, G. F. C. SARAUW (*Rev. Mycol., 25 (1903), No. 100, pp. 157–172; 26 (1904), No. 101, pp. 1–19, pl. 1; abs. in Bot. Centbl., 95 (1904), Nos. 6–7, pp. 159, 160; 20, pp. 539, 540*).—In continuation of a previous paper (E. S. R., 4, p. 693), the author summarizes his investigations and incorporates some recent information regarding the occurrence and function of mycorrhiza on the roots of forest trees and shrubs.

Forest trees are divided into 3 categories based upon the nature of their mycorrhiza—those having intracellular mycelium, such as cedrus, box, elms, and maples; intercellular mycelium, and an external mycelial sheath, as spruce, fir, larch, pines, oaks, hazels, birches, willows, and possibly linden; and those having neither internal nor external mycelium, as the ash, horse-chestnut, elder, etc. The common juniper is said to have an intracellular mycelium in the second group, but is without the mycelial sheath.

In the second part of the contribution the author gives a report on the biological importance of mycorrhiza and a study of the biology of the fungus symbiont. The opinions of Frank and others regarding the importance of mycorrhiza are reviewed, and it is claimed that Frank's experiments with forest seed in sterilized soil lacked some important factors of control. The present author holds that humus in the soil is necessary only in determining the abundance of mycorrhiza, and cites the infrequence of such growths in garden soils often rich in humus, while mycorrhiza may be and often is abundant in trees growing in shifting sands.

The presence of mycorrhiza in very sandy soils is said to be due to dead leaves which carry the different fungi capable of infecting tree roots. The question of nitrogen absorption through the mycorrhiza and roots the author claims has not been proved. It is claimed that trees have become accustomed to symbiosis with fungi, but it is held to be neither necessary nor advantageous to them. The infection takes place through vegetable débris carrying the fungi and the fungi live a sort of saprophytic life in the soil. From a limited study of the various organisms, the author claims to have recognized conidial types corresponding to Cladosporium and Helminthosporium, and he believes that the fungi which produce mycorrhiza belong

to the group Spheriaceæ. It is considered doubtful whether truffles, puffballs, etc., can form mycorrhiza.

The decomposition of dead leaves in the forest, E. HENRY (*Ann. Sci. Agron., 2. ser., 1902-3, II, No. 3, pp. 328-333*).—The author found that in the case of leaves placed in zinc boxes, or brought in contact with zinc salts, the action of the bacteria causing decomposition of the leaves was greatly checked. When compared with the same leaves under normal conditions the decomposition was reduced about half during the first year. In some cases only about 15 per cent decomposition took place within a year. Leaves of some species were found to decompose much more rapidly than others, and the leaves of the hornbeam, although much less coreaceous and containing much less tannin than oak leaves, are not decomposed as rapidly as the oak leaves when submitted to normal conditions.

Fixation of the atmospheric nitrogen by dead leaves in forests, E. HENRY (*Ann. Sci. Agron., 2. ser., 1902-3, II, Nos. 2, pp. 313-320; 3, pp. 321-327*).—The results of some recent experiments on the fixation of nitrogen by leaves are given, and the author concludes that dead leaves of the oak, beech, hornbeam, poplar, Austrian pine, and spruce are able, either alone or mixed with soil, when in a moist substratum, to fix considerable portions of nitrogen from the air. Leaves of pine, beech, and spruce placed in pure sand or in a poor dry soil were either unable to take up any atmospheric nitrogen to enrich the soil, as in the case of the beech, or to assimilate a very slight amount, as in the case of the leaves of pine and spruce. In none of his experiments was there any loss of nitrogen.

The enzym-secreting cells in seedlings of maize and dates, H. S. REED (*Ann. Bot., 18 (1904), No. 70, pp. 267-287, pl. 1*).—In continuation of the preliminary account previously noted (E. S. R., 15, p. 752), the author has studied the enzym-secreting cells of seedlings of *Zea mais* and *Phœnix dactylifera*. It was found that in the resting condition the secreting cells of both maize and dates are crowded with relatively small proteid granules. As secretion begins these granules gradually disappear. In maize the disappearance coincides closely with the consumption of the endosperm. In the date, however, the granules disappear long before the endosperm is dissolved.

The chromatin of the nuclei is small in amount at the beginning of secretion and increases as germination progresses. The nucleolus diminishes with the progression of germination. These changes are more noticeable in the case of maize than in the date. There is no evidence that solid matter is extruded from the nucleus. At the end of secretory activity the protoplasm of the secreting cells breaks down and the products of disintegration disappear from sight.

Studies on evaporation by purslane, E. B. WATSON (*Wallaces' Farmer, 29 (1904), No. 42, p. 1269*).—The results of experiments carried on at the Iowa Agricultural College, in which the effect of the growth of purslane on the temperature and moisture of the soil is shown. The weed grew in great abundance and practically covered small plats in the nursery and these were studied, comparisons being made with adjacent plats which were under cultivation. The effect of the purslane on the temperature of the soil is shown by the following table:

Table showing effect of purslane on soil temperature.

Depth.	Cultivated plat.	Purslane plat.	In favor purslane.
	Degrees F.	*Degrees F.*	*Degrees F.*
Surface	104.0	79.2	24.8
One and one-half inches	82.4	72.0	10.4
Three inches	77.7	68.9	8.8

From this table it is shown that while the surface soil of the cultivated plat had the highest temperature, the difference for the lower strata was less than for the surface. The moisture determinations are shown in the following table:

Table showing percentage of moisture in the 2 plats.

Depth.	Hoed plat.	Purslane plat.	In favor of hoed.
	Per cent.	*Per cent.*	*Per cent.*
Surface soil, first 7 inches	23.7	18.5	5.2
Subsurface, 7 to 21 inches	22.3	19.5	2.8

The results obtained in this determination show that when compared with the table showing the temperature, in spite of the fact of the purslane-covered plats being cooler, there was a decided decrease in the amount of moisture in the soil and subsoil. The author has calculated the amount of water evaporated by the purslane over that evaporated from the cultivated soil and found that it amounted to almost exactly one inch during the time of the experiment, which was limited to 12 days.

Some metabolism products of peas attacked by Aspergillus niger, J. Kosjatschenko (*Zhur. Opuitn. Agron.* [*Jour. Expt. Landw.*], *1903, No. 4, pp. 439–450; abs. in Bot. Centbl., 95 (1904), No. 22, p. 590*).—The author has investigated the metabolism products of proteids in peas when attacked by *Aspergillus niger*. After 64 days' cultivation of the fungus on ground pea meal, the author found present tyrosin, leucin, ammonia, histidin, arginin, and lysin.

FERMENTATION—BACTERIOLOGY.

Experiments on the transformation and fixation of nitrogen by bacteria, J. G. Lipman (*New Jersey Stas. Rpt. 1903, pp. 217–285, pls. 2*).—A report is given of investigations made to determine the behavior of bacterial mixtures, as they are found in fresh soils, in nitrogen-rich and in nitrogen-poor solutions; to determine what gains or losses of nitrogen may occur, and to study isolation in pure culture and physiological and morphological characteristics of nitrogen-fixing bacteria. Considerable attention is given to methods of isolation, and the conditions under which fixation by atmospheric nitrogen may be accomplished in the laboratory. A number of nitrogen-fixing organisms were isolated in pure cultures and the results of studies made with them are given in detail.

The author isolated a species of Azotobacter from soil which showed marked capabilities of assimilation of nitrogen. These organisms were found to occur abundantly in certain soils of the State, and the organism as shown by its cultural characteristics is described. The name *A. vinelandii* has been given it. In connection with studies of this organism others were isolated, especially species of Bacillus, some of which seem to be closely associated with the Azotobacter. It is believed that one species, *Bacillus 30*, exists in symbiosis with *A. vinelandii*, and inoculation experiments showed a decided increase in the amount of nitrogen fixed where the two organisms are used in conjunction. Each species was found capable of assimilating and fixing atmospheric nitrogen when grown separately in culture media, but when grown together the amount of nitrogen fixed was increased many-fold.

A contribution to the study of fermentation, I, E. H. Twight and C. S. Ash (*California Sta. Bul. 159, pp. 26, figs. 16*).—An account is given of cooperative investigations between the California Station and the California Wine Association, in which a study was made of the influence of temperature and of acidity of must on fermentation, the influence of selected cultivated yeasts as compared with the natural or wild yeasts, and the comparative value of wines derived from these experiments.

The observations recorded were made on 360 fermentations in tanks of 5,000 gal. capacity each, making a total of 1,250,000 gal. of wine, which, it is believed, will put the work on a practical basis.

It was found in the fermentation of wine that the temperature varied from 60 to 105° F., with an optimum temperature of about 85° F. When wine was fermented at a much higher temperature the amount of sugar reduced was depreciated and the amount of acetic, lactic, and other acids increased, with a depreciation in the amount of alcohol. Fermentation at 85° F. or lower results in a reduced amount of volatile acids and albuminoids, and an increase in the percentage of alcohol and dryness. Experiments with the cultivated yeasts showed that fermentation was more regular and more rapid with the cultivated forms than with those naturally occurring on the fruit. The period of fermentation was about the same for both, and the temperature at which the best fermentation took place was the same.

Investigations were carried on to determine the effect of the addition of sulphurous acid or sulphites to white wine, the theory upon which their use was based being that the chemical will stop the natural fermentation, leaving a comparatively clean must to be drawn off. This must is then inoculated with pure cultivated yeasts which have been developed so as to produce fermentation in the presence of a considerable percentage of sulphurous acid. So far as the investigations have been carried the results obtained are believed to be very satisfactory.

METEOROLOGY—CLIMATOLOGY.

Meteorological chart of the Great Lakes, A. J. Henry and N. B. Conger (*U. S. Dept. Agr., Weather Bureau, Meteorological Chart of the Great Lakes, 1904, No. 1, pp. 30, pls. 5, figs. 2*).—This is a summary of observations on the meteorological conditions of the winter of 1903–4 in the lake region, with notes on the opening of the navigation season of 1904, ice during the winter of 1903–4 at different points on the Great Lakes, display of storm signals on the lakes, and lists of observation and storm-warning stations.

Meteorological observations, J. E. Ostrander and G. W. Patch (*Massachusetts Sta. Met. Buls. 187, 188, 189, pp. 4 each*).—Summaries of observations on pressure, temperature, humidity, precipitation, wind, sunshine, cloudiness, and casual phenomena during July, August, and September, 1904. The data are briefly discussed in general notes on the weather of each month.

Meteorological and magnetic observations at the observatory of the College of Belen, Havana, 1903, L. Gangioti (*Observaciones meteorologicas y magneticas hechas en el observatorio del Colegio de Belen, Habana, 1903. Havana: Colegio de Belen, 1904, pp. 74, charts 3*).—Detailed records and summaries of observations on pressure, temperature, tension of aqueous vapor, humidity, wind, evaporation, cloudiness, and rainfall are given for each day and for different hours of the day for each month of the year 1903. Casual phenomena and magnetic observations are also noted. The mean atmospheric pressure for the year was 762.19 mm. (29.725 in.), maximum 769.84 mm. (30.024 in.), minimum 755.73 mm. (29.473 in.); the mean temperature (shade) 24.8° C., maximum 32.7 (August 22), minimum 12.6 (December 4); the average relative humidity was 74.2; the total rainfall 1,311.9 mm. (51.06 in.).

Meteorology of the spring of 1904 (*Bul. Dir. Agr. et Com.* [*Tunis*], *9* (*1904*), *No. 32, pp. 464–475*).—A summary of observations at different places in Tunis on atmospheric pressure, temperature, cloudiness, etc., for the months of March, April, and May, 1904.

Invariability of our winter climate, W. B. Stockman (*U. S. Dept. Agr., Weather Bureau Doc. 312, pp. 5; reprint from Mo. Weather Rev., 32* (*1904*), *No. 5, pp. 224–226*).—Temperature data "covering a considerable period of years at a number of selected

stations, so distributed as to show the general conditions obtaining over the country generally east of the Mississippi Valley" are compiled and discussed. The places for which data are given are Fort Snelling, Minn.; Fort Leavenworth, Kans.; New Orleans, La.; Chicago, Ill.; Cincinnati and Cleveland, Ohio; New Bedford, Mass.; Washington, D. C.; and Charleston, S. C.; and the period covered runs back to 1854. "From a study of the departures given during the last past 50 years it will be seen that the contention that the winters of recent years are less rigorous than those of former years, at least so far as temperature is concerned, is not well founded."

Climate of Missouri (*The State of Missouri. Columbia: Missouri Commission to Louisiana Purchase Exposition, 1904, pp. 59–62, figs. 8*).—The more important climatic characteristics of the State are shown on maps and briefly discussed.

Rainfall in the agricultural districts, E. L. Fowles (*Queensland Agr. Jour., 15 (1904), No. 1, p. 517*).—A table shows the total rainfall for each month from May, 1903, to May, 1904, inclusive, in the agricultural districts of Queensland.

Weather forecasts from the humming of wires, R. DeC. Ward (*Science, n. ser., 20 (1904), No. 512, p. 540*).—A brief reference to a report of a study by F. Bock given in the August number of *Das Wetter*, in which certain rules for forecasting weather conditions based on observations on the humming of telegraph and telephone wires are laid down.

Fertility and frost, U. P. Hedrick (*Michigan Farmer, 46 (1904), No. 20, p. 358*).—Observations are recorded which go to show "that vegetation on a well-fertilized soil is better able to withstand frost than is that on a poor soil."

Destructive floods in the United States in 1903, E. C. Murphy (*U. S. Geol. Survey, Water Supply and Irrig. Paper No. 96, pp. 81, pls. 13, figs. 2*).

SOILS.

Geology of Oktibbeha County, Mississippi, W. N. Logan (*Bul. Mississippi Agr. and Mech. College, 1 (1904), No. 2, pp. 67, figs. 12, map 1*).—This survey, which was conducted under the auspices of the Agricultural and Mechanical College of Mississippi, includes studies of geography, hydrography, topography, physiography, archeology, and geology, with detailed discussions of the characteristic formations and economic deposits (sand, brick material, cement material, road metal, and phosphatic marl), and special articles on soils by W. L. Hutchinson, W. R. Perkins, and H. S. Chilton, forage plants and grasses by G. W. Herrick, and forestry and trucking lands by A. B. McKay. The chapter on soils describes the characteristic types, with physical and chemical analyses, and discusses their fertilizer requirements.

The relation of smelter smoke to Utah agriculture, J. A. Widtsoe (*Utah Sta. Bul. 88, pp. 147–179*).—This bulletin records the results of a careful and detailed study of the nature and extent of damage done to trees, orchards, crops, live stock, and soils by the smoke from copper smelters in or near the towns of Murray and Bingham Junction, some 5 to 7 miles south of Salt Lake City, Utah, as well as of the substances emitted by the smelters. The most noteworthy substance found in the smelter smoke was sulphur dioxid, which varied from 59 to 93 parts per 10,000 of air, according to the distance from the smelter ($1\frac{1}{4}$ to $\frac{1}{2}$ mile).

"The amount of solid particles carried by the air which had passed over the smelter chimneys was so small that it could not be investigated by any ordinary methods of analysis. To collect large quantities of the flue dust, special dust collectors were contrived and set up in various places near the smelters . . . Chemical examination showed these dust samples to contain a large quantity of iron, some copper, and traces of arsenic. In addition were numerous particles of soil dust. That this dust really came from the smelters was proved by the large quantity of magnetic particles found in the samples."

Summarizing the results, it is stated that "when the wind causes the smoke to

beat upon a field for a considerable length of time, it tends to injure the crops severely and thus to diminish their yields. It tends to injure animals that are right in the line of the prevailing winds, and therefore are compelled to breathe the smelter smoke in the air. It may occasionally poison pools of standing water, when the washing of rains and melting snows cause a concentration of the flue dust in low-lying places . . . It does not injure equally all land within any given radius. The injured fields are those in the paths of the prevailing winds. It does not injure the fertility of the soils of the district. It does not affect materially the feeding value of crops grown in the district."

Practical suggestions to farmers as to how to manage lands subject to injury by smelter smoke are made.

A new centrifugal soil elutriator, P. A. Yoder (*Utah Sta. Bul. 89, pp. 47, figs. 13*).—This bulletin refers briefly to the more important methods and apparatus for mechanical analysis which have been heretofore proposed, pointing out some of the disadvantages which most of them possess, and describes an apparatus combining the fundamental principles of the centrifugal and elutriator methods, which, it is claimed, enables the analyst "to make a good separation in a comparatively short time, using a relatively small volume of water, and securing at once each grade of particles except the fine clay, in a minimum of water, ready for drying and weighing."

In the apparatus described a special form of current elutriator is placed in suitable sockets in a centrifugal machine, and carefully balanced by means of an adjustable counterpoise. The muddy water resulting from the shaking up of a weighed sample of soil is run in a uniform stream through the machine, and by regulating the velocity of this stream or the rotary speed of the machine, it is possible to control the grade of particles which are separated.

A section of the centrifugal machine, with elutriator bottle and counterpoise in position, is shown in figure 6. An enlarged section of the elutriator bottle is shown in figure 7. This bottle is so designed as regards shape that a uniform force is exerted on the suspended soil particle in all parts of the bottle where separation takes place. By making the outline of the bottle a parabolic curve, with the diameter increasing as the axis of the machine is approached, it was found possible to maintain a uniform ratio between centrifugal force and the force exerted by the stream of water.

The machine is found most useful for separating particles less than 0.03 mm. in diameter, this fine material being most conveniently separated from the original sample of soil by gravity elutriation. The elutriator bottle receives the water containing the suspended soil through the funnel F, the axis of which coincides with the axis of the centrifugal machine. From this funnel the water is carried to the bottom of the bottle by means of a small tube. The overflow escapes through a larger tube concentric with this smaller tube through the neck of the elutriator bottle and is carried by a side tube T to a circular spray collector above. From this collector a delivery tube drains the liquid into a beaker.

The size of the particles which pass out of the machine suspended in water depends both upon the velocity of the stream of water and upon the speed of the machine. A uniform flow of the water containing the suspended soil particles is secured by allowing the water to flow from a closed funnel-shaped vessel only as fast as air is admitted from a larger closed bottle serving as an air chamber into which water flows from the Mariotte bottle placed above through a valve which can be regulated at will.

By a series of experiments the relations between the speed of the machine and the velocity of the current on the one hand and the size of the soil particles on the other were carefully worked out. From the data obtained diagrams are plotted and formulas are deduced for definitely determining these relations.

In the actual operation of the machine 10 gm. of soil is thoroughly disintegrated

by shaking or boiling for half a day or more. The soil is then rinsed into the narrower of a series of gravity elutriators (of the Schöne type), while a slow stream of water flows through to prevent the sediment from choking the tube. After all the soil has been transferred the stream is turned on to a velocity of nearly 37.09 cc. per minute. When the larger part of the fine material has been removed the current is turned on to the full strength of 37.09 cc. per minute required to separate particles of 0.0316 to 0.1 mm. in diameter. The overflow from the narrower elutriator passes

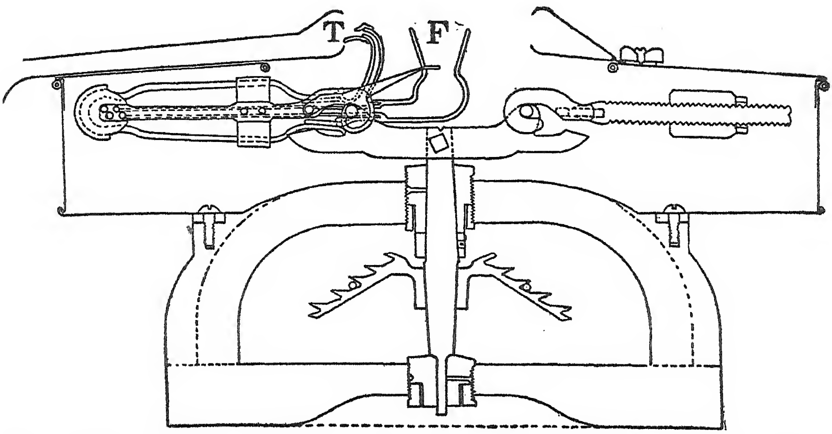

FIG. 6.—Yoder's centrifugal elutriator; vertical section. (From U. S. Dept. of Agr., Bureau of Soils Bul. 24.)

into the wider elutriator and thence into a beaker for further use in the centrifugal elutriator.

The first 300 to 600 cc. of the muddy water from the gravity elutriator containing nearly all the fine clay is collected, and while the gravity elutriation is being completed this water is run through the centrifugal elutriator at the speeds required for the separation of the finest grade (0.001 mm. particles), namely, with a current of 43.75 cc. per minute and a centrifuge speed of 1,888 revolutions per minute. The muddy water thus obtained contains most of the fine clay, a small portion being carried down to the bottom of the bottle with the coarser sediment. This sediment is

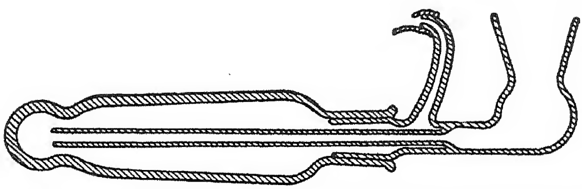

FIG. 7.—Centrifugal elutriator bottle; longitudinal section. (From U. S. Dept. of Agr., Bureau of Soils Bul. 24.)

thoroughly shaken up with more of the muddy water from the gravity elutriator and all is put through the machine at such a speed of centrifuge and water flow as will give a separation of the 0.01 mm. particles, namely, 91.46 cc. and 404 revolutions per minute.

When the muddy water has all passed through, followed by a little rinsing water, the machine is stopped. The sediment will be found to be so firmly imbedded in the bottom of the elutriator bottle that the muddy water can be poured off from it. The sediment is then shaken up in 150 to 200 cc. of clear water and run through the

machine at the same speed a second time. Thus freed from the finer grades it is transferred with a little clear water to a weighed dish and is dried and weighed as coarse silt. The muddy water from this elutriation is run through the machine at such speed of centrifuge and water current as will effect the separation of the next size of particles, 0.00316 mm., namely, 95.73 cc. and 1,148 revolutions per minute. The sediment is shaken up once and run through at the same speed, then collected and weighed as medium silt.

In a similar manner separation is made at the required speed of the fine silt, 0.001 mm. particles. The material remaining in suspension at the end of the process is precipitated by the addition of a solution of sodium chlorid (50 cc. of saturated brine to 1 liter of the water containing suspended material). After standing 4 hours, or better over night, the water is siphoned off, the sediment collected, dried, and weighed, and the salt in it determined volumetrically with silver nitrate solution (1 cc. equivalent to 0.01 gm. NaCl).

From the results of a series of tests of the apparatus under a variety of conditions the conclusion is drawn that "the advantages which the writer thinks should commend this new machine for the mechanical analysis of soils are the rapidity with which separations can be completed and the small sizes of grains which can be separated and estimated. Very great accuracy is not claimed for the method, and indeed such can hardly be claimed for any method yet proposed. It is the opinion of the writer that very great refinement in the determinations of the several grades of soil particles has but little value above that in determinations which are accurate within one or two per cent."

The effect of soil sterilization upon the development of plants, C. Schulze (*Jahresber. Ver. Vertreter Angew. Bot., 1 (1903), pp. 37–44; abs. in Bot. Centbl., 95 (1904), No. 22, p. 586*).—On account of the fact that many experiments are carried on in soil sterilized by heat, the author has investigated the effect of high temperatures on the soil compounds. It was found that a sterilizing temperature affects the decomposition products of some soils in a way that is detrimental to plant growth, in some of the experiments the plants proving exceedingly sensitive to the changes produced. On the other hand, sterilization of soil by heat results in the liberation of soil compounds, especially the insoluble nitrogen compounds, resulting in a greatly increased growth of the plant when compared with plants grown in normal soils.

An artificial root for inducing capillary movement of soil moisture, L. J. Briggs and A. G. McCall (*Science, n. ser., 20 (1904), No. 513, pp. 566–569*).—The apparatus here described was devised for the purpose of studying the rate at which a plant is able to secure water from a soil. It consists of a Pasteur-Chamberland filter tube connected by means of a short piece of lead tubing to a 2-liter bottle exhausted to pressure equal to the vapor pressure of water. The filter tube is buried in the soil which is to be studied, but preparatory to doing this "a core of soil is removed by means of a tube, the external diameter of which is equal to that of the smaller end of the porcelain tube. The filter tube is slightly conical in form, so that when it is forced into this hole a good capillary connection is established between the walls of the tube and the soil."

In the investigations reported "the apparatus was usually allowed to stand for about 24 hours, when the exhausted bottle was detached and the water which had been drawn into the apparatus removed and measured. The porcelain tube was not disturbed in removing the water, which was drawn into a small flask by suction through a fine tube extending to the bottom of the porcelain tube. The apparatus was then immediately put together again and exhausted by means of an aspirator.

"The water thus removed not only represents the amount of water which the soil has supplied to the tube during the preceding period of 24 hours, but it appears to be identical in concentration and composition with the soil solution from which the plant obtains its food. Therefore, the determination of the amount and composition

of its soluble material gives us at once the concentration and composition of the soil solution. The apparatus thus provides a simple means of studying the changes which take place in the solution from which plants obtain their mineral food. . . .

"The [average] rate of translocation of the soil moisture into the tube, at the beginning of the experiment [June 7–8], after a heavy rain, was 8.9 gm. per hour. It fell steadily during the next two weeks to about 1 gm. per hour. Heavy rains on July 1 brought the rate up to an average of 13.7 gm. per hour for the 24-hour period, after which it fell to 1.5 gm. per hour on July 7, and so on."

It is claimed that the studies made with this apparatus indicate that it provides "(1) a means of determining the rate at which water can be supplied by a soil to an artificial root, by means of which a capillary pull is exerted upon the soil moisture of any desired magnitude up to 1 kg. per square centimeter. This makes possible the comparison of rates of capillary movement in different soils under field conditions.

"(2) A simple method of removing a portion of soil moisture with the dissolved substances which it contains, thereby enabling a study of the concentration and composition of the soil solution under different field conditions.

"The apparatus has the disadvantage of being able to remove water from the soil only when the latter is comparatively moist; in other words, it fails to give information regarding the rate of movement of soil moisture during conditions approximating a drought. Experiments are now in progress with a view to extending the range of the apparatus."

An artificial root for inducing capillary movement of soil moisture, F. H. King (*Science, n. ser., 20 (1904), No. 516, pp. 680, 681*).—A note on the above article, which raises the question whether the evidence presented by the author "is sufficiently conclusive to warrant the views there expressed, or [whether] they have succeeded in devising an artificial root which, in any essential way, can be said to represent or measure the natural movement of soil moisture in a soil toward an active root."

It is pointed out that "even if the author's conclusions be not correct regarding the cause of the flow of water in the experiment, the line of investigation is important in that it has provided a means of securing water from field soils, perhaps, in a somewhat more concentrated condition than occurs in natural drainage, and permits the sample to be taken where its history may be very definitely known; and it is to be hoped that they and others will apply the method in investigating the character of soil extracts thus obtained." It is regarded as extremely doubtful, however, whether "either the concentration or the composition of solutions so procured will be found to be the same as that which closely invests the soil grains or the root hairs at the same place and time."

Soil moisture studies, C. H. Kyle (*Industrialist, 30 (1904), No. 35, pp. 567–580, fig. 1*).—This article gives the results of a study of the moisture conditions during the summer of 1903 in soil under different methods of culture and crop rotation.

"The method employed in determining the amount of moisture in the soil is the gravity method. Samples of the soil of the field or plat under experiment are taken in foot sections to the depth of 6 ft., and each sample, on being removed, is placed in a separate tray and covered at once, so as to prevent loss of moisture. In order to obtain an average sample four (duplicate) samples are usually taken, at some distance apart, of each of the first 2 ft. and two samples are taken of each of the remaining 4 ft., all samples for the same foot being placed in the same tray.

"These trays are made of heavy tin, with closely fitting lids of the same material. They are 12 in. long, 4 in. wide, and 3 in. deep. Each tray has a number stamped on its two sides, one end, and the lid, so that while in the field it is only necessary to keep a record of the foot from which the sample is taken and the number of the tray in which the sample is placed. Each tray on being filled is placed in a large, galvanized-iron chest or trunk, made for the purpose. Each chest holds sixteen trays. When all of the samples are secured the chests are carried to the laboratory

and each tray is carefully wiped with a cloth and then weighed upon a torsion balance, which weighs accurately to one-tenth of a gram. After removing the lids the trays are placed in a large drying oven, and there heated for from 18 to 24 hours, or until the temperature in the oven becomes reasonably constant at about 110° C., when the weighing is repeated, and from these two weighings and the weight of the tray the per cent of moisture is figured, with the dry weight of the soil used as a basis."

The variations in the moisture content of fall-plowed, spring-plowed, and unplowed land, and in soils under various crops and crop rotation, cultivated in different ways, especially as regards depth and frequency, were studied by this method. The results are reported in detail, but are somewhat inconclusive at this stage of the investigations.

The mechanical analysis of soils, J. G. McIntosh (*Chem. News, 90 (1904), No. 2333, p. 80*).—Tests of the methods of mechanical analysis of Nobel, Schloesing, and Masure are reported to show that they give very discordant results on the same sample of soil. The author claims that "the data afforded by a mere mechanical analysis of the soil tells nothing either to the chemist or farmer."

Micro-organisms of soil and human welfare, T. J. Burrill (*Science, n. ser., 20 (1904), No. 509, pp. 426–434*).—This is the presidential address read at the Buffalo meeting of the American Microscopical Society August 24, 1904, and briefly discusses the characteristics of soil micro-organisms and their relation to rock disintegration, nitrification, and fixation of nitrogen alone or in symbiosis with leguminous plants. The dependence of soil fertility and consequently man's prosperity and welfare upon the activities of soil organisms is emphasized.

The comparative nitrifying power of soils, S. F. Ashby (*Jour. Chem. Soc. [London], 85 (1904), No. 502, pp. 1158–1170*).—This is a preliminary report on investigations made with a view to finding a trustworthy method for comparing the activity of nitrification in different soils. The method employed in the studies here reported consisted in taking a large sample of soil at a constant depth, drying and pulverizing the sample to secure uniformity, seeding a very small quantity (0.2 gm.) in a dilute sterilized culture solution of constant depth, incubating at constant temperature until nitrification had made moderate progress in the least active solution, and calculating the results as parts per hundred of total nitrogen nitrified.

The results show that the method gave reasonably concordant nitrifying power in soil from different parts of the same field, that equal seedings from the same sample had similar nitrifying power, that the loss of nitrogen by denitrification and volatilization of ammonia during incubation was minimized, that the incubation period was about 30 days, and that a comparative nitrifying power was found in the soils tested which agreed with that which might be inferred from their known history.

Some essential soil changes produced by micro-organisms, S. F. Edwards (*Michigan Sta. Bul. 218, pp. 25–30, fig. 1*).—"The object of this bulletin is to review simply and briefly the present knowledge of soil bacteriology in its relation to agriculture with a view to emphasizing the close relationship between bacteriologic principles and the common operations of tilling the soil." It explains the conditions essential to bacterial activity and describes the processes of ammonification, denitrification, nitrification, and fixation of nitrogen, as well as other changes brought about in the soil by micro-organisms.

Soil management, E. W. Hilgard (*Science, n. ser., 20 (1904), No. 514, pp. 605–608*).—A review of three papers by F. H. King, published by the author with permission of the Secretary of Agriculture, and containing reports of investigations conducted while the author was connected with the Bureau of Soils of this Department.

A contribution to the study of the culture of alkali soils, A. Guyader (*Bul. Dir. Agr. et Com. [Tunis], 9 (1904), No. 32, pp. 451–461*).—A review of literature on this subject with applications to Tunisian conditions.

FERTILIZERS.

Investigations relative to the use of nitrogenous materials, E. B. Voorhees (*New Jersey Stas. Rpt. 1903, pp. 148–184*).—This is a report of progress in a series of investigations which has been carried on by the station for several years (E. S. R., 15, p. 128). The questions studied, the methods pursued, and the data recorded are of the same character as in previous investigations. The crop used in the experiments here reported was timothy.

The relative availability of the different nitrogenous fertilizing materials experimented with during the years 1898 to 1902 is summarized in the following table:

Relative availability of nitrogen in different fertilizing materials.

	Corn, 1898.	Oats, 1899.	Oats and millet, 1899.	Oats, 1900.	Oats and corn, 1900.	Wheat, 1901.	Timothy, 1902.
	Per cent.	*Per cent.*	*Per cent.*	*Per cent.*	*Per cent.*	*Per cent.*	*Per cent.*
Nitrate of soda	100.0	100.0	100.0	100.0	100.0	100.0	100.0
Sulphate of ammonia	99.5	72.9	77.9	99.2	87.7	91.0	38.3 or 54.4
Dried blood	95.4	58.5	61.3	68.3	73.1	75.7	34.6 or 56.9
Solid manure, fresh	16.8	12.0	43.1	14.2	26.4	31.1	63.0
Solid manure, leached	37.9	12.1	46.4	9.7	22.0	24.4	56.1
Solid and liquid, fresh	49.7	58.2	88.4	40.1	51.5	30.8	47.2
Solid and liquid, leached	50.4	20.0	33.0	28.9	35.9	19.9	69.5

In these experiments the analytical study of thé nitrogen content of the crop has been supplemented by a study of the nitrogen content of the corresponding soils with a view to determining the income and outgo of nitrogen. The method of taking and treating the soil samples for the determination of nitrogen is described.

From the results obtained in these studies of the nitrogen content of the soil and of the plant the general conclusion is drawn "that the presence of soluble nitrogen compounds at the beginning of the season allows a more economical use of the soil nitrogen, and that nitrate is of greater value in this respect than any other form of nitrogen, because of its greater solubility and the greater ease, therefore, with which it diffuses through the soil."

The use of fertilizers; a review of the results of experiments with nitrate of soda, E. B. Voorhees (*New Jersey Stas. Rpt. 1903, pp. 185–214*).—A reprint of Bulletin 172 of the station (E. S. R., 16, p. 245).

Extraction and industrial treatment of Peruvian guano, E. Leplae (*Rev. Gén. Agron. [Louvain], 13 (1904), No. 7–8, pp. 289–320, figs. 13*).—The origin of the guano deposits and the history of their exploitation are briefly reviewed. The decline of the industry due to exhaustion of the deposits and a recent revival of interest in the subject due to partial renewal of the deposits and improvement of methods of handling the material are also noted.

Sulphate of ammonia in agriculture, J. Graftiau (*Le sulfate d'ammoniaque en agriculture. Antwerp: Laporte & Dosse, 1904, pp. 79*).—A summary of information regarding the value and use of sulphate of ammonia as a source of nitrogen for different soils and crops. The author believes that when sulphate of ammonia is compared with nitrate of soda under all conditions it is not possible to draw general conclusions as to the superiority of one over the other, much less to establish a formula for their relative value.

Report of analyses of commercial fertilizers for the spring and fall of 1903, W. H. Jordan, L. L. Van Slyke, and W. H. Andrews (*New York State Sta. Bul. 252, pp. 191–268*).—The results of analyses of 540 different brands of fertilizers are reported. Of these, 377 were complete fertilizers in which the total nitrogen varied from 0.14 to 8.32 per cent, averaging 2.11 per cent; the water-soluble nitrogen from

0 to 8.91 per cent, averaging 1.02 per cent; the available phosphoric acid from 0.06 to 15.50 per cent, averaging 8.50 per cent; the potash from 0.03 to 13.33 per cent, averaging 4.78 per cent. In 62 out of the 377 brands examined the potash was in the form of sulphate free from excess of chlorids. The average amounts of nitrogen, available phosphoric acid, and potash exceeded the guaranteed averages by 0.07 per cent, 0.83 per cent, and 0.23 per cent, respectively. The average retail selling price of the fertilizers was $26.60; the retail cost of the separate ingredients unmixed, $19.64.

Analyses and valuations of fertilizers, J. P. STREET, W. P. ALLEN, and V. J. CARBERRY (*New Jersey Stas. Rpt. 1903, pp. 19–75*).—This is a reprint of Bulletin 168 of the station (E. S. R., 15, p. 571) with the addition of a list of manufacturers whose goods were sampled and analyzed during 1903, data relating to the wholesale prices of fertilizing materials in New York during different months of the year 1902 and valuations for 1903, and analyses of 6 samples of fertilizers received too late to be included in Bulletin 168.

Fertilizer analyses, F. W. ROBISON (*Michigan Sta. Bul. 217, pp. 23*).—Analyses of fertilizers examined under State laws during 1904 are reported, with notes on the objects of the inspection and on the nature and use of fertilizers and manures.

Analyses of commercial fertilizers and manurial substances, C. A. GOESSMANN (*Massachusetts Sta. Bul. 100, pp. 30*).—Analyses of samples of commercial fertilizers secured in the course of the regular inspection and of miscellaneous materials sent to the station for examination, including wood ashes, lime ashes, nitrate of soda, cotton-seed meal, dried blood, high-grade sulphate of potash, carbonate of potash, sulphate of potash-magnesia, dissolved boneblack, burned bone, phosphatic slag, tankage, ground bone, dry ground fish, wool waste, mill waste, factory waste, sheep manure, liquid manure, compound fertilizers, and soils. A schedule of trade values for 1903 and 1904 is given.

FIELD CROPS.

Field experiments at Lauchstädt, W. SCHNEIDEWIND ET AL. (*Landw. Jahrb., 33 (1904), No. 2, pp. 165–250, 273–334, pls. 6*).—The fifth report of the station presenting the results obtained in 1902 and 1903. The results of previous years have been noted (E. S. R., 14, p. 852).

The average results of 6 years' experiments show that 100 kg. of barnyard manure was worth 1 mark (about $2.50 a ton), its residual effect being included in the valuation. The highest yields of beets and potatoes were obtained where the manure was applied with commercial fertilizers. The increase in the yields of roots and tubers due to the manure was greatest when the same was applied without the addition of nitrate of soda, but the highest absolute yields were obtained where the two substances were given together.

With reference to leaf production, the reverse sometimes takes place. During the seasons favoring the growth of leaves more of the nitrogen in the manure was used by the plants when applied with nitrate of soda than when applied alone. This is attributed to the fact that the nitrate in conjunction with the manure forces the plants and consequently lengthens the vegetative period, which results in a greater nitrogen consumption than where the manure is applied alone. This greater quantity of nitrogen is used in increasing the amount of foliage and does not affect the yield of the roots and tubers. For this reason moderate applications of manure with the nitrate of soda in proportion are considered most profitable. The use of about 30,000 kg. of manure per hectare is recommended for beets, and from 20,000 to 30,000 kg. for potatoes. Fresh manure was not used in these experiments, and the results given, therefore, were not influenced by the action of denitrifying bacteria.

Experiments in the preservation of barnyard manure by means of chemicals gave negative results, and the authors recommend keeping manure moist and well packed under cover, or using peat and soil to prevent deterioration.

Green manuring with peas, beans, and vetches after summer or winter barley gave good results with beets, but was less effective with potatoes. This result is considered due to the shorter period of growth of the potato and its lower nitrogen requirements, and also to the cultural conditions of the crop, which favor the accumulation of available nitrogen in the soil during the vegetative period to a greater extent than is the case with beets and cereals.

A number of plats received no nitrogen, and although the experiments have been in progress for several years the yields have not diminished, and the same quantities of nitrogen have been taken up by the plants during the different years. Beets, potatoes, and wheat have given comparatively high yields, while barley after the beets, which draw heavily upon soil fertility, gave the lowest yield.

For the Lauchstädt soil the following quantities of nitrogen per hectare are recommended: For sugar beets (1) 60 to 75 kg. in two applications, either both in the form of nitrate of soda or the first one as ammoniacal superphosphate, and if barnyard manure was applied the year before the application should be a little less; (2) 40,000 kg. of barnyard manure and 200 kg. of nitrate of soda, or preferably 30,000 kg. of barnyard manure and from 200 to 300 kg. of nitrate of soda; (3) green manuring and from 200 to 300 kg. of nitrate of soda. For potatoes (1) 45 kg. in the form of nitrate of soda and ammoniacal superphosphate; (2) 30,000 kg. of barnyard manure and, if the same is of poor quality, from 100 to 200 kg. of nitrate of soda in addition. For winter wheat (1) 20 kg. of ammoniacal nitrogen given in the fall; (2) the second spring after applying barnyard manure, a top-dressing of 100 to 150 kg. of nitrate of soda, and the third spring a top-dressing of 200 kg. of nitrate of soda.

For barley, the first year following a heavy application of manure no nitrogen should be given; the second year 20 kg., and the third year from 20 to 30 kg. of ammoniacal nitrogen should be applied. For oats, the second year after manuring 30 kg., and the third year 45 kg., partly in the form of ammoniacal nitrogen. A top-dressing of sulphate of ammonia, especially on highly calcareous soils, was not found beneficial, and the results indicated that, in order to prevent the loss of nitrogen through the volatilization of ammonia, this substance should be mixed with ammoniacal superphosphate and worked into the soil immediately upon application.

Phosphoric acid increased the yields but little and proved unprofitable when used with barnyard manure. Heavy applications on plats receiving no barnyard manure were also unprofitable, and it is concluded that, for beets and potatoes grown without barnyard manure, from 50 to 60 kg., and for cereals, under the same conditions, from 40 to 50 kg. of phosphoric acid per hectare is sufficient for the particular soil.

Potash was effective wherever the crops were grown without the use of barnyard manure. Annual applications, however, are not recommended on account of the injurious effect upon the mechanical condition of the soil which is likely to result. Of the different crops the potato showed the greatest potash requirements. The following quantities of potash per hectare are recommended: Potatoes, 300 kg. of 40 per cent potash salt; beets, 300 kg. of 40 per cent potash salt, or from 800 to 1,000 kg. of kainit; cereals, from 400 to 500 kg. of kainit. The potash in sugar-house refuse was much less effective than that in 40 per cent potash salt.

The roots of fodder beets removed the greatest quantity of potash from the soil as compared with potatoes and sugar beets, the potatoes removing much more than the beets. The leaves of the sugar beets contained more potash than the leaves of the other root crops. On soil receiving only commercial fertilizers with no potash, sugar beets removed 225 kg. of potash per hectare, and potatoes only 44 kg. This result shows that the sugar beet is better adapted than the potato to the use of the potash in the soil, and it also explains why the potato has

such a high potash fertilizer requirement. The largest quantities of sodium were taken up by the fodder beets, the contents of the roots being especially high. The roots of sugar beets contained but little sodium, practically the entire quantity taken up by the plant being found in the leaves. The potatoes contained a very small quantity of this element, whether the soil was fertilized with barnyard manure, potash salts, or with nitrate of soda. Chlorin was most extensively used by the fodder beets, and also in comparatively large quantities by the potatoes. The roots of the sugar beets were very low in chlorin, nearly all of it taken up being found in the leaves. The fodder beets responded most readily to the use of crude potash salts, which contain a large quantity of sodium.

The square-head varieties of wheat gave the highest yields wherever they survived the winter. In general, these varieties are not very resistant to the cold season, and improvement by breeding to overcome this defect is recommended. The following varieties of cereals gave good results: *Winter rye*—Petkus and Heine Zeeländer. *Winter barley*—Bestehorn Giant and Groningen. *Summer barley*—Svalöf Chevalier, Heine Chevalier, Hanna, and Goldthorpe. *Oats*—Strube, Ligowo, Leutewitzer Yellow, and Beseler No. III. *Potatoes*—Cimbal Primel, Cimbal Yellow-Fleshed Table potato, Ella, Cimbal Early Prolific, Rosalind, and Up-to-Date.

The total dry matter produced per hectare in the roots of fodder and sugar beets was about the same, but when taking the leaves into consideration the larger quantity was produced by the sugar beets. Fodder beets planted 9x14$\frac{1}{2}$ in. produced more dry matter than those planted 12x18 in.

Field experiments in Staffordshire and Shropshire and at the Harper-Adams Agricultural College, Newport Salop (*Joint Rpt. 1903, pp. 25*).—At the college the results of manuring meadow land in 1903 showed that a complete dressing of commercial fertilizers gave the best results, although incomplete applications also increased the crop. Potash fertilizers did not cause a marked increase in yield of the herbage, but they materially improved its quality. The largest net profits, amounting to £1 17s. 2d. per acre, was obtained from an application of 1.7 cwt. of nitrate of soda, 2$\frac{1}{2}$ cwt. of superphosphate, and $\frac{1}{2}$ cwt. of sulphate of potash.

A test was made of 12 varieties of oats, including the white, yellow, and black types. New Abundance, a white oat, is considered the best variety, its yield in both grain and straw being very good. Heine German Prolific gave the largest yield, but its grain was not equal to that of New Abundance in quality. Among the black oats Excelsior gave promising results, but its straw was very stiff and coarse.

Fourteen varieties of mangels, including the Yellow Globe, Golden Globe, Golden Tankard, and Sugar Mangel types were grown for comparison. Carter Windsor, a Yellow Globe variety, led with a yield of 44 tons 4 cwt. per acre. The average yields for the Yellow Globe, Golden Globe, Golden Tankard, and Sugar Mangel varieties were 39.5, 28.75, 28.5, and 27.5 tons per acre, respectively. Each type produced 3.5 tons of dry matter per acre, with the exception of the Golden Globe varieties, which produced only 3 tons.

In a fertilizer experiment the largest increase in the yield of mangels, 10 tons 17 cwt., was obtained from an application consisting of 15 tons of barnyard manure, 3$\frac{1}{2}$ cwt. of dissolved bone, 1 cwt. each of sulphate of ammonia and nitrate of soda, and 4 cwt. of salt per acre. The addition of 4 cwt. of salt proved beneficial. Potash was not very effective. Fifteen tons of barnyard manure per acre seemed an average dressing for this crop. Home-mixing of the fertilizers was found profitable.

Among different fungicides, Bordeaux mixture proved to be the most effective in the prevention of finger-and-toe disease in swedes and turnips. Lime did not seem very effective.

In fertilizer experiments with swedes in Shropshire barnyard manure gave an increase over commercial fertilizers, and the need of this crop for phosphates was clearly shown. In this test also, home-mixing of the commercial fertilizers proved profitable as compared with the purchase of ready-mixed fertilizers.

In Staffordshire the results of experiments on manuring meadows show that a complete commercial fertilizer was most effective, being followed by barnyard manure at the rate of 12 tons per acre annually. The use of lime was not profitable. Barnyard manure gave a large increase in yield in every case, while nitrate of soda, basic slag, and kainit, applied singly, were not always effective.

In a variety test with potatoes, Scottish Triumph and Up-to-Date gave the best yields. Up-to-Date, however, is regarded as a variety showing signs of deterioration. Fertilizer experiments with potatoes indicated that an application of 20 tons of barnyard manure per acre is not so beneficial as an application of 10 tons with a complete mixture of commercial fertilizers. In experiments with mangels a large increase of crop was obtained by the substitution of 4 cwt. of kainit for the same quantity of salt, and it was also shown that a medium quantity of barnyard manure given with a complete commercial fertilizer is most profitable.

Field experiments [in Ireland], 1903 (*Jour. Dept. Agr. and Tech. Instr. Ireland, 4 (1904), No. 3, pp. 469–510*).—As in the 2 previous years, Archer Chevalier barley again produced larger yields than either Goldthorpe or Standwell. In quality it was inferior to the other varieties and the percentage of small grains was also higher. It was found that Archer Chevalier did not ripen as well under unfavorable weather conditions as the other varieties, but the loss of heads at ripening was considerably less. Archer Chevalier needs a dry soil, while Goldthorpe and Standwell do best on rich and stiff soils. The results of cooperative fertilizer experiments with barley vary considerably, and it is recommended that farmers consider principally the results obtained on their own lands. Commercial fertilizers proved profitable on soils in low condition, but on lands in good condition they did not give profitable results.

In a second variety test with barley on a smaller scale than the first, Archer Chevalier has in the 2 previous years produced a larger average yield than either Garton Brewers Favorite, Garton Invincible, Hallett, Pedigree, or Scotch Chevalier. The Garton varieties were low in yield, but in quality they were superior to the Chevalier varieties, and also seemed to mature better in unfavorable ripening weather. The results of the fertilizer tests show that 1 cwt. of sulphate of ammonia alone per acre retarded maturity, but when given with 3 cwt. of superphosphate the application produced a profitable average increase. The use of 3 cwt. of kainit per acre was not satisfactory, but where the kainit was applied with superphosphate only the quality of the grain was improved to such an extent that, although the yield was not the best, the profit was the largest.

The results of cooperative fertilizer experiments on meadows for the season, as well as those for the 2 previous years, indicate that in the different soils under test 1 cwt. of nitrate of soda, 2 cwt. of superphosphate, and 2 cwt. of kainit per acre can be profitably applied.

The report of the fertilizer experiments with potatoes shows that 20 tons of barnyard manure per acre apparently increased the yield by 5 tons and 1 cwt., and an application of 15 tons by 4 tons and 8 cwt. in one instance, and by 4 tons and 5 cwt. in another. Commercial fertilizers applied in addition to the lighter dressing of barnyard manure gave in all cases a larger yield than the heavier dressing of manure alone and also proved more profitable. Of the varieties of potatoes grown by all the experimenters Up-to-Date and Beauty of Bute produced the best crops.

Mangels were given 15 tons of barnyard manure per acre as a general application for a series of plats, and in some instances commercial fertilizers were added. The use of the manure alone gave a good profit and the addition of a complete mixture of commercial fertilizers increased the net profit by 37s. 6d. The substitution of 4 cwt. of salt for 2 cwt. of kainit in the application proved beneficial.

Experiments conducted with oats have shown that kainit applied alone is not satisfactory. The use of superphosphate and sulphate of ammonia each alone resulted in much smaller profits than the use of the 3 substances in combination. In a com-

parative variety test, Goldfinder, Canadian Banner, and Waverley led in productiveness with a yield of 22 cwt. and 2 quarters per acre each. These same varieties ranked first the year before.

In experiments with turnips a complete fertilizer gave better results than an incomplete application. In a second experiment 10 tons of barnyard manure and 4 cwt. of superphosphate per acre gave a slightly better yield than 20 tons of barnyard manure alone. The yields of varieties of swedes and of yellow turnips are given in a table.

Reports of Danish state plant experiment stations, 1903, F. HANSEN, K. HANSEN, N. P. NIELSEN, A. J. HANSEN, and L. HELWEG (*Tidsskr. Landbr. Planteavl, 11 (1904), pp. 303–323*).—An account of crop conditions at these stations during the season of 1903, with brief statements of the main results of plant culture experiments conducted during the year.—F. W. WOLL.

On the growing periods of crops in northern Norway, L. P. NILSSEN (*Tidsskr. Norske Landbr., 11 (1904), No. 6, pp. 235–272*).—Statistics and other evidence concerning crop production in northern and southern Norway were collected to test the hypothesis of Schübeler that, on account of the long summer days in northern latitudes, plants require a shorter growing period in these regions than they do farther south. Data regarding the time of sowing and harvesting of barley, oats, rye, peas, potatoes, and turnips; the time of first growth, blossoming, and cutting of meadow and timothy grass; blossoming and ripening of wild berries, and the fall of leaves are presented.

It is shown that the shortest growing periods are found in the inland counties, and that in general the time required to produce grass ready for cutting, or to ripen grain or potatoes, increases with the latitude until Finmarken is reached, where the requisite weather conditions for grain growing are not found. The average growing periods of various crops for a number of years in different sections of Norway, going from the south northward, are shown in the following table:

Average growing periods of crops in Norway.

Section of country.	Six-rowed barley.	Oats.	Spring rye.	Peas.	Potatoes.	Meadows, turning green to cutting.	Timothy, blossoming to seed formation.
	Days.	*Days.*	*Days.*	*Days.*	*Days.*	*Days.*	*Days.*
First	86.8	109.3	118.5	120.0	132.7	52	33.5
Second	92.9	112.3	114.4	116.7	130.1	56	40.2
Third	96.3	117.3	117.6	....	132.3	66	38.2
Fourth	100.9	127.3	115.5	132.5	133.8	65	40.0
Fifth	106.3	116.2	146.0	124.6	129.2	58	47.7
Sixth	103.7	120.3	....	....	104.8	69	61.0

The first section of the country includes the counties of Smaalenene, Jarlsberg, and Laurvig; the second, Akershus, Hedemarken, Kristian, Buskerud, and Bratsberg; the third, Nedenäs, Lister, and Mandal; the fourth, Stavanger, North and South Bergenhus, and Romsdal; the fifth, North and South Drontheim, and the sixth, Nordland, Tromsö, and Finmarken.

In view of these results the hypothesis of Schübeler is considered applicable only in those northern localities which have specially favorable soil and weather conditions. The causes operating against a short growing period in the north are prevailing cloudy weather during May and June, and low air and soil temperatures during the summer months. These disadvantages, as a rule, more than outweigh the influence of the prolonged sunlight of the summer days, and tend to reduce the luxuriance of the vegetation and to shorten the growing period of plants.—F. W. WOLL.

Hawkesbury Agricultural College and Experimental Farm, G. L. SUTTON (*Agr. Gaz. New South Wales, 15 (1904), No. 3, pp. 283–290*).—Varieties of wheat from

France, South Australia, South Africa, and Western Australia were grown to determine their rust-resistance rather than their productiveness, and the results are arranged in tabular form in the order representing their resistance to the disease. The variety Nutcut, the seed of which was obtained from Wagga, heads the list and is reported as being a fine wheat for hay and grain.

Notes are also given on the culture at the farm of alfalfa, cowpeas, swedes, rape, maize, and sorghum.

On the uncertainty of the hay crop at the agricultural college of Norway, G. HOLTSMARK (*Norsk Landmandsblad, 23 (1904), No. 27, pp. 319–321*).—Observations on the variations in the yields of hay during the 25 years 1878–1902 show that the average yield of hay on first year's meadow during this period has been 417 kg. per dekare, 487 kg. on second year's, and 424 kg. on third year's meadow. By applying the theory of probabilities, the probable variations from the average yields were found to be 121 kg., or 29 per cent, on first year's meadow; on second year's, 111 kg. (22.8 per cent), and on third year's, 102 kg. (24 per cent). Another method of computation gave a probable variation of 92 kg., or 20.5 per cent of an average yield.—F. W. WOLL.

Plan of culture trials at Danish plant experiment stations, 1904–5 (*Tidsskr. Landbr. Planteavl, 11 (1904), pp. 199–275*).—A detailed statement of the various experiments in progress or planned for the year 1904–5, at the Danish plant experiment stations at Lyngby, Tystofte, Abed, Askov, and Vester Hassing, as well as of cooperative experiments with root crops at various farms conducted under the direction of these stations.—F. W. WOLL.

Yields obtained on light sandy soil without the use of barnyard manure (*Deut. Landw. Presse, 31 (1904), No. 54, p. 483*).—The yields of potatoes and winter rye for 10 years are recorded. The rotation consisted of yellow lupines for green manuring grown without a nurse crop and with the use of commercial fertilizers, potatoes without commercial fertilizers but receiving the benefit of the green manure, and winter rye with applications of commercial fertilizers. The plats were 1 morgen in size and received for lupines annually 600 lbs. of kainit. For the first crop of lupines each plat received 300 lbs. of Thomas slag, and 150, 200, and 150 lbs. for the second, third, and fourth crops, respectively. The potato plats received 100 lbs. of Thomas slag and 250 lbs. of kainit each year. Half of the experimental field received 1,100 lbs. and 1,250 lbs. of marl per morgen in 1895 and 1899, respectively.

The rye produced an average yield of 11.25 cwt. of grain and about 26 cwt. of straw per morgen. The use of marl increased the yield of rye by 61 lbs. per morgen, and the yield of potatoes by 13.5 cwt., and also seemed to have reduced the scab in the potato crop. The average yield of potatoes for the 10 years was 84.9 cwt. per morgen.

Staple crops, E. B. FERRIS (*Mississippi Sta. Bul. 83, pp. 16–34*).—The experiments here described are similar to those previously reported (E. S. R., 15, p. 142). Fertilizer experiments conducted with corn, cotton, sweet potatoes, and Spanish peanuts, showed that phosphatic and nitrogenous fertilizers increase the yields of these crops on the station soil. Phosphoric acid was more effective than any other element. The use per acre of from 125 to 200 lbs. of a mixture consisting of 750 lbs. of cotton-seed meal and 1,250 lbs. of acid phosphate is recommended for corn and cotton.

In the different variety tests the following were the most productive sorts: *Corn*—White Majestic and Major Berry; *cotton*—Duncan Mammoth Big Boll Prolific and Shine Extra Early Prolific; *cowpeas*—Unknown, Whip-poor-will, Southdown, and New Era. Among different forage crops teosinte ranked first in yield. Cowpeas planted at the rate of 60 lbs. of seed per acre yielded 2,520 lbs. of hay per acre, while half that quantity of seed gave 2,440 lbs.

Study of the variation in mineral matter during the ripening of seeds (*Compt. Rend. Acad. Sci. Paris, 138 (1904), No. 26, pp. 1712–1714*).—The results are

reported of determinations of the mineral matter in white lupines on July 4, 11, 17, 27, 30, and August 10, 22; and of Spanish beans August 19, 27, September 4, 11, 21, and October 2, 16.

There was an increase in the total ash in both hulls and seeds of lupines up to August 10. In the beans there was an increase in the case of the hulls up to September 21; in case of seeds until October 16. The lime and magnesia increased steadily during the earlier stages of growth, but declined toward the end of maturity in case of the hulls of both lupines and beans. In case of the seeds, however, there was a continuous increase up to the end of ripening. Potash increased throughout in total amount, but the percentage remained constant in the hulls and declined in the seeds. Phosphoric acid increased up to a certain point and then decreased in the hulls, although it did not appear to migrate to the seed to any considerable extent.

Composition of tubers of different varieties of Jerusalem artichoke harvested in spring and fall, P. BEHREND (*Jour. Landw., 52 (1904), No. 1–2, pp. 127–143*).—Historical notes on the study of the chemical composition of Jerusalem artichoke tubers are given and the author's work is described. Analyses of 7 samples each of fall harvested and spring harvested tubers are reported. In each case the composition of the fresh sample and of the dry matter is given.

Analyses of 3 samples, made from 3 to 4 months after storing, are also reported. A summary of the analyses is given in the following table:

Composition of Jerusalem artichoke tubers of spring and fall harvesting.

	Water.	Dry matter.	In dry matter. Water soluble matter.	Crude protein.	Crude fat.	Nitrogen-free extract.	Crude fiber.	Ash.	Pentosans.	Total carbohydrates.	Total nitrogen.

Variety tests with barley, W. EDLER (*Fühling's Landw. Ztg., 53 (1904), Nos. 9, pp. 328–331; 10, pp. 372–376; abs. in Deut. Landw. Presse, 31 (1904), No. 22, pp. 254, 255*).—Twelve cooperative tests were made with Goldthorpe, Chevalier, and Hanna barley. The average yields of grain per hectare were 3,316 kg., 3,252 kg., and 2,843 kg., and the average yields of straw, 4,111 kg., 4,090 kg., and 3,862 kg., respectively. The average weight per liter was 692 gm., 688 gm., and 685 gm. for Chevalier, Hanna, and Goldthorpe, respectively. Goldthorpe stood first in the weight per thousand grains, and was followed by Chevalier and Hanna in the order given. The weight per thousand grains in the series of tests varied from 43.26 gm. to 50.48 gm. In mealiness Goldthorpe ranked first and Hanna last.

The results also show that the locality had a marked influence on the mealiness of the grain. Goldthorpe contained 10.10 per cent of protein in the dry matter, Chevalier 10.62 per cent, and Hanna 10.73 per cent. Attention is called to the following classification of brewing barley as based on the protein content: Under 9 per cent of protein in the dry matter first grade, 9 to 10.5 per cent second grade, 10.5 to 11.5 per cent good, and over 11.5 per cent medium and poor.

Final report of experiments with malting barley and wheat, 1893-1902, C. SONNE (*Tidsskr. Landbr. Planteavl, 11 (1904), pp. 56–134*).—This report finishes the extensive work done by a committee of the Royal Agricultural Society of Denmark, under the direction of the author, in determining the most desirable varieties

of wheat and malting barley for Danish farmers. The trials of the committee cover a period of 20 years, and a report for the first 10 years has been previously published (E. S. R., 5, p. 716; 9, p. 941).—F. W. WOLL.

Roo crops adapted to culture on moor soils, H. VON FEILITZEN (*Svenska Mosskulturför. Tidskr., 18 (1904), No. 4, pp. 294–302*).—Experiments made at Flahult Experiment Station during 1897–1902 show that turnips gave the most certain and the largest crops, while carrots, Swedish turnips, and especially fodder beets produced very small yields. Bortfelder and Early Improved turnips, and Champion, White Belgian, Giant, Orange Yellow, and James carrots were the most valuable varieties grown.—F. W. WOLL.

Experiments with buckwheat, S. TRETYAKOV (*Zhur. Opuitn. Agron. [Jour. Expt. Landw.], 5 (1904), No. 1, pp. 1–17*).—Since 1895 Common Siberian and Silver Hull buckwheat have been grown in comparison on the Poltava Experiment Field. In 1901 and 1903 the common buckwheat was grown on tilled and fallowed forest land of a clay soil, and also on cultivated and fallowed chernozem. In 1902 seeds of different weight of this same variety were tested. The seeds weighed 1.362, 1.998, and 2.198 gm. per 100, corresponding to a mesh of 1, 2, and 4 mm., respectively.

The average results for the years 1895 to 1902, inclusive, show that Siberian buckwheat yielded 870.6 lbs. of grain and 2,079.6 lbs. of straw, and Silver Hull buckwheat 735.5 lbs. of grain and 2,510 lbs. of straw per acre, the ratio of straw to grain being 2.7 and 4.1, respectively. The author concludes that buckwheat comes up quicker on chernozem soil, but that the period of growth is longer than on forest clay. Owing to the higher moisture content and the greater fertility of chernozem as compared with the other soil, the yields of grain and straw are heavier. On the fallow of both soils the development of the crop was weaker and the yield was slightly less than on the soil continuously under cultivation. Small and light but plump kernels of buckwheat are richer in nitrogen and ash than plump, heavy, large kernels. The results of a 1-year's test indicated that the largest yields are obtained from plump small seed and the lowest from seed of medium size and weight. Siberian buckwheat succeeds better at Poltava on account of its shorter growing period.—P. FIREMAN.

A study of correlative characters in Székler maize, C. FRUWIRTH (*Fühling's Landw. Ztg., 53 (1904), Nos. 6, pp. 200–208; 7, pp. 255–258*).—The weight of the whole plant, ear, stalk and leaves, husks and cob, and the percentage of grain and stalk based on the total weight of the plant, and of husks and cob based on the weight of the ear, were determined and are recorded in tables.

The single-eared plants produced from seed of 6 selected stalks were grouped according to their maturity. Late ripening appeared correlative with a high weight of the entire plant as well as with a high weight of grain, husks, cob, and ear. The percentage of the cob to the ear by weight was in all cases greater in the late maturing plants than in the early ones, but the percentage of grain was lower. A high total weight of the plant is not regarded as a very definite factor in grain production.

In selecting for improvement a high yield, coupled with a high per cent of grain, is considered of first importance. A long ear usually indicated a high weight and high percentage of grain and a high weight of kernel, but the percentage of cob and husks was also high, and these qualities are regarded as unfavorable. A heavy development of the husks retards ripening in the regions where the variety is grown. A large number of internodes was apparently connected with a high weight of grain per plant, a low weight of kernel, a low percentage of grain, and a high percentage of cob, and was indicative of a high production of stover. A thick stalk, being associated with a low percentage of grain and a high percentage of cob, did not seem to be a favorable factor.

Manuring of cotton, G. P. FOADEN (*Jour. Khediv. Agr. Soc. and School Agr., 6 (1904), No. 1, pp. 1–6*).—This article discusses the manuring of cotton, and incident-

ally embodies the results of some experiments along that line. For general purposes an application of 60 kilos of nitrate of soda, 40 kilos of sulphate of ammonia, and 400 rottolis of superphosphate per feddan are recommended. This application gave profitable results in the several experiments reported. The application was also found profitable when applied together with 10 cubic meters of barnyard manure. The results further showed that the bulk of the nitrogen applied should be in the form of nitrate of soda. Practically no increase was obtained by the use of potash manures.

Flax and linseed industry, J. KNIGHT (*Guides to Growers [Dept. Agr., Victoria], No. 50, pp. 16, figs. 9*).—This is a popular bulletin on the culture of flax, with special reference to conditions obtaining in Victoria.

Gram (*Bul. Dept. Agr. Jamaica, 2 (1904), No. 9, pp. 202, 203*).—Data regarding the composition of gram or chick-pea are quoted.

Job's tears seeds, H. H. COUSINS (*Bul. Dept. Agr. Jamaica, 2 (1904), No. 9, p. 202*).—Analyses by H. S. Hammond are reported.

Jute culture, L. HAUTEFEUILLE (*Agr. Prat. Pays Chauds, 3 (1904), No. 18, pp. 647–657, figs. 2*).—Culture and fertilizer experiments are reported from Bat-Bat, Indo-China. Jute was grown on soil worked 25, 40, and 60 cm. deep, but the depth of cultivation had no effect upon the development of the plants.

Mineral superphosphates, applied at the rate of 1,600 kg. per hectare, remained without effect because the phosphoric acid did not become available in time for the crop. Ashes had a marked influence, especially on the early growth of the plants, and are believed to have acted not only as a source of plant food, but also in the line of improving the soil. Other results obtained indicated that jute can profitably be cultivated by the native system, in which night soil is used as a fertilizer.

Variation in oat hybrids, J. H. WILSON (*Nature, 69 (1904), No. 1792, p. 413*).—The results of crossing white varieties of oats, and also black varieties with white ones, are reported. The author concludes from the study of available samples that the form of the ear will no doubt be found to be a constant Mendelian character. The material examined further showed the dissociation of the color of the grain. A summary of the results is shown in the following table:

Results with different oat hybrids.

Hybrids.	Number of grains sown.	Number of plants harvested.	Number with black grains.	Number with white grains.	Ratio of black to white grains.
Goldfinder × Black Tartarian	1,000	567	433	134	3.23:1
Goldfinder × Black Tartarian	900	566	415	151	2.75:1
Black Tartarian × White Canadian	800	532	379	153	2.48:1
Black Tartarian × Abundance	600	274	209	65	3.21:1

The Black Tartarian oat with reference to color of the grain was dominant, whether serving as pollen or seed parent. The proportion of black to white forms in the second generation closely approximated 3:1.

Drying tobacco leaves either primed or on the stalk, E. C. J. MOHR (*Landw. Vers. Stat., 59 (1903), No. 3–4, pp. 252–292; abs. in Centbl. Agr. Chem., 33 (1904), No. 7, pp. 459–461*).—Experiments are reported from which the conclusion is reached that, contrary to opinions held by earlier investigators, if tobacco leaves are allowed to dry on the stalk many substances of the greatest importance to the production of the seed and the development of the buds and shoots are transported in considerable quantities from the leaves to the stem.

Of the ash constituents, lime and magnesia are largely stationary. Sulphuric acid moves in greater quantities and is exceeded in translocation by chlorin and potash, while phosphoric acid is the most readily transported substance. Attention is called

to the movements and changes of the carbohydrates and the absence of these substances in properly dried leaves. With reference to the nitrogen compounds, the author states that the albuminoids and nicotin have a low movability, while ammonia and nitric acid, and especially the amids and amins, show a high power of translocation. The greater portion of the substances translocated within the plant were alkaline. The effect of the removal of the leaves on the production of seed is discussed.

Vetch sown with oats on fallow, F. GUBINE (*Zeml. Ghaz., 1903, No. 30, pp. 123, 124; abs. in Zhur. Opuitn. Agron. [Jour. Expt. Landw.], 5 (1904), No. 1, pp. 115, 116*).—The results of growing vetch with oats for a series of years at the Moscow Agricultural Institute show that this crop draws heavily upon the soil moisture, and that it is detrimental to an immediately following crop of winter rye. The yield of winter rye under these conditions is reduced from 30 to 35 per cent as compared with the yield on black fallow.—P. FIREMAN.

Observations on winter wheat in the Kherson Government, P. N. KOZLOVSKI (*Vyestnik Selsk. Khoz., 1903, Nos. 14, 15, 18, 23, 26; abs. in Zhur. Opuitn. Agron. [Jour. Expt. Landw.], 5 (1904), No. 1, p. 114*).—The development of winter wheat on different kinds of fallow is described in detail. At the time of sowing black fallow contained 18.4 per cent of soil moisture at a depth of 10 cm., while American corn fallow contained only 9.21 per cent. The crop on black fallow came up 26 days earlier and was much better developed at the beginning of winter than the crop on corn fallow. Although rains were plentiful the following spring the wheat on the black fallow retained this decided advantage.—P. FIREMAN.

Macaroni wheat in foreign markets (*U. S. Dept. Com. and Labor, Spec. Consular Rpts., 29 (1904), pp. 76*).—A series of reports by the consular officers of the United States in Europe, Northern Africa, and Argentina on the production and consumption of macaroni wheat in their districts.

HORTICULTURE.

Report of the horticulturist, A. T. JORDAN (*New Jersey Stas. Rpt. 1903, pp. 289–345*).—The records of another year showing the yields with asparagus and a number of small and orchard fruits, when differently fertilized and cultivated, are reported. This work has been under way for a number of years (E. S. R., 15, p. 149), and summaries are given of the results thus far obtained with asparagus and raspberries for the whole period. These summaries have been published in bulletin form and noted previously (E. S. R., 16, p. 262). The usual meteorological data are incorporated in the report.

In the fertilizer work with asparagus and small fruits a comparison is being made of the relative value of barnyard manure, a complete commercial fertilizer, the same fertilizer plus bone and potash, and the same fertilizer plus bone, potash, and nitrate of soda. Duplicate plats in each case are irrigated.

Irrigation has increased the total yield of raspberries on the average about 2 per cent. With blackberries irrigation has increased the average yield 4½ per cent. Early Harvest, Eldorado, and Erie have given the largest yields in the order named. With irrigation the heaviest yield has been obtained on the manured plat. Without irrigation the heaviest yield was obtained on the plat receiving complete fertilizer plus bone and potash. With currants the average yield from the irrigated plats exceeds that from the unirrigated by 9½ per cent. The largest yields both with and without irrigation have been obtained on the manured plats.

A record is given of the yields of a number of individual currant bushes, which shows the production of individual bushes of the same variety to vary between 1,405.2 to 6,149.4 qts. per acre. With gooseberries the average yields for 6 years are slightly in favor of irrigation. Similarly manured plats have averaged larger in yield than the plats fertilized with complete commercial fertilizer.

The records of yields are given for a number of varieties of strawberries and for a number of orchard fruits set in permanent plats. No striking results have been brought out in these trials as yet.

Experiments in crossing plants, B. D. HALSTED and J. A. KELSEY (*New Jersey Stas. Rpt. 1903, pp. 463–490, pls. 6, dgm. 1*).—Data in continuation of that previously noted (E. S. R., 15, p. 152) are given showing the results obtained in growing the progeny of crosses of different varieties of sweet corn, salsify, eggplants, cucumbers, squashes, tomatoes, Wax beans, and Lima beans. The account of the development of the Voorhees Red variety of sweet corn, which the authors originated by crossing Black Mexican with Egyptian, has been noted from another source (E. S. R., 15, p. 1075). A plate is given showing the character of the cross obtained between Black Mexican and Country Gentleman varieties of sweet corn. Country Gentleman appears to be easily fertilized by the Black Mexican, while Black Mexican is only rarely crossed with Country Gentleman.

Seed of the third-generation stock of eggplant began fruiting as early as plants of the parent types—New York Improved and Early Long Purple; and, while some of the fruits resembled those of the parents, the majority were more or less bell-shaped. Illustrations are given of some Japanese eggplants. Crosses of New York Improved eggplants upon Black Snake gave fruits 10 to 12 in. long and 3 to 4 in. in diameter. The quality is noted as excellent, and the shape desirable from a culinary standpoint. Other eggplant crosses were made as follows: Long White upon New York Improved, Round White upon Black Pekin, Fordhook Improved upon Mammoth Pearl. Special attention is called to the remarkable vigor of crosses of Long Purple and New York Improved.

Illustrations are given of variations in cucumbers obtained by crossing White Spine and White Pearl, and also Telegraph upon Znaim.

A number of varieties of tomatoes were tested, the heaviest yielding of which was Magus. Of 3 varieties of dwarf Lima beans tested Burpee gave more than double the yield of either of the other two. Henderson was the earliest maturing of the 3 varieties and had a longer fruiting period. In another test Henderson and Willow Leaf proved more productive than Burpee, Thorburn, or Dreer.

Proceedings International Conference on Plant Breeding and Hybridization (*Hort. Soc. New York Mem., 1 (1902), pp. 271, figs. 15*).—This is a report of the papers and discussions before the International Conference on Plant Breeding and Hybridization, held under the auspices of the Horticultural Society of New York, September 30 and November 1–2, 1902. An account of this conference has already been presented (E. S. R., 14, p. 208).

Proceedings of the fruit culture conference held in connection with the Irish-grown fruit show at the Cork International Exhibition (*Dept. Agr. and Tech. Instr. Ireland, 1902, pp. 23*).—The proceedings are made up of a number of papers, by as many different authors, on various phases of fruit culture in Ireland, the trend of the papers being the encouragement of the development of fruit growing in Ireland.

Fruits and vegetables, E. B. FERRIS (*Mississippi Sta. Bul. 83, pp. 7–15*).—Brief notes, with tabular data in some instances, are given on results of variety tests with a number of garden beans, tomatoes, watermelons, strawberries, and miscellaneous fruits and vegetables.

Cantaloupe culture, W. F. ALLEN (*Rpt. Maryland State Hort. Soc., 5 (1902), pp. 82–86*).—The author grows cantaloupes on an extensive commercial scale in Maryland. After the land has been thoroughly prepared, he plows out furrows about 8 in. deep and $4\frac{1}{2}$ to 5 ft. apart, going twice in the same row in order to broaden out the trench. The trench is then about half filled with compost or stable manure, and thoroughly mixed with the soil by cultivating up and down the row 4 times or more. In order to prevent loss from frost or insects and to insure a stand, at least 3 sepa-

rate plantings are made beside each other about a week apart. If the first planting is killed by frost, the second one may come up; whereas, if the second planting were delayed until after the frost appeared, there would be a loss in earliness of 10 days or more.

In harvesting the melons the first half of the season they are picked as soon as the stem can be forced with the thumb to part from the fruit without breaking off a piece of the melon with it. This condition should occur before the cantaloupe begins to turn yellow. A cantaloupe in this condition is considered just right to ship, but the day following would be quite yellow and unfit for transportation. "After the season is one-half or two-thirds gone and the weather is very hot, as is usually the case, I find it safe to cut them off with stems after they are full grown and have become densely netted." As no cantaloupes are picked on Sunday, many melons are overripe on Monday, and these are the ones that are saved for seed. It is important that the melons be stored in the refrigerator car as soon after picking as possible.

Blanching of wild chicory, V. ENFER (*Rev. Hort. [Paris], 76 (1904), No. 20, pp. 501–503*).—Blanched chicory is also known under the name of *Barbe de capucin*. Directions are given for harvesting the wild roots and preparing them for forcing for the production of blanched stems and leaves.

The chocho, A. F. T. SOMERVILLE (*Agr. Gaz. New South Wales, 15 (1904), No. 9, pp. 835, 836, fig. 1*).—The chocho appears to be another name for the chayote (*Sechium edule*). This vegetable appears to grow remarkably well in the colony, account being given of a 2-year-old vine which yielded 300 fruits. Two fruits are reported as sufficient for a meal for four persons. Directions are given for cooking this vegetable.

Concerning the chemistry of fruits, K. WINDISCH and K. BOEHM (*Ztschr. Untersuch. Nahr. u. Genussmtl., 8 (1904), No. 6, pp. 347–352*).—The authors studied the kind and amount of nitrogenous constituents and sugars in fruits, as well as the amount of pectin and tartaric acid. It was found that the proportion of coagulable albumin was very small. In many cases the amount was so small that filtered fruit juice when heated remained perfectly clear. The amount of true protein estimated by the Stutzer method was also in general very small.

As regards the ammonia and amid nitrogen, relatively large amounts of these constituents and of total nitrogen were found in all the varieties of grapes examined. Much smaller amounts were found in the cherries, plums, peaches, quinces, berries, and other fruits examined. The small amount of these constituents was especially noticeable in the case of blueberries and bilberries. The authors believe that the fermentation of must is in a large measure dependent upon the kind and amount of nitrogen present, and note that the nitrogen of ammonia and organic acid amids is most readily available for yeasts.

As regards the character of the sugars present in fruits, saccharose was found in every case in apples and pears. Apparently in the case of peaches saccharose was much more abundant than invert sugar. Saccharose was also noted in mulberries, cherries, plums, peaches, and black currants, fruits which are usually referred to as saccharose-free.

According to the authors' observations, the pectin content of a number of fruits examined in general diminished as the fruit ripened. The analyses reported showed that tartaric acid in general occurs, if at all, in very small amounts in most fruits and plays a valuable rôle only in the case of grapes.

Further notes on fruit growing in Tasmania, G. QUINN (*Jour. Agr. and Ind. South Australia, 8 (1904), No. 2, pp. 69–78, figs. 7*).—Special attention is called in this article to the desirability of pruning apple and pear trees to low forms with a very short trunk and with arms subdivided until from 8 to 15 leaders are secured. The leaders are not again bifurcated, but at each winter's pruning growth from one bud only is permitted to ascend in order to continue the extension and leading

direction of the branch. Some vigorous trees are summer pruned and the formation of fruit-bearing twigs thus encouraged. It is believed that trees thus pruned are much more capable of resisting sun scald, drought, and wind storms than where the branches are not shortened in and the tree allowed to develop into long branches which bend and break when heavily loaded with fruit.

Pruning, W. J. ALLEN (*Agr. Gaz. New South Wales, 15 (1904), No. 8, pp. 798–800, figs. 3*).—Illustrations are given of the difference in appearance and the more fruitfulness of apples and pears when well pruned than when allowed to grow naturally. On the unpruned trees the bulk of the fruit is borne far out on the ends of straggling branches which are thus bent to the ground. In order to prevent the trees from being broken it is necessary to remove a large quantity of the fruit or to prop up the limbs. On well-pruned trees the limbs are sturdy and upright and the fruit is borne close to the body of the tree and no props are needed.

The stub-root system of tree planting (*Amer. Agr., 74 (1904), No. 17, pp. 345, 346*).—The experience of a number of orchardists who have planted fruit trees according to the stub-root system of pruning are here recorded. J. S. Harris reports that the system is not suited to the climate and soil of Kent County, Md. G. G. Hitchings, who planted a block of 1,000 peach trees, every alternate row being pruned according to the stub-root system, reports that the first year trees pruned in the regular way started out better and kept ahead all the season. The second year, however, the stub-root pruned trees did as well as the others, and it was difficult to detect any difference in the appearance of the trees differently root pruned. Mr. Hitchings' orchard is located in Onondaga County, N. Y.

Experimental studies in arboriculture, L. DANIEL (*Jardin, 18 (1904), Nos. 421, pp. 268–270, figs. 4; 422, pp. 276–278, figs. 7*).—The results are given of experiments in pruning pear trees by a method which the author calls *à onglet complet*. This method of pruning differs from the ordinary method in that the branch or shoot, which would ordinarily be pruned off entirely, is left on the tree and all of the buds on the branch are removed, including the top bud.

As a result of this method of pruning all of the wounds on the branch heal over. The branch remains alive for one or more seasons and requires a certain amount of food for its nourishment. It acts, then, as a kind of parasite on the tree, reducing its vigor. By this method of pruning it is claimed that more fruit is obtained than by the ordinary method, the theory being that a reduction of vigor induces fruitfulness.

A number of other phenomena caused by pruning *à onglet complet*, such as fasciation, the conversion of leaf buds into flower buds, and the abnormal swelling of certain shoots, due to bud growth, which takes place underneath the bark without bursting through, and the appearance of a second and even third crop of flower buds in the same season, are noted. Several of these abnormalities are illustrated.

Thinning of orchard fruits, C. F. AUSTIN (*Rpt. Maryland State Hort. Soc., 5 (1902), pp. 110–116*).—A discussion of this subject, with a review of the results which have been secured at the experiment stations along this line with different fruits.

The apple industry in Tasmania, W. J. ALLEN (*Agr. Gaz. New South Wales, 15 (1904), No. 9, pp. 815–819, figs. 3*).—An account of apple production in Tasmania, with estimates as to the cost of preparing the land for orchards and the yield of fruit which may be obtained upon an acre. The cost of clearing the land and planting the trees is placed at about $400 per acre. When the orchard comes into bearing it is estimated that the average yield will be about 300 cases per acre, which, after paying for all expenses of picking, packing, and marketing, should net about $150.

The winterkilling of Baldwins, U. P. HEDRICK (*Nat. Nurseryman, 12 (1904), No. 11, p. 141*).—The author calls attention to the failure of Baldwin apples in Michigan. At the Agricultural College 3 plantings of Baldwins have been made, but there is not now a bearing tree on the place, all having succumbed to the cold. The past

winter has been especially severe on this variety. Practically all of the trees outside of the peach region have been injured or killed, and many trees have suffered in localities where peaches have grown. In the northern counties of the State it is reported that all Baldwins have been killed. It appears to the author that the Baldwin apple is not more hardy than the peach, and should not, therefore, be grown outside of peach regions. The author believes, however, that the Baldwin apple can well be dispensed with, since there are a number of other varieties which are much more satisfactory in Michigan as a dessert apple.

The orange in northern and central California, E. J. WICKSON (*San Francisco: California State Board of Trade [1904], pp. 11, pl. 1*).—Attention is called to the desirability of northern and central California as a locality for the growing of citrus fruits. The oranges of northern California ripen in advance of those of the southern part of the State, chiefly on account of the influences exerted by the presence of the Coast Range which serves as a wind-break. Some suggestions are given on locating citrus orchards in this region.

The story of the papaw, F. B. KILMER (*Bul. Dept. Agr. Jamaica, 1 (1903), No. 8, pp. 181–189; 2 (1904), Nos. 4, pp. 84–91; 5, pp. 113–119; 8, pp. 178–181; reprinted from Amer. Jour. Pharm., 73 (1901), pp. 272–285, 336–348, 383–395, figs. 14, map 1*).—An account of the botany, characteristics, and culture of the papaw (*Carica papaya*), with detailed results of the chemical study of the milk of the papaw, including analyses of papaw latex, papaw proteids, ferments, glucosids, and alkaloids. The analytical methods employed are noted. An account is also given of market preparations of the papaw, of experiments on the digestive action of the ferment of the papaw, and of the products of digestion by the papaw ferment.

Peach trees in winter, W. F. FLETCHER (*Country Gent., 69 (1904), No. 2693, pp. 818, 819*).—The author made an investigation of the injuries to peach trees caused by the severe weather during the winter of 1903–4. In overcoming the injurious effects of winter freezing the author found that moderate pruning, good culture, plenty of fertilizer, and a close watch on insect pests were the best tonics for a frozen tree. Trees at high elevations suffered less than those in low places. Trees having a general exposure were less affected than those in sunny, sheltered pockets. It was found that moisture in the bark of the trees during the first few warm days of early spring indicated life in the stem or roots.

Japanese persimmons, H. H. HUME and F. C. REIMER (*Florida Sta. Bul. 71, pp. 68–110, figs. 9*).—Notes are given on the history of the Japanese persimmon in the United States; the botany of the persimmon, with a classification and description of varieties, and cultural notes, including directions for propagating, fertilizing, cultivating, pruning, and marketing. Several insects which affect persimmons are described by H. A. Gossard and remedies suggested for their control. A bibliography of 46 papers on Japanese persimmons is appended.

The authors classify Japanese persimmons into light-fleshed varieties, dark-fleshed varieties, and mixed-fleshed varieties. They state that, as a rule, dark-fleshed varieties and seeds accompany each other in the case of Japanese persimmons, though Triumph is an exception to this rule. A certain correlation was found between the shape of the fruit and the shape of the seeds. An illustration is given showing the shape of the seeds of 16 varieties.

The ripening season of Japanese persimmons is such that the early varieties come into competition in the north with late peaches and grapes, and the late varieties with apples and early oranges. For home use the authors recommend varieties covering the whole season, as follows: Yemon, Tanenashi, Zengi, Costata, Triumph, and Tsuru. For commercial purposes the following varieties are recommended: Yemon, Tabers No. 129, Tanenashi, Hachiya, Hyakume, Costata, Triumph, and Tsuru.

The American persimmon (*Diospyros virginiana*) is considered the best stock for Japanese varieties, as it is larger and more vigorous than the Japanese stock. The

seed of American persimmons should be sown in seed beds and transplanted to the nursery after they have attained a height of 10 to 12 in. In the nursery it is recommended that they be set 6 in. apart in rows 2 ft. apart. Grafting rather than budding is considered advisable, and crown grafting is considered much superior to root grafting. Whip grafting is preferred to cleft grafting in Florida. The authors state that budding is not successful with the persimmon in Florida, and this method of propagation should not be employed. In the orchard Japanese persimmon trees should stand 15 to 20 ft. apart each way.

As a result of experimental work at the station it is recommended that fertilizers for the persimmon should contain 3 per cent nitrogen, 6 per cent phosphoric acid, and 10 per cent potash. They should be applied at the rate of about 5 lbs. per tree for trees 6 years old. Experiments to determine the relation of the amount of potash in the fertilizer and the dropping of the fruit of the persimmon have given only negative results. It has been noted that older trees do not drop their fruits to as great an extent as younger trees. Persimmons should be gathered when fully matured but still firm.

Shipments to a number of northern horticulturists were made of persimmons in boxes and baskets. Generally, the fruit arrived in good condition, which shows that with care there need be no difficulty in the shipment of this fruit to northern markets. Directions are contained in the bulletin for preserving persimmons.

Pineapple culture, II. Varieties, H. H. HUME and H. K. MILLER (*Florida Sta. Bul. 70, pp. 36-62, pls. 10, figs. 4*).—This bulletin classifies and describes the pineapples cultivated in this country, noting the botanical features. Pineapples are divided into 3 groups, namely, the Queen, Cayenne, and Spanish. The typical variety of the Queen group is the Golden pineapple. The fruit of this variety "is characterized by yellow flesh, pointed eyes sloping upward from the sides, deep yellow fruit, and sirupy juice; flavor rich and sweet. Plants usually not adapted to open field culture." The Smooth Cayenne is taken as the type of the Cayenne group. "The flesh is a light yellow, the eyes broad and flat, not elevated at the nipple. The leaves are smooth or serrated; the plants are strong, upright, vigorous growers." In the Spanish group the typical variety is Spanish. "The flesh is white, the eyes are flat but elevated at the corners of the bracts. The leaves are strong, stiff, and serrated."

It is stated that the varieties of pineapples cultivated in this country have been introduced from Brazil, the West Indies, India, or from the greenhouses of England. Of the varieties now grown in Florida fully 95 per cent are of the Spanish variety. At least 99 per cent of all the plantings in the State are Spanish, Cayenne, Abachi, Porto Rico, and Golden. This list contains practically all of the varieties grown for commercial purposes. "For extensive open-field culture the Spanish pineapple is the only variety which can be recommended." The other varieties mentioned may be grown in a small way in the open field, but plantations of the same are too short lived to compete with the Spanish variety. Under sheds the varieties Cayenne, Abachi, and Golden are given the preference; and of these Cayenne is considered the best. The edible portion of a number of varieties and the composition of the same varieties with reference to ash, nitrogen, sugar, juice, etc., were determined by the authors and are shown in the following table (p. 469).

Composition of pineapples.

Variety.	Average weight of fruit.	Edible portion.	Total solids.	Soluble solids.	Ash.	Nitrogen.	Available juice.	Juice.	
								Acids as sulphuric.	Total sugars.
	Ounces.	*P. ct.*	*P. ct.*	*P. ct.*	*P. ct.*	*P. ct.*	*P. ct.*	*P. ct.*	*P. ct.*
Abachi	40.0	65.3	11.98	11.40	0.41	0.056	80.7	1.05	10.55
Spanish	59.0	59.3	12.64	11.44	.46	.063	87.2	1.35	10.22
Cayenne	78.0	62.8	14.40	13.38	.42	.089	85.5	.60	13.37
Red Ceylon	58.0	57.0	10.61	8.64	.43	.076	80.0	1.03	7.73
Egyptian	29.0	50.0	16.00	14.01	.43	.052	74.6	.81	12.21
Golden	55.0	65.4	13.27	12.16	.42	.057	86.6	.62	11.98
Porto Rico	146.0	67.0	13.60	11.22	.47	.069	87.5	.76	11.61
Enville	66.0	57.5	12.45	11.16	.61	.074	79.4	.59	10.57
Prince Albert	44.0	61.3	13.66	12.25	.69	.061	84.3	1.19	11.35
Sugar Loaf	38.7	57.3	10.76	9.76	.48	.066	85.6	2.11	8.49
Rothchild	40.5	63.5	9.90	8.76	.57	.083	84.9	1.28	6.64
Wild	23.5	50.0	10.51	6.77	.75	.190	78.5	2.00	4.28

Another table is given which shows the composition with reference to sugars and acids of the various parts of the pineapple. From the figures given it is shown that the sugar decreases and the acid increases from the base to the crown of the fruit, and from the core to the circumference. The sweetest fruit, therefore, of the pineapple is at the base near the core.

Cacao manurial experiments at Grenada (*Agr. News [Barbados], 3 (1904), No. 66, p. 347*).—The amount of cacao obtained during each of the years 1900 to 1904 on plats fertilized with manure and with different quantities and combinations of commercial fertilizers are tabulated. No conclusions are drawn.

Facts as to date culture, A. V. STUBENRAUCH (*Pacific Fruit World, 18 (1904), No. 5, p. 7*).—This article was written for the purpose of cautioning intending date planters not to be too hasty in setting out large orchards in the vicinity of the Salton basin until further experimental work shall determine just what varieties will best succeed and just what difficulties may be encountered in the work.

While theoretical considerations as to summer climate may show the Salton basin to be especially well adapted to date culture, meteorological data on the winter climate have not accumulated in sufficient quantity to make certain that the trees will flourish over winter. It is believed, therefore, that intending planters should await the results of the coming winter, rather than to plant blindly and then be disappointed in the future. The purpose of the article is to arrest the booming of date culture, but not in any way to stop the development of the industry along rational lines.

Making a cranberry bog, F. A. MAKEPEACE (*Country Gent., 69 (1904), No. 2693, p. 819*).—Detailed directions are given for making a cranberry bog. After the plants have been set it is about 4 years before they come into full bearing. Once established, a good bog should bear steadily for 10 to 12 years without doing much to it other than keeping it free from weeds and the ditches cleaned out. The average annual production of an acre of good bog is placed at 100 bbls. With the cranberry picker a skillful operator will average about 10 bbls. of fruit per day.

Trial shipment of grapes to England (*Jour. Dept. Agr. West Australia, 10 (1904), No. 1, pp. 24–27*).—Different varieties of grapes were shipped to England in a number of different packages. They arrived in England about 5 weeks after picking. All of the varieties had lost their bloom and fresh appearance, and the stalks had become discolored and somewhat shriveled.

The varieties which had been packed in cork dust arrived in decidedly the best condition, those packed in paper only did not look so well, and those packed without any cork dust or covering at all were in the worst condition. For carrying purposes, therefore, the cork dust is recommended as preferable to any of the methods

tried. The grapes brought low prices, and it is not believed that fruit of this quality could be made to pay.

Keeping late grapes on the vine (*Agr. Gaz. New South Wales, 15 (1904), No. 9, pp. 907, 908, figs. 2*).—It was found that if the whole vine, grapes and all, was covered with heavy bagging while in full leaf, the grapes could be preserved for a much longer time than when the bunches were cut off with a small portion of the cane and the stem inserted in a bottle of water. This method, however, was a failure in wet seasons because the fruit remained damp within the bags for so long that it rotted. It is believed, however, that if the upper portion of the bag is covered with rubberoid so that the fruit may be kept dry this trouble may be avoided.

Investigations on the development and composition of varieties of grapes cultivated in Abraou-Durso, G. Barberon and F. Changeant (*Ann. Soc. Agr. Sci. et Ind. Lyon, 8. ser., 1 (1903), pp. 97–159, dgms. 6*).—Abraou-Durso is a province of Russia bordering the northeast coast of the Black Sea. Considerable wine of good quality has been produced there within recent years, and the authors made an extensive study of the composition of the skins, pulp, seed, juice, etc., of a large number of these varieties, all of which is presented in an extensive series of tables.

The quantitative determination of organic phosphorus compounds in grape seeds and natural wine, J. Weirich and G. Ortlieb (*Arch. Pharm., 242 (1904), No. 2, pp. 138–143*).—The presence of lecithin, which has been found in seeds by a number of investigators, led the authors to investigate its presence in grape seeds and in natural wine. This was found in considerable quantities in the seeds of a variety of grapes from Thyra, and also in sweet wine of high alcohol content made from these grapes.

When the seeds were extracted at a temperature much above 50° C. the organic phosphorus compounds were destroyed. From the data secured in this experiment the authors draw the conclusion that, in the handling of wine, heating above this temperature may destroy the lecithin in it and thus decrease its value for consumption. In wines low in alcohol content a very small amount or perhaps no organic phosphorus compounds may be found.

The presence of lecithin in wine, A. Rosenstiehl (*Arch. Pharm., 242 (1904), No. 6, pp. 475–477*).—The author calls attention to the insufficient data upon which Weirich and Ortlieb (see above) based their work in determining the lecithin content of wine, and of certain other important factors which they failed to take into account.

Notes on rubber plants (*East Africa Quart., 1 (1904), No. 3, pp. 127–129*).—East Africa rubber is obtained primarily from the various Landolphia vines. These vines usually grow on good soil in damp or shaded situations and are found at elevations from sea level up to 8,000 ft. On account of its climbing habit, however, Landolphia is not well adapted to cultivation. The rubber from a number of species has been submitted to the Imperial Institute, London, and a valuation placed upon the product.

A valuable new almond (*California Cult., 23 (1904), No. 19, p. 462*).—The new almond described originated as a chance seedling by a Doctor Simmons, of Sacramento. It has a hard shell and is of large size and excellent flavor. It is claimed for it that it is so hardy as to withstand any ordinary frost. It has proved a certain bearer for a number of years, yielding each season a very heavy crop. If these claims are substantiated it will make a valuable addition to the list of almond varieties.

Chestnut culture, J. W. Kerr (*Rpt. Maryland State Hort. Soc., 5 (1902), pp. 34–38*).—Contrary to the general belief that chestnuts will not grow on limestone land, the author states that Japanese chestnuts are successful wherever corn can be grown. The Japanese variety is advised for market purposes. The trees should be set about 25 ft. apart, and when 7 or 8 years of age should produce about a bushel of nuts per tree. The trees should be planted on ground that can be cultivated in order to better control insect pests.

Trees and shrubs tested in Manitoba and the Northwest Territories, W. SAUNDERS (*Canada Cent. Expt. Farm Bul. 47, pp. 50, pls. 6*).—In this bulletin the results are given of a large number of trials of trees and shrubs grown at the experimental farms at Brandon, Manitoba, and at Indian Head in the Northwest Territories during the past 16 years. The matter contained is a summary of the data which have appeared in the various reports from these stations. The object in compiling the bulletin has been to present in convenient and condensed form an account of the hardiness and desirability of different trees and shrubs for ornamental purposes about the home. While the testing has been done at these 2 farms in western Canada it is believed that the results are applicable in the East, since plants hardy enough to endure the climate of the Northwest may be planted with assurance of success in any of the eastern parts of Canada.

Species of the following shrubs and trees have proved hardy in the Northwest: Juneberry, barberry, birch, Siberian pea tree (Caragana), hackberry, virgin's bower, dogwood, native hazelnut, cottoneaster, hawthorn, broom (Cytisus), Elæagnus, hop, honeysuckle (Lonicera), matrimony vine, Neillia, poplar, wild cherry including sand cherry, *Pyrus baccata*, *P. prunifolia*, American mountain ash, oak, buckthorn, sumach, native currants, gooseberries, raspberries, willows, Buffalo berry, Spiræa, lilac, elm, arrowwood (Viburnum), the grape (*Vitis vulpina*), balsam, spruce, and tamarack.

Species of the following plants have proved partially hardy, that is, they may be killed back to the ground, but spring up each season, or may be only partially killed back: Alder, birthwort (Aristolochia), southernwood (Artemisia), bittersweet, hydrangea, privet, moonseed, ironwood, Periploca, mock orange, roses, elder (Sambucus), linden (Tilia), and pine.

The following species failed: Maples, horse-chestnuts, tree of heaven (*Ailantus glandulosa*), Akebia, false indigo (*Amorpha fruticosa*), hornbeam (*Carpinus*), hickory, chestnut, catalpa, button bush, *Cercidiphyllum japonicum*, *Colutea arborescens*, Deutzia, weigelia, spindle tree, *Exochorda grandiflora*, beech, greenwood, honey locust, Kentucky coffee tree, walnut, butternut, mulberry, American plane tree or buttonwood, tamarisk, and *Salisburia adiantifolia.*

Native ornamental plants of New Mexico, E. O. WOOTON (*New Mexico Sta. Bul. 51, pp. 40, pls. 12*).—The author makes a plea for the use of native plants for shade and ornament about the homes in New Mexico, and gives descriptions of a large number of coniferous and deciduous trees, shrubs, vines, and other plants which may be used for these purposes, with directions for handling them.

Third annual convention of the Chrysanthemum Society of America (*Amer. Florist, 23 (1904), No. 858, pp. 597, 598*).—An account of the proceedings of the society at its meeting held in Boston, November 3 to 5. Score cards for judging commercial chrysanthemums and chrysanthemums for exhibition purposes were adopted. For commercial purposes the weighting of the different points was as follows: Color 20, form 15, fullness 10, stem 15, foliage 15, substance 15, size 10. For exhibition blooms color, stem, and foliage were given 10 points each; fullness, form, and depth 15 points each, and size 25 points.

The book of the iris, R. I. LYNCH (*London and New York: John Lane, 1904, pp. XII + 214, pls. 37*).—This is the twenty-first number in the series of handbooks of practical gardening, edited by H. Roberts. Part 1 gives a description of the structure of the flower and its natural history. Directions are given for the culture of the various irises. Chapters are included on hybrids and hybridizing, diseases, and insects. Part 2 is devoted to a classification and descriptions of the various species, with cultural notes under each species.

Injurious effects of manure, U. P. HEDRICK (*Amer. Florist, 23 (1904), No. 856, p. 530*).—The author calls attention to the injurious effects which sometimes follow a heavy application of manure to flower beds, due to the fumes of ammonia arising

from the manure. An instance is cited in which a large bed of asters and Shasta daisies was thus blighted within 12 hours after the manure was applied. In another case seedling honeysuckles were badly injured by an early fall application of stable compost.

Experiments in these two cases indicated "that the injurious effects of ammonia from compost could be counteracted by immediately wetting plants and manure, or by mixing a considerable quantity of dry earth with the manure to absorb the ammonia." The author considers it doubtful whether it is often necessary or profitable to apply sufficient quantities of manure to growing plants to thus injure them. An instance of injury from this cause to chrysanthemums in pots is noted and of a bed of lettuce under glass which suffered more or less from the same cause.

Experiments with lawn grasses, B. D. HALSTED and J. A. KELSEY (*New Jersey Stas. Rpt. 1903, pp. 492, 493*).—A report is given of the conditions of the grass plats, which have been maintained at the station since 1896. The condition of these plats, which are 9 in number, shows that the Rhode Island bent grass has maintained its rank as the most satisfactory species for lawn grasses for 4 years. The Kentucky blue grass is also very satisfactory, the other species proving less adapted to their surroundings, and the red top and perennial rye seem to be unsuited to their conditions.

FORESTRY.

Report of the committee on forestry, 1903, J. T. ROTHROCK (*Pennsylvania Dept. Agr. Rpt. 1903, pp. 509–513*).—It is claimed that the forestry policy of Pennsylvania is safely established, and for some time will be confined to an extension of what has already been begun. Work has been carried on in the propagation of forest seedlings and considerable transplanting of these seedlings has been done.

Attention is called to a recent law which authorizes the establishment of buildings for the purpose of training State foresters. The object of this school is to train men in any branch of forestry, and during the year 15 students were enrolled, who devoted half their time to study and the other half to forest work, which consisted in a considerable degree of patrolling the reserves to protect against fire, trespassing, etc. This is believed to be the first mounted State guard that any State possesses for its rural districts.

Forest thinning and its results, W. F. HUBBARD (*Forestry and Irrig., 10 (1904), No. 7, pp. 313–319, figs. 2*).—An account is given of some results of forest thinning, the illustrations of systematic thinnings being drawn from the forest belonging to the Forest Academy at Tharand and at the Austrian station in Mariabrunn. In the first case the stand was principally Scotch pine and in the second Austrian black pine. The stand of trees per acre, diameter, height, volume, etc., are given, showing not only the standing timber, but the amount removed from time to time.

Based upon these observations, the author draws some conclusions relative to forest thinning in this country, and he applies the classification to American conditions with some modifications. An illustration is given showing the proposed thinning of a 27-year-old stand of white pine.

Street forestry, F. SHONNARD (*Yonkers, New York: Department of Public Works, 1903, pp. 48, pls. 13*).—A report is given on the selection, planting, cultivation, and care of street shade trees, and particular attention is paid to the injuries to trees from electric and gas services.

An experiment is reported in which the author investigated the injurious effect of illuminating gas by introducing the gas at the rate of 1.07 cu. ft. per hour into a large pot containing a growing lemon tree. The effect of the gas on the foliage was noticeable on the third day, and on the eighth day the leaves were curling and dropping from all parts of the tree and sap was being exuded in a considerable quantity from the bark on its trunk and branches. At this time the gas was turned off, the tree

removed from the pot, and the gas-saturated soil washed from the roots. Similar tests are being carried on to determine the essential facts of gas injury to trees.

Forestry and close settlement, P. MacMahon (*Queensland Agr. Jour., 15 (1904), No. 2, pp. 599–603, figs. 4*).—An account is given of Australian forests in which the relation of forestry and population is discussed. With a total area of 2,945,991 sq. miles in Australia proper, there is a forest area of 150,000 sq. miles, amounting to about 5 per cent of the total area, while the extent of land that has been alienated or appropriated in various ways amounts to but little more than 6 per cent of the total area. If these figures be continued to include all of Australasia, the proportion is increased about 1 per cent.

A discussion is given of the forest area in relation to population of different portions of Europe, and statements made regarding the distribution of forest species, number of trees grown per acre under different systems of management, etc.

Forest fires (*Forestry and Irrig., 10 (1904), No. 9, pp. 433, 434*).—During the month of August disastrous forest fires occurred in Montana, Oregon, and Washington, the long-continued drought coupled with the very hot summer having made conditions very favorable for fires. The extent of the fires, cause where known, and loss are shown. During the same period extensive fires are reported from various parts of British Columbia, Newfoundland, and elsewhere, the fires in British Columbia being pronounced the most destructive since 1896.

Forest fires in Maine (*Forestry and Irrig., 10 (1904), No. 8, pp. 376, 377*).—An outline is given of investigations which have been carried on by the Bureau of Forestry in cooperation with the State of Maine in studying the causes and results and means of prevention of forest fires.

Ornamental and useful subtropical trees, T. R. Sim (*Natal Agr. Jour. and Min. Rec., 7 (1904), No. 8, pp. 776–779, pls. 6*).—Descriptions are given of a few tropical and subtropical trees which have proved adapted to the coast district of Natal and which are believed to be worthy of more extended cultivation than they now receive. Among the species described are the date palm, banyan, cocoanut palm, mangosteen, screw pine, rubber trees, flamboyant or royal Poinciana, etc.

Reforesting mountain slopes, T. P. Lukens (*Water and Forest, 4 (1904), No. 3, pp. 1–4, figs. 3*).—The work which is contemplated by the Bureau of Forestry of this Department in reforesting portions of southern California is described. Notes are given from various sources comparing the value of forests as a protective agent against erosion; comparisons made of the run-off of forested and nonforested lands, and the various efforts that have been made to reforest the region about San Bernardino and Los Angeles, Cal., are described.

An object lesson in reforestation, A. W. Tourgée (*Forestry and Irrig., 10 (1904), No. 8, pp. 354–361, figs. 5*).—An account is given of the methods by which the Landes and adjoining districts of France have been restocked with the maritime pine. Nearly 700,000 acres of forest are now under cultivation which were formerly barren wastes or sand dunes.

Indirect influence of forests, H. Lafosse (*Ann. Sci. Agron., 2. ser., 1902–3, II, No. 2, pp. 288–312*).—Some of the indirect influences of forests, such as effect on temperature, as wind-breaks, as means of protecting water supply, mechanical effects of roots on rocks and soils, the effect on health, etc., are discussed.

Forest planting in western Kansas, R. S. Kellogg (*Forestry and Irrig., 10 (1904), No. 7, pp. 321–326*).—The forest planting which was begun along the border of the Great Plains a good many years ago is said by the author to have resulted in abundant success. The most extensive early plantings were on the so-called timber claims, which were generally failures on account of the selection of improper species and neglect. A close examination of the results obtained leaves little room for doubting the success of forest planting in western Kansas if the species are intelligently selected and properly cared for.

Notes are given on the choice of location, methods of planting, cultivation, etc. For upland planting under ordinary conditions the author recommends the honey locust, Osage orange, Russian mulberry, and red cedar, followed by white elm, green ash, hackberry, and Scotch and Austrian pines, where these species can be properly cared for. For valley plantings, where the roots will eventually get the benefit of permanent water, all of the upland species are said to be excellent, and in many localities cottonwood, box elder, soft maple, black walnut, and hardy catalpa may be added. Under favorable conditions, where growth is rapid, Osage orange, black locust, Russian mulberry, and hardy catalpa may be profitably planted for commercial returns.

Forestry in the Michigan State Agricultural College (*Forestry and Irrig., 10 (1904), No. 7, pp. 326–329, figs. 3*).—An outline is given of the course of forestry, which was put in operation at the Michigan Agricultural College September, 1902. The forestry course extends over 4 years and the schedule of subjects pursued in the last 2 years is given in detail.

Experimental forest in Minnesota, C. C. ANDREWS (*Forestry and Irrig., 10 (1904), No. 8, pp. 379, 380*).—A description is given of the experimental forest of 20,000 acres which the State of Minnesota has set aside as an experimental forest. This consists of third and fourth rate land and has been selected on the Vermillion Range, about 12 miles from the town of Ely.

Forest-tree seed collecting in New Mexico, W. H. MAST (*Forestry and Irrig., 10 (1904), No. 7, pp. 309–312*).—An account is given of the author's experience in collecting forest-tree seed, principally western yellow pine, in New Mexico. The various tree seeds selected were piñon pine, red and white fir, limber pine, blue spruce, western yellow pine, and one-seed juniper. The methods for collecting each of these species of seed are described at some length, and a table is given which shows the amount of seed collected and the cost per pound of each species. The cost ranged from 23 cts. to $1.47 per pound.

Forest conditions in western Wisconsin, L. H. PAMMEL (*Forestry and Irrig., 10 (1904), No. 9, pp. 421–426, figs. 3*).—The early history of the forests in western Wisconsin is traced, and statements given regarding their present condition. The author divides the region into different formations, describing the characteristic soils and the more important species occurring in the different formations, and also the important shrub and herbaceous plants associated with the different forest trees. The formations described are the river formation, sandy uplands, valley formation, ridge formation, and tamarack formation.

The black wattle (Acacia decurrens), E. HUTCHINS (*Agr. Jour. Cape Good Hope, 25 (1904), No. 3, pp. 277–280*).—An account is given of the various attempts which have been made to cultivate the black wattle in Cape Colony and elsewhere. While it has been frequently claimed that the black wattle will grow in the poorest soils, according to the author experiments have shown that while the soil may be deficient in plant food it must be moist and open. A number of plantations of this tree have been made in different parts of Cape Colony and where the rainfall has been sufficient the growth has been very satisfactory. Where rainfall is not abundant but irrigation can be followed, equal satisfaction has been experienced.

The author concludes with statements taken from an account of black wattle cultivation in Natal, in which it is stated that in 1903 there were 25,000 acres of black wattle in cultivation. The cultivation of this tree was first begun about 20 years ago, and the production of bark now amounts to nearly $500,000 annually.

The poplars, L. BRETON-BONNARD (*Le peuplier. Paris: Lucien Laveur, 1903, pp. VIII+213, pls. 2, figs. 97*).—The poplar, according to the author, is next to the oak the most valuable tree for general cultivation in France. The monograph which he has presented gives an account of the history of these trees and their distribution,

and describes their culture, uses, diseases and insect injuries and their remedies, exploitation, products, etc.

After a general discussion of the botanical characters of the genus, descriptions are given of about 20 species and varieties which are either indigenous or introduced in France. Chapters are given on the reproduction, planting, culture, etc., and special attention paid to numerous fungus and insect enemies of the tree. The volume concludes with accounts of the various products and their utilization, and with directions for the evaluation of standing timber.

The study of the red gum (*Forestry and Irrig., 10 (1904), No. 7, pp. 333–335*).—An outline is given of recent investigations of the Bureau of Forestry of this Department on the value and utilization of the red gum. The rapid growth, occupation of swamp lands, and immunity from fires attracted attention to this tree as a means of continuing the lumber supply for certain uses. In spite of its abundance, this tree has been slow to be recognized of commercial importance, largely on account of the extent to which it warps and stains in seasoning. The Bureau of Forestry has been carrying on investigations at its timber-testing laboratory to determine more fully the value of this timber in comparison with higher-priced material.

The results obtained so far show that the red gum may serve for carriage and wagon wood stock in place of hickory, and it is believed that experiments will determine methods of seasoning which will overcome the warping and twisting that result from the ordinary drying of the timber. Field studies are being carried on in a number of localities, and a careful study of second growth and stand per acre will be made in the hopes of securing data that can be made the basis of recommendations for the proper management of hard-wood bottom lands.

The water elm, J. Jensen (*Forestry and Irrig., 10 (1904), No. 8, p. 384*).—A brief account is given of the occurrence in Michigan of the water elm (*Zelkova acuminata*), a species indigenous to the mountain region of Japan. This tree was introduced in 1879, a number of specimens being planted at the South Haven Substation. The largest tree measures 3 ft. 10 in. in circumference 3 ft. from the ground and is more than 20 ft. in height. This rate of growth for a 24-year-old tree is believed to show the possibilities of this species of forest tree where climatic and soil conditions are favorable to its growth. The larger specimens have already ripened seeds as is evidenced by numerous seedlings observed in hedges near by.

Camp life at the Yale Summer School of Forestry, Q. R. Craft (*Forestry and Irrig., 10 (1904), No. 9, pp. 427–431, figs. 3*).—A description is given of the location of the Yale Summer School of Forestry at Milford, Pa.; its advantages pointed out, and brief outlines of the courses and methods of instruction given.

SEEDS—WEEDS.

The biology of the seed of species of Inga, A. Borzi (*Rend. Roy. Accad. Lincei, 1903, pp. 10; abs. in Bot. Centbl., 95 (1904), No. 22, pp. 578, 579*).—An account is given of some observations on the seed of a number of species of Inga, which the author states are naked embryos without the usual seed coats.

The covering of the seed consists of a white sugary pulp which easily separates from the black seed. The seed enveloped in this pulp is carried in the long pods and is scattered more or less by birds seeking the pulp. The naked embryos are able to retain their germinative power for a considerable time and by special physiological and biological adaptations are protected against excessive radiation, transpiration, etc. The external portions of the embryos are provided with thickened cuticularized tissues containing tannin and anthocyanin. The aeration of the seed is secured by a mechanism which corresponds to the micropyle of ordinary seeds. A number of other important analogies between this peculiar seed and normal seeds are pointed out.

Rules and apparatus for seed testing (*U. S. Dept. Agr., Office of Experiment Stations Circ. 34, rev. ed., pp. 24, figs. 11*).—This is a revised edition of Circular 34 (E. S. R., 9, p. 143), which describes the rules and apparatus for seed testing, the present edition giving special attention to the description of improved apparatus, more specific directions regarding sampling, and more definite information regarding the seed bed, temperature, duration of test, etc. This circular is the work of a committee appointed by the Association of American Agricultural Colleges and Experiment Stations at its meeting in November, 1903.

Experiments with seeds and seedlings, B. D. HALSTED and J. A. KELSEY (*New Jersey Stas. Rpt. 1903, pp. 510–517*).—During the period covered by this report experiments were made with squash and other seeds to determine the time required for the germination of various cucurbitaceous seeds. In connection with the germination tests a study was made of the method by which the thick seed coats are removed and the young plant emerges from its covering. The effect of mutilating squash seeds and of the mutilation of corn on germination is reported upon, and a brief account given of the germination of Martynia or Unicorn plant seed.

Experiments with weeds, B. D. HALSTED and J. A. KELSEY (*New Jersey Stas. Rpt. 1903, pp. 498–504*).—A report is given on the condition of the various weeds in the weed belt which has been maintained for 7 years, and the relative rank of the different species is practically the same as noted in the previous report (E. S. R., 15, p. 159).

Extended notes are given on a species of Galensoga, which has become a troublesome weed in New Jersey, and an account is given of the black nightshade (*Solanum nigrum*) and notes given on its reputed poisonous properties. An account is also given of the broom rape (*Orobanche ramosa*) as a parasite on tomatoes grown in the greenhouse.

Report of the botanist, 1903, W. A. BUCKHOUT (*Pennsylvania Dept. Agr. Rpt. 1903, pp. 587–590*).—A description is given of a number of weeds which have become troublesome, among the more persistent ones being the horse nettle, hop clover, sheep sorrel, field cress, and *Galinsoga parviflora*. This weed, which has been recently introduced, probably from South America, seems to be slowly spreading in moist ground throughout the State. A suggestion is made for eradication of weeds in fields, lawns, etc., and brief notes given on a number of plant diseases.

Prickly pear extermination (*Natal Agr. Jour. and Min. Rec., 7 (1904), No. 7, pp. 716–718*).—A description is given of what is called the Queensland system of prickly pear extermination, which consists of the use of a sodium-arsenate spray made by combining 4 lbs. of white arsenic and 3 lbs. of washing soda in 1 gal. of water. After boiling for half an hour the solution is used at the rate of 5 to 8 oz. added to 1 gal. of water.

The destruction of wild mustard, ROUSSILLE (*Bul. Soc. Nat. Agr. France, 64 (1904), No. 6, pp. 451, 452*).—A brief account is given of a comparative test of power and hand spraying apparatus for use in combating the wild mustard. The herbicide used in each case was composed of 4 kg. copper nitrate to 100 liters of water. This was applied at the rate of from 800 to 1,000 liters per hectare, and was used successfully for the destruction of the weed without any injury to the crop, which in this case was oats.

All the forms of apparatus tested proved satisfactory, particularly the hand machines, which were adapted to use on a limited area. Iron sulphate, when used at the rate of 300 kg. mixed with 200 kg. of plaster, applied to a hectare, gave very unsatisfactory results.

Destruction of wild mustard, TRIBOULET, ROMMATIN, and SAINT-QUENTIN (*Bul. Soc. Nat. Agr. France, 64 (1904), No. 6, pp. 461–466*).—The results of experiments with copper and iron sulphate solutions, and the use of the same in powdered form for the destruction of wild mustard and wild radish in growing crops, are given.

DISEASES OF PLANTS.

Some bacterial diseases of plants prevalent in Ontario, F. C. HARRISON and B. BARLOW (*Ontario Agr. Col. and Expt. Farm Bul. 136, pp. 20, figs. 12*).—An account is given of the fire or twig blight due to *Bacillus amylovorus*, a bacterial disease of beans due to *Pseudomonas phaseoli*, a soft rot of white turnips, cauliflowers, and cabbages, a rot of Swedish or yellow turnips, and a bacterial rot of stored celery.

The fire or twig blight, which affects pear and apple orchards, is described at considerable length, and notes given on the distribution of the disease, losses attributed to it, symptoms of the disease, life history of the organism causing it, and suggestions for its prevention.

The bacterial disease of beans described affects the wax beans grown largely for canning purposes. The disease begins at the margin of the leaf, or where it has been injured by insects, winds, or hail, and gradually a yellow spot appears, which spreads slowly, the diseased tissues finally becoming brown and almost black. Inoculation experiments have shown that the cause of this trouble is the organism *Pseudomonas phaseoli;* and for its prevention it is recommended that healthy seeds be used in planting, to be treated as a precautionary measure with water heated to 122° F. for 10 minutes, or soaked for a short time in a corrosive sublimate solution, 1 part to 1,000 of water. When the disease has made itself apparent the cultivation of beans in that soil should be abandoned for several years, as the organism is believed to be able to remain in the soil for some time.

The soft rot of white turnips, cauliflowers, cabbages, etc., is attributed to the organism *Bacillus oleraceæ*. This organism produces in these plants a sof. rot which causes considerable loss in the fields. A more extended account of this disease is given elsewhere (see p. 480).

The soft rot of Swedish or yellow turnips is caused by an organism quite similar to the one causing the soft rot of white turnips, but is subject to slightly different conditions. For the prevention of this disease it is recommended that the roots be thoroughly ripened and cured before being placed in storage. In order to secure this result the harvesting of the root crop should be delayed as long as possible, and after pulling the roots they should be allowed to dry before being stored.

A brief description is given of a rot of stored celery which was observed at the agricultural college during the winter of 1903–4. From a number of the decayed stems cultures were made and 2 varieties of *Pseudomonas fluorescens* were isolated. One variety causes the stems to become brownish or amber colored in rotting, while the other shows a greenish-blue color. Fresh celery plants inoculated with the organism after a few days showed the presence of the rot, indicating that these organisms were its cause. As precautionary measures for preventing the rot the authors recommend that celery should be packed with the roots in clean soil, which should be kept moist but not wet, and the atmosphere of the soil or storage room should be kept at a uniformly low temperature, but little above the freezing point.

Investigations at the station of plant pathology, G. DELACROIX (*Bul. Soc. Mycol. France, 19 (1903), Nos. 2, pp. 128–145; 4, pp. 342–355*).—Notes are given on a number of investigations carried on at the laboratory under the direction of the author. Among them are discussed the conidial form of the black-rot fungus, an apple-tree canker due to *Sphæropsis malorum*, a monstrous form of ergot, a disease of guavas caused by *Glœosporium psidii*, n. sp., a mildew-like disease of mulberries caused by *Ocularīopsis ulmorica*, n. sp., and the parasitism of *Dothichiza populea* on several species of poplars.

Letters on diseases of plants, N. A. COBB (*Dept. Agr. New South Wales, Misc. Pub. 666, 2. ser., pp. 133, pls. 11, figs. 132*).—This is a compilation, with additions and emendations, of papers by the author on this subject, which were published from time to time in the *Agricultural Gazette of New South Wales.*

The West Indian anthracnose of cotton, L. LEWTON-BRAIN (*West Indian Bul., 5 (1904), No. 2, pp. 178–194, figs. 7*).—The presence of an anthracnose of cotton has been long known in the West Indies and has been frequently identified as identical with the cotton anthracnose of the United States. Recent investigations of the author have shown the occurrence of this disease over quite a considerable portion of the British West Indies, but it so far does not seem to have occasioned any very great destruction of the cotton bolls. The symptoms of the disease are described, as well as the results of cultures and artificial inoculations with the fungus.

Studies of the organism have led the author to conclude that while not specifically distinct, the form occurring in the West Indies differs so constantly in some of its spore characters as to warrant its description as a distinct variety, the name *Colletotrichum gossypii barbadense*, n. var., being given it. Suggestions are given for combating the fungus, which include the burning of all refuse about cotton fields, treatment of seed with a week solution of corrosive sublimate, selection of seed from healthy plants, etc.

Streptothrix as a cause of musty oats, D. BROCQ-ROUSSEU (*Rev. Gén. Bot., 16 (1904), No. 186, pp. 219-230, pl. 1*).—The author reports having frequently noticed oats which exhaled a marked musty odor, sometimes to such an extent that animals would refuse to eat the grain, and serious loss was occasioned.

A study was made of a number of varieties and from the molded specimens a number of fungi and bacteria were isolated, but the only organism occurring uniformly throughout all the samples was a species of Streptothrix. The characters of this fungus as shown in various cultural media are described, and studies with cultures on sound oats showed the possibility of its causing the moldy odor. Comparisons are made between this and the other known species of Streptothrix, and while it approaches most nearly *S. fœrsteri*, still it can not be definitely identified with that species.

As a practical result of examination, the author found it was possible to prevent its infesting sound oats if the grain could be kept in a dry condition and not mixed with any that was musty, and that musty oats would lose this odor if heated for half an hour at a temperature of 80° C.

The study of potato rot, G. DELACROIX (*Ann. Inst. Nat. Agron., 2. ser., 3 (1904), No. 1, pp. 37–74, figs. 2*).—An account is given of an unusual outbreak of potato rot near Paris during the autumn of 1903. The atmospheric conditions were especially favorable for the development of the fungus and the losses caused by it were very great. An extended discussion of the methods of infection is given, as well as notes on the life history of the organism. Other diseases due to fungi and bacteria were observed, but to the Phytophthora is attributed all the serious injury.

In studying the disease marked differences in infection were noticed for different varieties, and differences of soil, fertilizer, moisture, etc., were found to influence the amount of disease in any particular variety. An excess of nitrogen was found to favor the activity of the fungus, while potatoes grown with potash and phosphoric acid fertilizers were less affected. Depth of planting is said to exert an influence on the spread of the disease, the conidia of the fungus seeming to be unable to penetrate the soil to a depth of more than 10 cm. The use of fungicides during the growing season is recommended, and care in the selection and wintering of seed tubers is advised.

The leaf brown of the potato, J. J. VAŇHA (*Naturw. Ztschr. Land- u. Forstw., 2 (1904), No. 3, pp. 113–127, pls. 6; abs. in Bot. Centbl., 96 (1904), No. 29, p. 67*).—A description is given of a disease of potatoes which is reported as having been common in Bohemia, northern Germany, Scandinavia, and elsewhere. In many particulars it resembles the potato rot caused by Phytophthora, but careful examination showed it to vary in a number of particulars, and the cause of the leaf spot to be *Sporidesmium solani varians*, n. var.

The effect of the fungus on the host plant, as well as its character as shown in pure cultures, is described. For the prevention of the disease the author recommends spraying the potatoes throughout the season with Bordeaux mixture at intervals of 2 or 3 weeks. After the potato harvest it is suggested that the tops should be collected and burned, and attention paid to the use of fertilizers and manures. Deep plowing of the potato field after harvest is suggested as a beneficial practice; and potatoes should not be continued in the same field for any long period of time, since the fungus is liable to become established in the soil, where it is able to pass the winter.

Some diseases of the potato, G. MASSEE (*Queensland Agr. Jour., 15 (1904), No. 2, pp. 605–607*).—A summary is given of an article published by the author in *Gardeners' Chronicle* relating to some of the diseases of the potato. Among those described are the potato rot (*Phytophthora infestans*), winter rot (*Nectria solani*), black scab (*Œdomyces leproides*), bacterial disease (*Bacillus solanacearum*), and potato scab (*Sorosporium scabies*).

Treatment of potatoes with fungicides, F. PARISOT (*Jour. Agr. Prat., n. ser., 8 (1904), No. 34, pp. 234, 235*).—In a series of experiments carried on at Rennes 4 varieties of potato were grown in different lots, one lot in each case being treated with Burgundy mixture, containing 2 per cent copper sulphate, and the others remaining as checks.

The results of the treatment showed that in the case of 3 varieties there was a difference in favor of the treated plants, varying from 7 to 50 per cent, while with the fourth variety there was a loss of 24 per cent. It appears from these investigations that spraying early or semiearly varieties is attended with good results, but when the variety of potato grown is a very late one the author's experiments showed a positive loss. These results are in line with those quoted from experiments by Aimé Girard, who found that very late varieties were less influenced by spraying than medium or early varieties.

Sugar-beet diseases, W. H. HUTT (*Utah Sta. Rpt. 1903, pp. XXII–XXVI*).—An account is given of cooperative experiments arranged with this Department in which the effect of different fertilizers in checking sugar-beet diseases was investigated. The disease in question was first noticed in 1902 and seemed to be very destructive wherever observed.

On examination of the fields a few beets were found which seemed to have resisted the disease, and these were placed in a silo with the expectation of raising strains of beets which might be immune to the disease. The rot, however, continued throughout the winter, and of several bushels which were stored but one beet remained to bear seed. As the disease did not appear at all during 1903 the experiment resolved itself simply into a test of the value of different fertilizers for raising beets.

The yellowing of sugar beets, G. DELACROIX (*Compt. Rend. Acad. Sci. Paris, 137 (1903), No. 21, pp. 871, 872; extr. from Sucr. Indig. et Coloniale, 62 (1903), No. 22, pp. 13*).—A description is given of a bacterial disease of beets which has been under observation for some time. The author has isolated the organism causing the disease and studied its characters, and he proposes for it the name *Bacillus tabificans*. The distribution of the disease, its characteristics, and methods of attack are described and notes given on experiments for combating it.

As a preventive treatment the author recommends at least a 3-years' rotation of crops, the use of no seed that is 4 years or more old, the careful exclusion of all volunteer crops on fields where beets have been cultivated, and care in the application of manures that none should come from animals fed with diseased beet leaves.

A disease of asparagus, G. DELACROIX (*Extr. from Bul. Mens. Off. Renseignements Agr., 1903, pp. 6*).—The author describes a disease of asparagus which is attributed to the well-known fungus *Rhizoctonia violacea*.

Vitality of the cabbage black-rot germ on cabbage seed, H. A. HARDING, F. C. STEWART, and M. J. PRUCHA (*New York State Sta. Bul. 251, pp. 177–194, pl. 1*).—The results of investigations on the vitality of the cabbage black-rot germ on cabbage seed are given, a preliminary note on which has already been published (E. S. R., 16, p. 170). The authors found that the black-rot organism (*Pseudomonas campestris*) is capable of remaining in a living form on the seed for a considerable time, and the conditions under which cabbage seed is produced make it possible for the organism to be carried over from crop to crop. Cabbages intended for seed are usually placed in shallow trenches at the approach of freezing weather and covered with a few inches of soil. Here they are frozen in and remain until spring. In the spring the plants frequently show the effect of the organism, and observations made in the field show that seed plants are often more or less attacked and the organisms are found adhering to the seed. The bacteria have been isolated and experiments show that cultures of organisms isolated from the seeds are capable of producing a typical form of the black rot.

A careful study of the conditions attending the growth and harvesting of cabbage seed has led the authors to the belief that practically all the cabbage seed produced on Long Island is infested to some extent. Experiments have shown that the germs are able to live upon the dry seed and retain their vitality from 8½ to 11 months.

Experiments with seed disinfection showed that soaking the seed in a solution of corrosive sublimate or of formaldehyde would destroy the organisms without seriously affecting the germination of the seed. This treatment is recommended, but it must be kept in mind that it is only a preventive treatment and that, if plants are set in infected soils, the treatment will have but little value.

A bacterial disease of cauliflower and allied plants, F. C. HARRISON (*Ontario Agr. Col. and Expt. Farm Bul. 137, pp. 32, figs. 12*).—During the summer of 1901 in the vicinity of Guelph complaint was made of a rot of cauliflowers, and shortly afterwards the same disease was noticed in a number of other localities. Later it was found attacking varieties of turnips, the loss in some cases reaching as high as 64 per cent. The disease was constantly associated with an organism which was isolated, and inoculation experiments made with it showed that it would produce the characteristic rot.

The morphological characters of the organism, which is designated as *Bacillus oleraceæ*, are given, as well as the results of an extended series of inoculation experiments, which showed the susceptibility of a number of allied plants to attacks of this bacillus. The cultural characters of the organism, as shown on a large number of media, are described and the conditions affecting the spread of the disease are stated. Warm weather, combined with excessive moisture, rankness of growth, abundance of insect pests, injuries from planting, all contribute to the spread of the disease. Marked differences are noted in the susceptibility of varieties to the disease, and a list is given of varieties of turnips in which the percentage of rotted roots is shown for different varieties.

The sleepy disease of tomatoes (*Jour. Bd. Agr. [London], 11 (1904), No. 5, pp. 300–302*).—A description is given of a disease of tomatoes due to *Fusarium lycopersici*. The fungus causing this disease flourishes in the soil and is known by 3 distinct stages, which are briefly described. For treatment it is suggested that all diseased plants should be removed and burned and, where possible, the soil should be sterilized. The use of lime on infected soils is recommended, and also that great care be taken in selecting healthy plants and securing plenty of air, light, and room for their development.

Black spot of the apple, D. MCALPINE (*Dept. Agr., Victoria, Bul. 17, pp. 32, pls. 19, figs. 2*).—This is said to be a revised edition of a previous publication, noted elsewhere (E. S. R., 14, p. 775).

The disease in question is due to *Fusicladium dendriticum*, and an account is given

of its appearance in Australia, the susceptibility of varieties, symptoms and time of attack, losses due to the fungus, conditions favoring the disease, etc. In addition, the results of experiments in spraying for the control of this disease are given, and directions for the preparation and application of fungicides. The experiments have shown that this disease may be readily prevented by the thorough use of Bordeaux mixture, for which purpose a 6-4-40 formula is preferred.

The witches' broom of plums, C. Bossu (*Rec. Biol. Expt. Appl. Agr., 1 (1901–1903), pp. 387–390; abs. in Bot. Centbl., 96 (1904), No. 34, p. 186*).—A description is given of the witches' broom of plums, due to the fungus *Exoascus institiæ*. The malformation described seemed to be restricted to plums of the Damson type, and the mycelium is readily traced through the bark parenchyma, phloëm, xylem, and medullary rays.

For combating the disease it is recommended that the witches' brooms should be cut out, the twigs being cut back at least 50 cm. below the malformations. The wounds should be treated with a solution of iron sulphate, after which they should be covered with coal tar. As a means of preventing the spread of the disease the trees should be sprayed several times with Bordeaux mixture.

The coffee disease in Oaxaca, A. L. Herrera (*Bol. Com. Par. Agr., 2 (1904), No. 5, pp. 207–276, pls. 8*).—A summary of information regarding a rust of coffee due to the fungus *Stilbella flavida*. The information given is derived from various sources, as well as the investigations of the commission that were carried on in Oaxaca and other parts of Mexico. In addition to the above-named fungus other species are considered. The value of Bordeaux mixture for the control of leaf diseases of this character is pointed out.

Progress of cranberry spraying experiments, C. L. Shear (*Proc. Amer. Cranberry Growers' Assoc., 35 (1904), pp. 6–8*).—This is a report on the experiments which are being conducted by the Bureau of Plant Industry of this Department for the prevention of cranberry scald or rot, by the use of Bordeaux mixture. At the time the report was made the indications were that from 75 to 90 per cent of the fruit on the sprayed plats was free from rot.

In an experiment reported by E. H. Durell, acting under the direction of Mr. Shear, a small bog of about 3 acres was overflowed June 6. As the water entered the bog about 20 lbs. of sulphate of copper per acre was dissolved in it. Up to the time of the report the bog showed an unusual absence of rot, indicating that the treatment had been effective. The treatment killed the fish in the stream.

Two new grape pests in Hungary, G. de Istvánffi (*Ann. Inst. Cent. Ampélol. Roy. Hongrois, 3 (1904), No. 1, pp. 55, pls. 3, figs. 15*).—The author describes 2 new parasites of the grape, the stinkhorn fungus (*Ithyphallus* [*Phallus*] *impudicus*) and an acarid (*Cœpophagus echinopus*). Both attack the roots of the grapevines, causing a very considerable loss.

The stinkhorn fungus has usually been considered as a saprophyte, but its frequent occurrence in many vineyards and on numerous varieties of grapes has led the author to conclude that the fungus has acquired a parasitic habit. Thus far the fungus has been found only on vines grown in sandy soils, and in Hungary it has 2 distinct periods of development, the aerial forms appearing in May and later toward the end of August, continuing until late in the autumn. The habit of the fungus, methods of growth and attack, effect produced on the host plant, etc., are described, and for its prevention burning infested vines and the fruiting bodies of the fungus wherever found, watering about the vines with a solution of calcium bisulphid, together with a renewal of the soil about the vines, are recommended.

In addition to grapes the fungus is known to attack the roots of the black locust, honey locust, and other plants. The mite mentioned is briefly described and notes given on its distribution, habits, etc.

The brunissure of grapes, L. RAVAZ (*Ann. Ecole Nat. Agr. Montpellier, n. ser., 3 (1903), No. 2, pp. 145–156; 3 (1904), Nos. 3, pp. 175–251; 4, pp. 286–327, pls. 2, figs. 41*).—This is an extended account of investigations by the author on the cause, nature, and prevention of brunissure, preliminary statements regarding which have been noted elsewhere (E. S. R., 15, p. 591; 16, p. 272).

The history of the disease and various theories regarding its causes are reviewed, and the author's experiments are described at length. As previously stated, the author claims that this disease is not of parasitic origin, but is due to an impoverished condition brought about by overbearing or other causes. The author states that neither scale insects nor mites can cause it, and that *Plasmodiophora vitis* and *Pseudocommis vitis* of various authors are not fungi but conditions in which there is a disintegration of the chloroleucites and cell contents.

In addition to overbearing, the presence of mildews, black rot, and other fungi, by weakening the plant, may favor the appearance of brunissure. Pruning, fertilizing, cultivating, etc., by increasing the vigor of the vines, tend to protect them from disease. As a rule, young vines are more subject to the disease than older ones.

Notes on the gray rot, E. OUSTRI (*Prog. Agr. et Vit. (Ed. L'Est), 25 (1904), No. 29, p. 64, pl. 1*).—A brief description is given of the gray rot of grapes caused by *Botrytis cinerea;* and for its prevention the author recommends the application to the vines of a mixture of hydraulic lime 65 kg., precipitated sulphur 25 kg., and sublimed sulphur 10 kg. This mixture is said to have given excellent results in combating the fungus. It is economical and easy of application.

Development of the black-rot fungus, P. VIALA and P. PACOTTET (*Rev. Vit., 22 (1904), Nos. 552, pp. 33–36; 553, pp. 61–64; 554, pp. 89–92, fig. 1*).—The results of an extended series of investigations on the development of the black-rot fungus (*Guignardi [Læstadia] bidwellii*) are given. The methods of obtaining and propagating the cultures are described at length, and the effect of temperature, moisture, toxic agents, etc., on the growth and reproduction of the organism are fully noted.

Notes on the black rot, A. PRUNET (*Rev. Vit., 22 (1904), No. 561, pp. 289–291*).—The dependence of the fungus on the spring rains for the spread of the primary invasion is pointed out, and a discussion given of the bearing this has on the proper application of fungicides for the control of the disease. The primary invasion is confined principally to the leaves and makes its appearance early in the season. In the secondary invasion the fungus attacks the fruit. The vines which escaped the primary invasion are less subject to secondary attacks.

Macrophoma reniformis on grapes in Algeria, L. TRABUT (*Rev. Vit., 22 (1904), No. 558, p. 217*).—The author reports the occurrence of *Macrophoma reniformis* on Chasselas grapes in the markets of Algiers. This fungus has been reported in Italy, Russia, and various other places, but has not hitherto been recognized as occurring in Algerian vineyards.

Culture and development of the grape anthracnose fungus, P. VIALA and P. PACOTTET (*Rev. Vit., 22 (1904), Nos. 555, pp. 117–121; 556, pp. 145–150, figs. 10*).—The authors have isolated and studied the fungus (*Sphaceloma ampelinum*) causing the grape anthracnose, and give the results of their studies. It is claimed that the fungus, which has been known only from its conidial stage, is improperly classified, and it is referred to as a new genus and the name *Manginia ampelina* given it.

Puccinia polygoni-amphibii and Æcidium sanguinolentum, H. VANDERYST (*Rev. Gén. Agron. [Louvain], 13 (1904), No. 5, pp. 219–222*).—Studies of the rusts commonly found on various species of geranium and Polygonum have convinced the author that *Æcidium sanguinolentum* and *Puccinia polygoni-amphibii* are different forms of the same heterœcious fungus.

A new species of Thielaviopsis, L. PETRI (*Nuovo Gior. Bot. Ital., 1903, No. 4, pp. 582–584; abs. in Bot. Centbl., 95 (1904), No. 22, p. 592*).—A description is given of a new species of Thielaviopsis, which has been observed by the author on the roots

of Podocarpus. The fungus, which greatly resembles *T. ethacetica*, the cause of the so-called pineapple disease of sugar cane, has been given the name *T. podocarpi*. The organism has been cultivated on a number of different media and its chief characteristics are described.

Report of the botanist, 1902, W. A. Buckhout (*Pennsylvania Dept. Agr. Rpt. 1903, pp. 220–222*).—The principal inquiries of the botanist during the year reported upon were in relation to weeds and weed eradication.

In addition a number of plant diseases were investigated, and a brief account is given of a disease of ornamental white birch, which was accompanied by an abundant exudation of red or brown slime that had a very offensive odor. Diseases of this kind have been known in Europe, but they seem to be imperfectly understood. They appear to be the result of some mechanical injury, but sometimes occur where there is apparently no definite cause. Without having more information the author did not feel warranted in making recommendations for treatment.

Plant diseases in Denmark, 1903, E. Rostrup (*Tidsskr. Landbr. Planteavl, 11 (1904), pp. 395–424*).—The report contains the usual review of plant diseases appearing in Denmark during the year 1903.

Plant pathological experimental work and its aims, F. K. Ravn (*Tidsskr. Landbr. Planteavl, 11 (1904), pp. 376–394*).—An address delivered before the Royal Agricultural Society of Denmark, with discussion.

ENTOMOLOGY.

Report of the entomologist, J. B. Smith (*New Jersey Stas. Rpt. 1903, pp. 557–659, figs. 32*).—A marked decrease in the numbers of insects injurious to asparagus was noted during the year under report. An account is presented of various plant lice injurious to shade trees, ornamental plants, fruits, and garden vegetables. The San José scale still requires more time and energy for its control than all other orchard pests combined. While the insect occurs on many forest trees the author has not observed serious infestations on such trees. In one locality the San José scale was attacked by the fungus *Sphærostilbe coccophila*. Notes are also presented on a number of other scale insects, leaf hoppers, ladybirds, codling moth, nut weevils, household insects, and pests of potato, tomato, and cabbage.

The author states that the Chinese mantid has apparently become well established in various parts of New Jersey, but is nowhere very numerous. The Chinese ladybird still maintains itself in small numbers, but it can not yet be stated definitely that it will thrive under outdoor conditions. One serious parasite of this insect was noted and was identified as *Syntomosphyrum esurus*. Kerosene emulsion with milk or soap is no longer used extensively. Crude oil is still employed where it is most effective, but in a somewhat limited way as compared with previous years.

Lime-sulphur-salt wash is gaining in popularity. The author recommends a formula containing 50 lbs. each of lime, sulphur, and salt per 150 gal. of water. Some success has been had in the preparation of this mixture without boiling. In such cases some form of caustic potash or soda is used. Calcothion was used with quite satisfactory results, but the effects were somewhat irregular. A detailed account is given of insecticide operations in the author's experiment orchard.

The economic relation of birds to agriculture is discussed at some length, and attention is called to the fact that the beneficial effects of birds in the destruction of injurious insects have been frequently overestimated. In discussing the robin, the author states that "there is not a single species [of insect] of economic importance eaten by the bird which can not be easily kept in check by the horticulturist." A report is also made on a mosquito investigation in New Jersey. The migrating habit of *Culex sollicitans* has been fully demonstrated.

Further breeding experiments are being carried on to determine some of the doubtful points in the life history of mosquitoes. Estimates made by reliable engineers indicate that a thorough and satisfactory scheme of drainage can be put in operation in mosquito-ridden localities for comparatively small outlays.

Department of entomology, E. D. BALL (*Utah Sta. Rpt. 1903, pp. XXVIII–XXXII*).—Notes are given on the progress of the author's work in combating codling moth, especially a commercial test of spraying for this insect which has been undertaken but is not yet complete. In these experiments Paris green is used without the addition of lime.

An investigation was also made of the grasshopper situation, particularly in San Pete and Sevier counties, where it was found that large numbers of grasshoppers had been caught by means of the "ballooning" method for bounty. At the town of Chester 46,429 lbs. of grasshoppers were received for bounty. An estimate of the number of grasshoppers in the masses which were received was made with the result that a ton of grasshoppers is believed to contain 32,000,000 individuals. Brief notes are also given on tent caterpillars.

About some injurious insects, S. ONUKI and H. NAKAGAWA (*Imp. Agr. Expt. Sta. Japan, Bul. 30, pp. 152, pls. 14*).—This bulletin is accompanied with an English abstract of 11 pages in which the main points are summarized. The authors present biological and economic notes on a considerable number of miscellaneous insects injurious to rice, pear, mulberry, and tea. Experiments were also carried on with insecticides.

It was found that *Lema flaviceps*, a leaf-eating beetle injurious to rice, could be destroyed in the larval condition by dusting with a mixture of 1 part pyrethrum to 4 parts lime. The adult insects, however, were not affected by this treatment. Good results were also obtained in controlling this insect by the use of Paris green and kerosene. Various insecticides were tested on a species of sawfly, which is injurious to the common rush used in making mats. Pyrethrum and lime proved effective in destroying this species. It was also found that the larvæ could be destroyed by burying them in mud at a depth of 5 to 8 in.

The woolly aphis was effectively exterminated by a treatment during winter with kerosene of the strength of 5 per cent. In the experiments of the authors the pear-tree psylla was most easily destroyed by a mixture of kerosene and water at the rate of 1 to 15.

Reports on economic zoology, F. V. THEOBALD (*Jour. Southeast. Agr. Col., Wye, 1904, No. 13, pp. 113–185, pls. 10, figs. 16*).—An account is given of the life history and habits of various ticks with especial reference to their agency in spreading malignant jaundice in dogs, heart water in sheep, Texas fever in cattle, and louping ill in sheep.

An elaborate discussion is also given of the insect pests of the raspberry with notes on their habits and life history and the means of preventing them. Attention is also called to certain birds which feed upon this fruit. The author discusses briefly some of the results thus far obtained from the use of lime-sulphur-salt wash and recommends a formula containing 40 lbs. lime, 20 lbs. sulphur, and 15 lbs. salt per 50 gal. of the wash. The animal pests of forest trees are discussed in considerable detail with especial reference to the insects injurious to ash, alder, aspen, beech, birch, and horse-chestnut.

The beetles of Central Europe, L. GANGLBAUER (*Die Käfer von Mitteleuropa. Vienna: Karl Gerolds Son, 4 (1904), pt. 1, pp. 286, figs. 12*).—The author continues his monograph on the beetles of Central Europe giving analytical keys for the determination of species and detailed descriptions of species, with brief notes on their occurrence and habits. The families considered in this part of the author's work are Dermestidæ, Byrrhidæ, Nosodendridæ, Georyssidæ, Dryopidæ, Heteroceridæ, and Hydrophilidæ.

Beetle pests (*Pul. Dept. Agr. Jamaica, 2 (1904), No. 10, pp. 217, 218*).—Notes are given on injuries to rose trees and other plants caused by the attacks of *Antichira meridionalis* and also on the depredations of *Oncideres pustulata* on beech.

Bactericidal properties of the body fluids of worms, L. JAMMES and H. MANDOUL (*Compt. Rend. Acad. Sci. Paris, 139 (1904), No. 4, pp. 329–331*).—In a study of various species of Ascaris it was found that the fluids produced by these worms had no effect upon pathogenic bacteria. The lesions produced by such bacteria were formed as quickly and in as great extent after the bacteria had been subjected to the action of the juices of Ascaris as before. The fluids produced by species of Tænia, however, appear to contain a soluble bactericidal substance capable of influencing the growth and virulence of pathogenic bacteria to a considerable extent.

Notes on entomology, N. BANKS (*Science, n. ser., 20 (1904), No. 500, pp. 155, 156*).—Brief notes on recent entomological literature.

Observations made on plantations in east and west Usambara, A. ZIMMERMANN (*Ber. Land- u. Forstw. Deutsch-Ostafrika, 1 (1903), No. 4, pp. 351–381, pl. 1, figs. 2*).—The author describes briefly the general conditions of plantations, especially those devoted to coffee, with reference to the most important insect pests and fungus diseases. Among the latter, especial mention is made of *Hemileia vastatrix*.

A considerable number of injurious insects were observed attacking coffee, the most important of which was the leaf miner *Cemiostoma coffeellum*. This insect is described in its different stages, and an outline was presented of its life history and its attacks upon coffee. Brief notes are also given on other insects and nematode worms injurious to coffee.

Cheimatobia brumata and means of combating it, G. LIND (*K. Landt. Akad. Handl. och Tidskr., 43 (1904), No. 3, pp. 253–272, figs. 8*).—This insect causes considerable damage to fruit trees almost every year. Notes are given on its habits and life history and on the best means for combating it. It is recommended that fruit trees be sprayed with Paris green at the rate of 50 gm. per 100 liters of water to which 150 gm. slaked lime are added. This mixture should be applied to the trees when the leaf buds are first opening, again when the petals are falling, and a third time about 10 days later. Sticky bands and other obstacles placed on the trunk of the tree may serve to prevent the females from laying their eggs.

Notes on the migratory locust (Acridium peregrinum), W. CARTWRIGHT (*Jour. Khediv. Agr. Soc. and School Agr., 6 (1904), No. 3, pp. 81–89*).—The life history of this insect in its various stages is briefly discussed. According to the author's observations the period of incubation of eggs appeared to be about 21 days. It was found that simple exposure of eggs to the sun for a period of one hour at a temperature of 88° F. was sufficient to kill them. This may be readily brought about by a thorough plowing. The young nymphs may be successfully combated by the use of a system of trenches and sticky obstacles. Brief notes are also given on birds which feed upon this pest.

Lantana insects (*Queensland Agr. Jour., 15 (1904), No. 3, pp. 655–657*).—Lantana has spread rapidly in many districts of Queensland and has proved a very noxious weed.

In Mexico a number of insects are known to attack the plant to such an extent as to greatly prevent its spread. Some of these insects have been introduced into Hawaii where lantana is also a serious pest. Ten species were introduced but failed to establish themselves. They died either during shipment or subsequently as a result of insect parasites or fungus diseases. Brief notes are given on the results of the importation of other species which withstood the hardships of transportation. These insects appear to be able to check lantana to some extent but not to destroy it.

The aleurodids or mealy-winged flies of California with reference to other American species, FLORENCE E. BEMIS (*Proc. U. S. Nat. Mus., 27 (1904), pp. 471–537, pls. 11*).—This family of insects is found rather plentifully represented in parts

of California, and many of them are of considerable economic importance. A general account is given of the external anatomy, life history, and habits of this group, together with analytical keys and detailed descriptions of the species.

The Mexican cotton-boll weevil, W. NEWELL (*Georgia State Bd. Ent. Bul. 12, pp. 29, figs. 21*).—The cotton-boll weevil is described in its various stages, and notes are given on various other phases of the weevil problem, such as the rate of increase and destructiveness of the pest, artificial remedies, the relation of birds to the boll weevil, insects frequently mistaken for this pest, and the quarantine law of Georgia regarding the boll weevil.

The cabbage worm, M. L. MERRITT (*Iowa Agr., 5 (1904), No. 3, pp. 86, 87*).—Notes are given on the habits and life history of *Pieris rapæ*. In combating this insect a dust spray of Paris green at the rate of 1 part to 25 parts air-slaked lime is recommended. A satisfactory liquid insecticide may be prepared so as to contain 5 lbs. pulverized resin, 1 lb. concentrated lye, 1 pt. fish oil, and 5 gal. water. This stock material after boiling for 2 hours is to be diluted at the rate of 1 gal. per 16 gal. of water.

The discovery of the native home of the San José scale in Eastern China and the importation of its natural enemy, C. L. MARLATT (*Pop. Sci. Mo., 65 (1904), No. 4, pp. 306–317, figs. 8*).—A popular account is given of the author's travels in China and Japan, together with notes on the agency of *Chilocorus similis* in controlling the San José scale.

The morphology, classification, and systematic position of Anoplura with notes on insect orders, G. ENDERLEIN (*Zool. Anz., 28 (1904), No. 4, pp. 121–147, figs. 15*).—Notes are given on the anatomy of the various parts of the body of Anoplura with especial reference to the importance of these characters in the scientific system of classification. An analytical table is given to assist in the identification of various families and genera of lice, a number of which are described as new.

The bearing of these studies upon the general classification of the orders of insects is indicated. In this connection attention is called to the great confusion which has resulted from the continual introduction of new names for insect orders.

List of the Tabanidæ (horseflies) of North Carolina, C. S. BRIMLEY and F. SHERMAN, Jr. (*Ent. News, 15 (1904), No. 8, pp. 270–275*).—A list of horseflies reported in this paper is based on collections made by the authors during the past 2 years and covers species captured at various altitudes from sea level to 4,000 ft.

The habits of adult mosquitoes of the genus Anopheles in relation to hydraulic engineering, E. PERRONE (*Atti Soc. Studi Malaria, 5 (1904), pp. 49–64*).—The breeding habits of mosquitoes are briefly noted, with especial reference to artificial waterways as breeding places for mosquitoes and as means of draining such breeding places. The beneficial effects of draining have been noted in a number of localities.

An acarid parasite of Anopheles, H. GROS (*Compt. Rend. Soc. Biol. [Paris], 56 (1904), No. 2, pp. 56, 57*).—Specimens of *Anopheles maculipennis* were captured with a small parasite attached to the body. The parasite possesses a round, ill-defined form of a reddish or violet color. Notes are given on the structure of the organism, which may prove to be a true parasite, or is, perhaps, more correctly considered a commensal organism.

Acarid parasites of Anopheles, EDMOND and ÉTIENNE SERGENT (*Compt. Rend. Soc. Biol. [Paris], 56 (1904), No. 3, pp. 100–102*).—It was found that the acarid parasites observed attached to the bodies of *Anopheles algeriensis* may become transferred to *A. maculipennis* if the 2 species are kept confined in the same cage.

A new species of tsetse fly (Glossina decorsei) from Central Africa, E. BRUMPT (*Compt. Rend. Soc. Biol. [Paris], 56 (1904), No. 13, pp. 628–630*).—This species is described as new and brief notes are given on its habits and life history. The bite of

the fly is said to be painful and produces a pruritis which exists for some time. The insect lives like related species on blood and is believed to be equally pathogenic with *G. morsitans*, *G. pallidipes*, and other related species.

A revision of American siphonaptera or fleas together with a complete list and bibliography of the group, C. F. BAKER (*Proc. U. S. Nat. Mus., 27 (1904), pp. 365–469, pls. 27*).—The present monograph is the result of about 14 years' work on this group, during which time the author has received assistance from various entomologists. The characteristic features of the anatomy of fleas are briefly noted and the basis of classification is explained. Analytical keys are given for the determination of species, and an extensive bibliography of papers dealing with this subject is presented.

Display of bees at the World's Fair, F. N. BERTHE (*Iowa Agr., 5 (1904), No. 3, pp. 79, 80*).—Brief notes on the nature and purpose of the exhibits in apiculture at the World's Fair at St. Louis.

The bee and the orchard (*Queensland Agr. Jour., 15 (1904), No. 3, pp. 639, 640*).—A brief discussion is presented of the agency of bees in pollinating orchard trees. The question whether bees injure sound fruit is also considered with particular reference to the orange. Apparently oranges are not attacked by bees until the skin has first been perforated by some other insect.

A preliminary investigation into the cause of the infectious bee disease prevailing in the State of New York, V. A. MOORE and G. F. WHITE (*Rpt. New York State Dept. Agr., 10 (1902), pp. 255–260, pls. 2*).—The infectious bee diseases in New York are referred to under the names "black brood," "foul brood," and "pickle brood."

An investigation of a number of cases of "black brood" showed that *Bacillus alvei* was present in every instance, while in outbreaks of "pickle brood" and "foul brood" this organism was not found and no micro-organisms were definitely identified. The authors are inclined to believe that there is but one infectious disease, namely, "foul brood," which appears under the three forms.

Silk culture, C. W. WOODWORTH (*California Sta. Circ. 12, pp. 6*).—Silkworms have been raised for many years in California, but not with profit except for a brief period, when there was a European market for silkworm eggs from California. The present circular is issued for the information of correspondents who are interested in silk raising. The station is making experiments for the purpose of determining whether it is possible to reduce the cost of producing raw silk in California. Little hope is expressed, however, of much success in this line.

Cocoons that yield colored silk, J. C. COVERT (*U. S. Dept. Com. and Labor, Mo. Consular Rpts., 1904, No. 287, pp. 36–38*).—An account is given of the experiments conducted by Comte and Levrat in Lyon, France, in attempting to influence the color of silk by feeding silkworms colored food. It appears that the main purpose of these experiments was not to gain any great commercial advantage in the natural coloring of silk, but to determine why some breeds of silkworms produce white silk while others yield a yellow or yellowish-green silk.

According to the experiments it seemed that the coloring matter of the cocoons was identical with that found in the leaves, and further experiments showed that the coloring matter introduced into the intestines of silkworms may have an influence upon the color of the silk produced. Silkworms were fed on leaves dipped into different colored liquids, and it was found possible to produce in this manner silk of a beautiful red color. Further experiments along this line will be carried out.

The natural coloration of silk, A. CONTE (*Compt. Rend. Soc. Biol. [Paris], 57 (1904), No. 25, pp. 54, 55*).—This is a controversial article in which the author combats the opinion of J. Villard, who maintained that the green coloration of the silk of *Antherea yamamai* and of *Rhodia fugax* was not due to chlorophyll.

The natural coloration of silk, R. Dubois (*Compt. Rend. Soc. Biol.* [*Paris*], *57* (*1904*), *No. 27*, *pp. 201–203*).—A controversial article in which the author replies to the contentions of A. Conte.

Silk industry in Japan in 1903 (*U. S. Dept. Com. and Labor, Mo. Consular Rpts., 1904, No. 287, pp. 13–15*).—Statistics are given showing the total trade of Japan in silk in 1902–3, the growth of the export of raw silk in Japan, and other matters relating to the silk industry.

FOODS—NUTRITION.

Food inspection and analysis, A. E. Leach (*New York: John Wiley & Sons; London: Chapman & Hall, Ltd., 1904, pp. XIV+787, pls. 40, figs. 120*).—In preparing this comprehensive work the author has had in mind the requirements of public analysts, as well as other officials who are intrusted with carrying out the provisions of State and municipal laws dealing with the suppression of food adulteration, and naturally special prominence is given to the nature and extent of the adulteration of various foods, methods for the analysis, the detection of adulterants, and to the details of food inspection.

Considerable space is also given to the general composition of foods, and analytical processes, which are suited to the needs of the sanitary chemist and others who might wish to determine the proximate composition of food materials, are considered. The processes of manufacture of cereal breakfast foods, infant foods, and other classes of food materials, especially those likely to contain impurities, are briefly described. Considerable attention is paid to the use of the microscope in connection with the examination of foods and condiments, a feature of the volume being the reproduction of a large number of photomicrographs made in the author's laboratory, illustrating powdered pure foods and food products and powdered adulterants, types of adulterated foods chosen from samples collected in the course of inspection work, and permanently mounted sections of foods and adulterants.

The volume contains numerous references to the work of other investigators and similiar bibliographical data, as well as a complete index, and is also provided with standard tables and similar data.

Report of the inspector of foods for export, A. A. Brown (*Jour. Dept. Agr. Victoria, 2* (*1904*), *No. 9, pp. 889–895*).—Statistical and other data are reported and discussed.

Report of the dairy and food commissioner, B. H. Warren (*Pennsylvania Dept. Agr. Rpt. 1903, pp. 64–70*).—Information is given regarding the amounts received from fines and other data having to do with the State pure-food law and its operation.

Bread and meat, Y. Guyot (*Le pain et la viande dans le monde. Paris: Guillaumin & Co., 1904, pp. 49*).—In this article, which is reprinted from *Revue du Commerce, de l'Industrie et de la Banque*, the author discusses the available supply of meat and cereal grain, and its adequacy if the proper amount were generally consumed, the whole question being considered from the standpoint of economics. According to the author the available grain and meat supply of the world is insufficient, and better economic conditions are needed. The article contains some references to early food investigations.

The nitrogenous constituents of flesh, H. S. Grindley (*Jour. Amer. Chem. Soc., 26* (*1904*), *No. 9, pp. 1086–1107*).—Extended studies of the nitrogenous constituents of meat are reported. The general conclusions drawn were in effect as follows:

A considerable proportion of raw flesh food is soluble in cold water, the data showing that 12.14 per cent of the total proteid of raw flesh and 22 per cent of the total nitrogen was thus soluble. "The nitrogen existing in cold water extracts of raw meat is equally divided between proteid and nonproteid substances. The acid-

ity of a solution of flesh increases upon the coagulation of its proteids. The proteids of cooked meat are much less soluble than those of raw flesh in cold water and 10 per cent sodium chlorid solution.

"Cold water extracted 3.06 per cent of nitrogenous matter from raw meats and only 0.27 per cent from boiled meat. A 10 per cent solution of sodium chlorid extracted from raw meats 6.10 per cent of proteid matter and only 0.5 per cent from boiled meat. A 0.15 per cent solution of hydrochloric acid dissolved from raw meat 2.28 per cent of proteid and from boiled meat 2.30 per cent. A 0.15 per cent solution of potassium hydroxid extracted from raw meats 2.88 per cent and from boiled meat 4.84 per cent of proteid.

"Hot water removed from raw meats 0.49 per cent and from boiled meats 6.24 per cent proteid matter. Of the total proteid existing in the original raw meats 95.22 per cent was dissolved by extracting successively with the following reagents: Cold water, 10 per cent sodium chlorid solution, 0.15 per cent hydrochloric-acid solution, 0.15 per cent potassium-hydroxid solution, and hot water, while only 50.59 per cent of the total proteid of the boiled meat was thus made soluble."

The results of this investigation were embodied in a paper presented by the author at the meeting of the American Association for the Advancement of Science at St. Louis, December, 1903. (See Science, n. ser., 19 (1904), No. 481, p. 444.)

Arsenic in food stuffs, W. Thomson (*British Food Jour., 6 (1904), Nos. 66, pp. 126–129; 67, pp. 152, 153; 68, pp. 171, 172, figs. 9*).—In a paper read before the Philosophical Society of Manchester, December, 1903, the author describes experiments on the detection and estimation of arsenic by electrolytic methods as compared with results obtained by the Marsh-Berzelius process.

Arsenic in food products, V. Bordas (*Compt. Rend. Acad. Sci. Paris, 139 (1904), No. 3, pp. 234–236*).—Examinations for the detection of arsenic are reported of chicory, malt, glycerol, and other products, the amounts found in some cases being sufficient to cause alarm, according to the author, if the materials are used by infants.

Alimentary origin of arsenic in man, A. Gautier and P. Clausmann (*Compt. Rend. Acad. Sci. Paris, 139 (1904), No. 2, pp. 101–108; Compt. Rend. Soc. Biol. [Paris], 57 (1904), No. 25, pp. 55–58*).—Believing that the arsenic in animal tissues is indispensable and not accidental, 41 samples of animal and vegetable foods, beverages, etc., were analyzed, arsenic being found in all with the exception of beans and cabbages. It was especially abundant in the flesh of fish and crustacea. The author calculates that the daily diet would furnish 0.021 mg., or in a year 7.66 mg., an amount which is regarded as sufficient for the needs of the body.

Changes in asparagus when kept in water, K. Windisch and P. Schmidt (*Ztschr. Untersuch. Nahr. u. Genussmtl., 8 (1904), No. 6, pp. 352–355*).—Investigations showed that when asparagus is stored in water to keep it fresh it loses in flavor and nutritive material.

Note on mushroom catsup, J. F. Liverseege (*Analyst, 29 (1904), No. 340, pp. 208, 209*).—Analyses of mushroom catsup are reported, and the article is followed by a discussion of the manufacture of this product.

A further note on mushroom catsup, J. F. Liverseege (*Analyst, 29 (1904), No. 342, p. 283*).—Analytical data are reported. It is stated that the so-called mushroom catsup is now made from pig liver without the use of any mushrooms.

Composition and adulteration of ground mustard, A. E. Leach (*Jour. Amer. Chem. Soc., 26 (1904), No. 10, pp. 1203–1210, fig. 1*).—Analytical studies are reported of mustard and mustard hulls; mustard adulterants are spoken of, and standards of purity suggested. The author notes that pure mustard contains no starch, yet mustard hulls of all varieties show by the diastase method considerable material which reduces copper but which is not starch. The importance of a microscope in examining mustard is pointed out.

Ground mustard (water and fat-free material) should contain, according to the

author, not more than 2.5 per cent reducing material (expressed as dextrose) when treated with diastase, not more than 5 per cent crude fiber, and not less than 8 per cent total nitrogen. As shown by the microscope, it should be free from more than minute traces of starch and should not exhibit an excess of hulls over seed tissue.

The composition of chocolate varnish, F. JEAN (*Ann. Chim. Analyt., 9 (1904), No. 7, p. 258*).—A preparation used in Spain for hardening chocolate and preventing its becoming white on keeping contained 25.6 gm. gum benzoin and 6.4 gm. of an unidentified resin in 100 cc. of alcohol.

Candied honey in paper packages (*Jour. Agr. and Ind. South Australia, 7 (1904), No. 12, pp. 679–681, figs. 4*).—Statistics are given regarding the production of honey in South Australia, and directions quoted for preparing candied honey in convenient form for marketing in paper packages, the data on the latter topic being summarized from articles which have appeared in *Gleanings in Bee Culture.*

Under favorable conditions extracted honey will granulate and become solid, so that it may be conveniently handled. If honey is stirred or agitated the granulation is hastened. The smaller the movement and slower the motion the better the results. The best results are obtained on a warm dry day. The packages should be arranged and the honey poured into them while warm. It is stated that the honey if properly treated quickly becomes solid when poured into the packages and can then be handled readily.

Roasted beet root, E. G. CLAYTON (*Analyst, 29 (1904), No. 342, pp. 279, 280*).—Analyses are reported of roasted beet root, which is used as a substitute for or addition to chicory. Judged by the values obtained, it contains a larger proportion of total mineral matter and soluble ash than is usually present in torrefied chicory, and yields more soluble ash. When treated with boiling water the percentage of sugar is also decidedly higher.

Concerning the oil from the seeds of Carthamus tinctorius, G. FENDLER (*Chem. Ztg., 28 (1904), No. 74, pp. 867, 868*).—Analytical data are reported. On account of its disagreeable taste the author believes that this oil is not satisfactory for culinary purposes, but that it might be used for the manufacture of soap and possibly for varnish, etc.

The formation of free acid in olive oil and the rancidity of this oil, R. MARCILLE (*Seifensiederzeitung, 31, pp. 630, 631, 656, 657, 671, 672, 691, 692; abs. in Chem. Centbl., 75 (1904), II, No. 15, p. 1064*).—This article has to do with the souring and rancidity of olive oil, which, according to the author, have distinct causes, the souring being principally due to the action of micro-organisms, especially molds, and the rancidity being due to the absorption of oxygen from the air. Suggestions for avoiding such changes are given with special reference to the olive industry.

Canned goods with special arrangements for heating, P. BUTTENBERG (*Ztschr. Untersuch. Nahr. u. Genussmtl., 8 (1904), No. 6, pp. 355–357, figs. 2*).—The canned goods described are provided with special arrangements for heating the contents without making a fire. In one case the heat is derived from so-called hard spirit contained in a receptacle attached to the can, and in the other by allowing water containing a little acetic acid to act upon unslaked lime, these ingredients being also contained in receptacles attached to the can. The goods described are designed for use where it is not practicable to heat foods over fire.

Canning pineapples, H. N. RIDLEY (*Queensland Agr. Jour., 15 (1904), No. 2, p. 554*).—In an article quoted from the *Agricultural Bulletin of the Straits and Federated Malay States* the local methods of canning and preserving pineapples are described.

Progress report on the use of native sugars for preserves, H. H. COUSINS (*Bul. Dept. Agr. Jamaica, 2 (1904), No. 8, pp. 172, 173*).—Some analytical data regarding native sugars are given, and experiments are reported on their use with and without preservatives in the manufacture of jams, etc. "Our best native sugars are of high quality, but are all infected with the fermentive Torula and special treatment

is required to ensure a sterile preserve. Sulphur dioxid and calcium bisulphite appear to be the best chemical preservatives for fruit pulp, fruits in sirups, and jams made with native sugars."

The cooperative bacon-curing industry of Denmark, VISCOUNT IKERRIN, P. J. HANNON, L. J. D'ALTON, and J. J. SLATTERY (*Dept. Agr. and Tech. Instr. Ireland, Bul. 5, pp. 43, fig. 1*).—The handling, curing, and marketing of bacon by cooperative societies in Denmark is described. The industry, as thus managed, has assumed large proportions and the cooperative societies seem to be very satisfactory in their operation.

The composition of duck egg with reference to its use in the manufacture of egg noodles and similar goods, H. LÜHRIG (*Ztschr. Untersuch. Nahr. u. Genussmtl., 8 (1904), No. 3, pp. 181–188*).—According to the author's analyses, a duck egg on an average contains 24 gm. of yolk with 13.17 gm. dry matter, 8.13 gm. fat, and 0.205 gm. lecithin-phosphoric acid, and 36 gm. white with 4.57 gm. dry matter and 0.02 gm. fat. Numerous analyses are reported and discussed with special reference to the use of duck eggs in egg noodles and similar egg pastes, and the lecithin content of alimentary pastes as an indication of the quantity of egg used in their manufacture.

Judging egg noodles and similar goods, H. LÜHRIG (*Ztschr. Untersuch. Nahr. u. Genussmtl., 8 (1904), No. 6, pp. 337–347*).—Data regarding the analysis of noodles and similar goods containing eggs are reported and discussed with special reference to a similar article by H. Jaeckle recently noted (E. S. R., 16, p. 284).

Note on the chemical examination of the fruits [of ficus], O. REINHERZ (*Agr. Ledger, 1904, No. 4 (Veg. Prod. Ser., No. 80), pp. 25–32*).—Data are given regarding the composition of the fruit of the banyan tree and other sorts of ficus found in India, the use of these fruits as food, distribution of the species referred to, and related topics, as well as brief notes on the character of the coloring matter of ficus fruits.

Preserved buttermilk, a new infant food, P. SELTER (*Deut. Med. Wchnschr., 29 (1903), pp. 486, 487; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 8 (1904), No. 6, p. 375*).—On the basis of his experience and observation, the author regards preserved buttermilk as a useful food for both ill and healthy children.

Feeding infants with whole milk curdled with rennet, THERESE OPPLER (*Inaug. Diss., Univ. Breslau, 1903; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 8 (1904), No. 6, pp. 374, 375*).—Though a number of infants were nourished for several weeks or months without harm on whole milk curdled with rennet, equally satisfactory results were not obtained in all cases, and definite conclusions regarding the value of this preparation were not drawn.

Investigations on the nutrition of man, W. O. ATWATER (*Nature [London], 70 (1904), No. 1825, pp. 617, 618*).—A summary of an address before the sections of physiology and economics at the Cambridge meeting of the British Association on August 23, 1904, in which the author described briefly the nutrition investigations which have been carried on under the auspices of the Office of Experiment Stations, pointed out some of the more important results obtained and their possible application, and spoke of the importance of extending the work along a number of lines.

Filipino ration, J. F. WESTON (*Com. Gen. Subsist. [U. S. Army] Rpt. 1904, p. 29*).—The data reported show the components of the Filipino ration prescribed by the War Department.

Food and diet, S. BELOTTI (*Bromatologia. Milan: Ulrico Hoepli, 1904, pp. 251, pls. 12; rev. in Hyg. Rundschau, 14 (1904), No. 20, pp. 1001, 1002*).—The laws of nutrition and the nutritive value of the principal classes of foods are discussed in this volume, particularly the foods which are of most importance to the Italian people. Some statistics are given regarding olive products in Italy and a summary of data regarding the composition of country and town milk.

Diet tables of Italian hospitals, A. FRASSI (*Riv. Ig. e San. Pubb., Roma, 15 (1904); abs. in Hyg. Rundschau, 14 (1904), No. 20, pp. 999-1001*).—Diet tables of 55 hospitals are given and the nutritive value of the rations for different classes of patients calculated. The data presented are discussed in relation to the general question of diet.

The Japanese soldier's outfit, with notes on the rations (*British Med. Jour., 1904, No. 2289, pp. 1327, 1328, figs. 10*).—A brief description of the equipment of the Japanese soldiers. Attention is especially called to the ready boiled rice which is supplied, and the biscuits made of wheat and rice flour with a few grains of millet seed to prevent them from becoming too hard. Dried vegetables of various kinds, including sliced potatoes, carrots, beans, sliced gourd, etc., are issued, as well as tea and salt in solid cakes or cubes, and various meats and fish in tin. To diminish weight and simplify transportation problems the fodder for the horses is specially prepared by drying.

Cost of living and retail prices in the United States, G. W. W. HANGER (*U. S. Dept. Com. and Labor, Bureau of Labor Bul. 54, pp. 1129-1164, charts 21*).—A number of the charts showing the cost of living and retail prices in the United States, prepared for the exhibit of the Bureau of Labor at the Louisiana Purchase Exposition, are reproduced, and the material presented is described. The records are based on data secured in 25,440 families residing in the principal industrial localities in 33 States. (See also E. S. R., 15, p. 493).

The regulation of dietaries in hospitals and other public institutions, W. ALBRAND (*Die Kostordnung an Heil- und Pflege-Anstalten. Leipzig: H. Hartnung & Son, 1903, pp. 79; rev. in British Med. Jour., 1904, No. 2284, p. 925*).—Dietetics of institutions are discussed and dietaries proposed, particularly for patients, nurses, and officers of hospitals for the insane.

The influence of sodium chlorid on stomach digestion, BÖNNIGER (*München. Med. Wchnschr., 1904, No. 2; abs. in Zentbl. Physiol., 18 (1904), No. 8, p. 262*).—In experiments with a dog with a Pawlow fistula, sodium chlorid solution introduced into the main stomach diminished the flow of gastric juice to about 25 per cent of the quantity found in a control animal given no salt. The effect was attributed to reflex nervous action.

Human pancreatic juice, HAMBURGER and HEKMA (*Jour. Physiol. et Path. Gén., 1904, Jan., p. 40; abs. in Rev. Soc. Sci. Hyg. Aliment., 1 (1904), No. 1, p. 93*).—According to the authors, human intestinal juice contains enterokinase, amylase, sucrase, and erepsin. It is without action on lactose and cellulose, but attacks casein directly.

The fat-cleaving ferment of the intestinal juice, W. BOLDIREFF (*Zentbl. Physiol., 18 (1904), No. 15, pp. 460, 461*).—The fat-cleaving properties of the intestinal juice were not hindered by antiseptics, like calomel or thymol, while filtering the juice diminished though it did not destroy these properties. The ferment action of the intestinal juice, the author concludes, is due to a specific ferment and is not rendered active by the gall.

The effect of alcohol, sugar, and tea upon the ability of muscles to produce work, A. F. HELLSTEN (*Skand. Arch. Physiol., 16 (1904), No. 3-4, pp. 139-221, dgm. 1*).—Ergographic experiments made with a man showed that, almost immediately after taking, alcohol increased the muscular power, but after 10 to 40 minutes the power began to diminish and this effect lasted 2 hours. The reaction followed with large doses of alcohol somewhat more quickly than with small doses.

Sugar increased the muscular power, the effect being noticed about 40 minutes after the solution was taken. The favorable effect of sugar was especially noticeable when the amount of work per unit of time was considered. The effect of tea on muscular work was but slight and lasted for only a short time. The effect was noticeable almost as soon as the tea infusion was taken.

The excretion of carbon dioxid when different sorts of sugar are consumed, J. E. JOHANSSON, J. BILLSTRÖM, and C. HEIJL (*Skand. Arch. Physiol., 16 (1904), No. 3-4, pp. 263-272, figs. 5*).—Respiration experiments with men were made to determine the effect of different sorts of sugar upon the excretion of carbon dioxid. Cane sugar and levulose were found to have much the same effect. With levulose the increase was much greater than with dextrose, which would go to show that the levulose is burned more quickly in the body and stored in the form of glycogen less rapidly than dextrose.

Muscular contraction and energy, A. CHAUVEAU (*Compt. Rend. Acad. Sci. Paris, 138 (1904), No. 24, pp. 1465-1470; abs. in Jour. Chem. Soc. [London], 86 (1904), No. 502, II, pp. 575, 576*).—Using a new form of apparatus, the conditions of muscular work in man can, in the author's opinion, be accurately studied. The amount of oxygen absorbed during work is very nearly proportional to the work done. When working slowly the values of the oxygen absorbed are reduced. The respiratory quotient is always increased. Both static and dynamic forms of muscular contraction were studied. In the former the muscles of the forearm worked against measured resistance without raising a weight, while in the second a weight was raised.

Observations on hygiene, A. PROUST, A. NETTER, and H. BOURGES (*Traité d'hygiène. Paris: Masson & Co., pp. 1245, figs. 204; rev. in Rev. Soc. Sci. Hyg. Aliment., 1 (1904), No. 1, p. 95*).—One of the principal sections of this handbook is devoted to food and diet.

ANIMAL PRODUCTION.

Fodders and feeds, L. A. VOORHEES ET AL. (*New Jersey Stas. Rpt. 1903, pp. 76-122*).—Data are given regarding the analysis of commercial feeding stuffs and their market prices. The analytical data have been noted from a previous publication (E. S. R., 15, p. 288).

Changes in the composition of corn meal due to the action of molds, J. P. STREET (*New Jersey Stas. Rpt. 1903, pp. 123-147*).—The author has continued his studies of the changes brought about in corn meal by the growth of micro-organisms (E. S. R., 14, p. 380). It was found that the spores of *Penicillium glaucum* and certain bacteria are generally present in commercial corn meal and will develop spontaneously under proper conditions of moisture, from 25.42 to 38.40 per cent being favorable to the growth of mold. The maximum growth was obtained at the lower figure. Not only does an excess of moisture cause an increased growth of mold, but with this increase of mold also appears a large increase of moisture, in one of the experiments reported amounting to 68.5 per cent. The action of *P. glaucum* on the food constituents of the meal is probably due to the enzyms it secretes.

The loss of fat varied from 3.5 to 70.4 per cent, according to the amount of water present, reaching the maximum with a moisture content of 25 to 29 per cent. With a moisture content of 21 per cent there was a development of mold, only visible microscopically, but yet causing a loss of over 12 per cent of fat. The losses in total proteids were small. However, when bacteria were present this loss was very large. Not only were total proteids lost, but the chief part of this loss fell on the albuminoids, a part being converted into less valuable amido-compounds, and other portions being volatilized as ammonia.

The changes in total ash were trifling. The changes in crude fiber were small where *P. glaucum* alone was used, but in the presence of Mucor and the bacterial growth an increase of fiber from 72 to 78 per cent was observed. *P. glaucum* had practically no effect on the total nitrogen-free extract, but Mucor and the bacteria caused very great losses.

Inspection of concentrates, J. B. LINDSEY (*Massachusetts Sta. Bul. 98, pp. 35*).—The standards required by the State feeding stuff law are quoted and analyses reported of a number of samples of blood meal, cotton-seed meal, linseed meal, old and new process; gluten meal and feed, dried distillers' grains, malt sprouts, wheat middlings and bran, mixed feeds, feeds containing molasses, oats and oat middlings, rye feed, corn meal, hominy meal, corn and oat feeds, provender, oat feeds, miscellaneous starchy feeds, and a number of poultry feeds, including meat scraps, meat and bone meal, fish, bone, mashes, and meals, chick and scratching grains, and clover meal. Some data are also given regarding the market value of concentrated feeds.

It is stated that the large majority of manufacturers, jobbers, and retail dealers have fully conformed to the requirements of the feeding-stuff law. It was found that a few dealers offered their goods unbranded and unguaranteed.

Discussing the poultry feeds the author notes that there was "no product on the market which varied more in feeding value [than meat scraps], some samples having nearly twice the value of others. In purchasing preference should be given to fine ground brands of high protein content, small to medium amounts of bone, and relatively low percentage of fat, under 20 per cent rather than over."

When oats are high in price, as was the case, according to the author, during the last 6 months of the year, when the retail price was practically $36 per ton, "feeders naturally look for oat substitutes and are inclined to reduce the oat ration to a minimum and substitute hominy chop, dried brewers' and distillers' grain, and wheat bran."

Report of the chemist, W. FREAR (*Pennsylvania Dept. Agr. Rpt. 1903, pp. 590–604*).—The composition and feeding value of dried brewers' and distillers' grains are discussed and a large amount of data on the subject given. Station analyses of dried distillers' grains are quoted.

Cactus as feed for farm animals, A. JEHANNE (*Jour. Agr. Trop., 4 (1904), No. 33, pp. 72–76*).—Data regarding the feeding value of Indian fig (*Opuntia ficus indica*) are summarized.

The forest as a source of forage for farm animals, L. GRANDEAU (*Jour. Agr. Prat., n. ser., 8 (1904), No. 37, pp. 333, 334*).—A summary of data regarding the use of leaves and branches in the feeding of farm animals.

Pie melons as a fodder crop (*Jour. Agr. and Ind. South Australia, 7 (1904), No. 11, pp. 620, 621, fig. 1*).—A brief note pointing out the value of stock or pie melons as a succulent feed for cattle, pigs, and poultry.

Laws regarding feeding stuffs (*Jour. Soc. Agr. Suisse Romande, 45 (1904), No. 1, pp. 14–18*).—Swiss laws regarding the sale of feeding stuffs are summarized.

Stock raising in the Philippines (*Breeder's Gaz., 45 (1904), No. 22, pp. 1047, 1048*).—On the basis of information gathered from the Bureau of Insular Affairs of the U. S. War Department, it is stated that stock raising must be built up anew in the Philippines. The location of grazing lands and other topics are briefly spoken of. "Cattle raising for the home market should be very profitable, judging from the prevailing high prices of meat in Manila and the fact that practically all the meat consumed is shipped in on the hoof from Singapore or as refrigerated meat from Australia and the United States."

Calcium phosphate as a part of a ration, V. SCHENKE (*Landw. Vers. Stat., 58 (1903), No. 3–4, pp. 291–312*).—A summary of feeding tests and other data regarding the value of calcium phosphate. The general conclusion is drawn that precipitated calcium phosphate is the most satisfactory form for adding this material to a ration for farm animals. The article includes a bibliography of the subject.

Does an excess of calcium carbonate in feed exercise an effect upon digestibility? J. VOLHARD (*Landw. Vers. Stat., 61 (1904), No. 1–4, pp. 305–312*).—From experiments with sheep fed 50 gm. calcium carbonate daily in addition to a basal ration of

hay and cotton-seed meal with a little salt, the author concluded that the material under consideration did not materially affect the digestibility of the ration.

Notes on the absorption of fat, U. Lombroso (*Compt. Rend. Soc. Biol. [Paris], 71, pp. 396–401; abs. in Zentbl. Physiol., 18 (1904), No. 13, p. 382*).—The experiments reported were made with dogs and have to do principally with the function of the pancreas in the digestion of fat.

Formation of fat from carbohydrates, M. Fischer (*Fühling's Landw. Ztg., 53 (1904), Nos. 10, pp. 368–372; 11, pp. 412–417; 12, pp. 448–455, figs. 4*).—Data regarding the formation of fat from carbohydrates are summarized and discussed, a chemical explanation of such fat formation being one of the topics taken up. The author concludes that the formation of fat from carbohydrates necessitates the presence of a certain quantity of protein and that the protein of a ration must be increased when the carbohydrates are increased in fattening providing the amount of protein is not already sufficient. In the formation of fat from carbohydrates he believes that radicals from the cleavage of protein exercise a reducing effect upon the carbohydrates. The tissue protoplasm takes part in the reaction, an abundance of the latter being necessary for the formation of fat. He calculates that 4 or 5 parts of carbohydrates to one part of protein, in excess of the amounts needed for the physiological functions of the body, are required. Some 40 to 50 per cent of these 2 nutrients is converted into fat. The most economical proportion of protein to nitrogen-free nutrients is spoken of, and the author points out that so many factors must be considered that it is not possible to fix upon a general nutritive ratio which shall always fit a given case.

Cooperative slaughterhouses in Denmark, A. H. Hollmann (*Fühling's Landw. Ztg., 53 (1904), Nos. 11, pp. 393–398; 12, pp. 440–448*).—A descriptive article.

The autodigestion of pepsin, A. Herlitzka (*Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat., 5. ser., 13 (1904), II, pp. 51–57; abs. in Chem. Centbl., 75 (1904), II, No. 10, pp. 784, 785*).—From experiments which are reported, the author concluded that pepsin undergoes autodigestion and is therefore to be considered as a true proteid. The coefficient of digestibility varied directly with the time of digestion.

The anaerobic gaseous exchange of animal organs and the isolation from animal tissues of an enzym causing fermentation, I, J. Stoklasa (*Ztschr. Landw. Versuchsw. Oesterr., 7 (1904), No. 6, pp. 453–483, figs. 2*).—Experiments are reported and discussed.

Dried molasses-beet-pulp, J. B. Lindsey (*Massachusetts Sta. Bul. 99, pp. 1–10*).—The method of manufacturing molasses-beet-pulp is described and analyses and the results of a digestion experiment with sheep reported. It was found that on an average of 3 trials the coefficients of digestibility were as follows: Dry matter 85, protein 64, crude fiber 84, and nitrogen-free extract 91 per cent.

In a feeding test covering 12 weeks with milch cows molasses-beet-pulp and corn meal were compared, the average milk yield per cow on the former ration being 27.7 lbs. and on the latter 29.1 lbs. On the molasses ration the total solids were 155.9 lbs. and the total milk fat 54.1 lbs., and on the corn-meal ration these values were 162.6 and 56.0 lbs. From the recorded data the author calculates that it required from 3 to 6 per cent more digestible and dry matter to make milk and milk ingredients with the molasses-beet-pulp ration than with the corn-meal ration. The proper method of feeding molasses-beet-pulp is discussed and rations including this material suggested. The author notes that successful results were not obtained when the attempt was made to feed molasses-beet-pulp to pigs, the animals uniformly refusing it. Among the conclusions drawn regarding molasses-beet-pulp were the following:

"It keeps well, will absorb large quantities of added water, has a slightly laxative effect, has proved a palatable and healthful food for dairy stock and satisfactory as a

component of a grain ration for the production of milk. It can also probably be used with good results for fattening and as a partial grain feed for horses.

"Because of its coarse mechanical condition, it will serve as a diluter for the heavier concentrates.

"It is rather inferior in nutritive effect to corn meal (probably 10 per cent)."

Feeding beet molasses and pulp to sheep and steers, L. A. MERRILL and R. W. CLARK (*Utah Sta. Bul. 90, pp. 51–65, fig. 1*).—The experience of some of the experiment stations and of private individuals in feeding beet molasses and pulp to farm animals is summarized, and tests with 6 lots of 2 steers and 6 lots of 16 sheep reported. The rations fed the sheep and steers were the same. One lot was fed alfalfa hay with beet pulp ad libitum. All the others were fed alfalfa hay with bran and shorts, the amounts varying in different cases. With 3 of the lots this ration was supplemented by beet pulp ad libitum and with the remaining lot by molasses (8 lbs. per head per day).

In the case of the steers the average daily gain per head ranged from 1.48 lbs. on a ration of alfalfa hay and beet pulp ad libitum to 2.26 lbs. on the alfalfa hay and bran and shorts, with beet pulp ad libitum. The dry matter eaten per pound of gain ranged from 8.87 lbs. in the case of one of the lots fed bran and shorts and beet pulp ad libitum with a limited amount of alfalfa hay to 13.05 lbs. on alfalfa hay and beet pulp ad libitum. The cost of a pound of gain ranged from 2.8 cts. on alfalfa hay and beet pulp to 4.93 cts. on alfalfa hay and bran and shorts.

In the case of the sheep the gains in weight ranged from 0.07 lb. per head per day on alfalfa hay with beet pulp ad libitum to 0.2 lb. on alfalfa hay with bran and shorts and beet pulp ad libitum, and the dry matter eaten per pound of gain from 8.5 lbs. on alfalfa hay with a limited amount of bran and shorts and beet pulp ad libitum to 18.06 lbs. on alfalfa hay and beet pulp ad libitum. The cost of a pound of gain ranged from 3.11 cts. in the case of the lot fed the ration containing a limited amount of bran and shorts to 5.17 cts. with the lot fed a limited amount of alfalfa hay with bran and shorts and beet pulp ad libitum.

The authors note that, when slaughtered, the steers fed beet pulp ad libitum with alfalfa hay and bran and shorts produced the best quality of meat. The loin was heaviest and the flesh fairly well marbled, firm, and juicy. The sheep fed the largest quantity of grain gave the best carcasses, but with them the profit was less than with those receiving little or no grain. Some of the authors' conclusions follow:

"Molasses fed to steers had a value of $2.35 per ton. As a sheep food it did not give the results expected. Beet pulp when fed to steers with grain and lucern had a value of from $1.66 to $2.54 per ton, and when fed to sheep its value ranged from $1.08 to $3.66 per ton. Steers that received grain made larger and cheaper gains and required less dry matter per pound of gain the latter part of the feeding period than the fore part. Steers which received only lucern and pulp made practically as good gains the fore part of the feeding period as the latter part."

A number of rations for steers composed largely of home-grown feeding stuffs are suggested.

Feeding teers, E. B. FERRIS (*Mississippi Sta. Bul. 83, pp. 1–4*).—The author states that steers pastured for 94 days during the winter on 5 acres for the purpose of manuring the land were kept at a loss. The average daily gain of the 28 animals was about 1.9 lbs. per head. One steer died as a result, it is thought, of eating poison ivy. The parking of the cattle on the light sandy soil of the substation enriched the land and improved its water-holding capacity in a very satisfactory manner.

Experiments in feeding steers, D. H. OTIS (*Kansas Sta. Bul. 124, pp. 1–30, pls. 19*).—The relative gains made by cattle of different ages were studied, calves 6 months old, yearlings, 2-year-old and 3-year-old steers being fed a ration of alfalfa hay, corn, and Kafir corn. The lot of calves contained 19 animals and all the other

lots 20 animals. In the 210 days covered by the test the gains ranged from 376 lbs. per head with the calves to 430 lbs. with the 3-year-old steers. The greatest range in the grain required per pound of gain was also found with these 2 lots, being from 5.44 lbs. to 7.94 lbs. A pound of gain was most cheaply made by the yearlings, costing in this case 5.03 cts., and was most expensive with the 3-year-old steers, costing 5.95 cts.

A lot of 10 2-year-old steers was fed corn silage, alfalfa hay, corn, and Kafir corn and a similar lot Kafir-corn stover, corn, and Kafir corn. With the former lot the total gain per head was 447 lbs. and with the latter lot 361 lbs., the grain eaten per pound of gain in the 2 cases being 6.7 lbs. and 10.1 lbs., and the cost of a pound of gain 4.91 cts. and 6.68 cts.

The author notes that with all the lots mentioned 4 lbs. of grain per 1,000 lbs. live weight was fed at the beginning of the test and the amount very gradually increased, the steers being on full feed in about 5 weeks. "There seemed to be no difference in the various lots as to the time required to get on full feed." All the animals were sold and slaughtered, data regarding the shrinkage in weight, dressing, etc., being recorded.

"The ensilage lot sold for the same price [$4.95] as the 3-year-olds, which is 25 cts. per hundredweight higher than the 20 2-year-olds fed without ensilage, but which were of the same class and quality when placed in the feed lots, and 45 cts. per hundredweight higher than the lot receiving Kafir-corn stover." The 3-year-olds showed the greatest shrinkage in hides, and the calves next. The shrinkage of hides in the other 4 lots was exactly the same. The carcasses of the ensilage lot contained the largest percentage of fat and, according to the author, were of good quality. The carcasses of the lot fed Kafir corn resembled those of grass-fed cattle. "They were fairly well fleshed, but not well covered with fat." Taking into account the total cost the calves were considered more desirable than the yearlings, though neither lot was fat enough. The 2-year-old steers were considered in very fair market condition.

The results of the test, as a whole, show that, "by feeding plenty of nitrogenous roughness (like alfalfa) and plenty of succulence (most cheaply obtained in corn ensilage), it is possible to make rapid gains and at the same time put the steers in prime condition for market.

"The results further emphasize the superior and economic value of alfalfa hay. Corn or Kafir-corn stover does not contain the nutrients required by the steer in securing best results unless the grain ration is supplemented with nitrogenous concentrates like oil meal or cotton-seed meal, which is usually costly.

"Since alfalfa is such a splendid feed, is a heavy yielder and a good drought resister, its growth can not be urged too strongly as an economical producer of beef, as well as other classes of stock which relish and thrive upon it. Alfalfa and ensilage combined furnishes a feed that can almost invariably be depended upon, no matter what the season is, and when grain fails will keep stock in good condition; and when grain is available will enable the feeder to put on gains rapidly with a comparatively small allowance of grain."

Feeding cattle with different quantities of concentrated foods (*Mark Lane Express, 91 (1904), No. 3799, Sup., pp. VII, VIII*).—Brief notes are given regarding a test at the University College of North Wales of the comparative value of limited and liberal rations of grain (maize meal and decorticated cotton-seed cake or linseed cake) in addition to pulped swedes, hay, and straw.

On the more liberal ration the average daily gain in the 50 days of the test was 2.55 lbs. per steer as compared with 2.37 lbs. on the limited ration. Taking into account the cost of food, the conclusion was reached that the extra gain did not compensate for the extra feed. Though the animals receiving the more generous ration were somewhat better in appearance than the others, the difference between

the 2 lots was not regarded as sufficiently marked to affect their relative money values.

Calf-feeding experiments with skim milk, V. JONSON (*Nord. Mejeri Tidn., 19 (1904), No. 16, pp. 208, 209*).—The results of an experiment with 8 calves here reported indicate that calves will give better returns for skim milk than pigs do.—F. W. WOLL.

Breeding and feeding pigs, D. H. OTIS (*Kansas Sta. Bul. 124, pp. 31–57, pls. 33*).—A number of points regarding feeding, breeding, etc., were studied with the station herd. Ten pigs on rape pasture (1 acre) made an average daily gain of 1.09 lbs. for 98 days, consuming 3.01 lbs. of grain per pound of gain. With a similar lot on alfalfa pasture (0.5 acre) the corresponding values were 1.10 lbs. and 3 lbs., and with a lot fed grain without pasturage 1.04 lbs. and 3.71 lbs. "The pasture is not only economical from the standpoint of gains, but it furnishes succulence and variety and keeps the hogs in a healthier condition."

When alfalfa hay was fed with grain to a lot of 12 pigs for 56 days the average daily gain was 1.2 lbs. per head and the grain eaten per pound of gain 4.65 lbs. In the case of a similar lot fed grain without hay the gain was 1.18 lbs. and the grain eaten per pound of gain 5.29 lbs.

Skim milk and buttermilk were compared with 3 lots of 6 pigs each fed respectively grain, grain with alfalfa pasturage, and grain with rape pasturage. With skim milk the average daily gain in the 77 days of the test was 1.12 lbs. and with buttermilk 1.06 lbs., the grain eaten per pound of gain being 3.11 lbs. and 3.31 lbs.

The influence of liberal feeding on runt pigs was tested with 4 animals. They were placed on rape pasture and fed a mixture of equal parts of corn, Kafir corn, and shorts, to which some dried blood and soy beans were added. In addition some grain was picked up behind steers. In the 278 days of the test the average daily gain was 0.94 lb., and the grain eaten per pound of gain 3.3 lbs. The author points out that the ration fed, together with good care, produced excellent results.

The gains made and the grain eaten by pure-bred and crossbred pigs were recorded, the best gains being made on an average at the lowest cost by the crossbred pigs, but as pointed out by the author it was not possible to include pigs of the same weight in all the lots. Some of the station's pure-bred and crossbred pigs were slaughtered and judged, but definite conclusions regarding breeds were not reached.

"Comparing the fat, medium, and lean hogs, there was found to be a great difference in the leaf lard. The sides from the lean hog were said . . . to make better bacon than the sides from the fat hog. The fat hog was considered to be more profitable from the butcher's standpoint, likewise from the breeder's standpoint, because they dressed a higher per cent. The medium hog was considered the best for bacon, but not as good as the lean hog for ham. From the butcher's standpoint the lean hog was the most unprofitable. The color of the meat was practically the same in the fat and medium hogs."

Observations are also recorded regarding the effect of size of litter on the gains made and upon the feed consumed by the dam, the effect of the age of dam on the size of litters, and the effect of following steers on the size of litters. The station dipping vat and farrowing houses are described.

Experiments in pig feeding, H. T. FRENCH (*Idaho Sta. Bul. 42, pp. 305–318, pls. 9, fig. 1*).—Several problems connected with pig feeding have been recently studied at the station. Using 2 lots, each made up of 3 Poland-China and 1 Tamworth-Poland-China, wet and dry feeds were compared for a period covering 119 days, the ration for about a month consisting of ground wheat and later of shorts and ground barley 1:2. The pigs fed the soaked grain made a total gain of 303 lbs., the grain eaten per pound of gain averaging 4.85 lbs. Those fed the dry grain gained 339.5 lbs., the grain required per pound of gain being 4.33 lbs. The author calls attention to the

fact that somewhat better gains were made on the dry ground grain, although in the majority of tests reported in this country a slight advantage has been noted with the soaked grain, especially when the grain was fed whole.

Using the same pigs as in the preceding test, the relative value of pure-bred and crossbred pigs was studied, the ration consisting of headed wheat fed ad libitum. In the 77 days of the test the average daily gain of the pure-bred pigs was 0.7 lb. and of the crossbred pigs 0.55 lb. The pigs were slaughtered and the live and dressed weight, weight of the organs, etc., recorded. On an average the shrinkage in the crossbred pigs was 23 per cent and in the pure-bred pigs 21 per cent. The author notes that no striking features were brought out by the slaughter test. The crossbred pork was considered superior for curing purposes, having a thinner rind, a larger percentage of lean, a more even distribution of fat, and a finer texture of meat fiber. In general the flesh of the crossbred pigs was leaner than that of the others and when cooked was regarded as of superior quality.

To learn something of the possibilities of feeding crossbred Tamworth-Poland-China pigs economically, a lot of 6 was fed for about a month soaked shorts, then for 2 months soaked chopped wheat, and for about a month chopped wheat and pea meal 1:2, the largest gain being made, according to the author, during the last period. In the 112 days covered by the test the average daily gain was 1.19 lbs. and the feed eaten per pound of gain 3.94 lbs. "The crossbred Tamworth-Poland-China pig for a bacon hog in our opinion is certainly a very desirable one. The pigs are thrifty from the time they are farrowed until matured." The estimated profit was $2.46 per 100 pounds live weight, not taking into account the cost of labor.

Using 9 pure-bred Poland-China pigs, the value of green peas as pasturage when supplemented by a ration of shorts and sweet separator skim milk was studied. The variety of peas selected was black-eyed marrowfats, sown May 22, and the pigs were turned on the pasture June 29. The test closed August 30, the pigs at this time having exhausted the pasturage on the one-fourth acre plat used. The average daily gain was 0.83 lb., the feed required per pound of gain being 2.15 lbs. of shorts and 4.43 lbs. of skim milk in addition to the pasturage. The author calculates that on the basis of this test an acre of peas converted into pork would be worth $59.56. "This, of course, is very large and could not be expected from any considerable area. . . . We have so far found the black-eyed marrowfat pea superior to the white Canada field pea, but conditions of soil will modify the results very much." The need of planting the peas deeply to avoid danger from drought is pointed out.

Peptone feed for pigs, W. Müller (*Fühling's Landw. Ztg., 53 (1904), No. 12, pp. 456, 457*).—Continuing earlier work (E. S. R., 15, p. 501), this brief note states that pigs given peptone feed in addition to potatoes and grain were fed at a greater profit than similar lots fed potatoes and grain only.

The nutrition of horses, J. B. Lindsey and P. H. Smith (*Massachusetts Sta. Bul. 99, pp. 11–16*).—Suitable feeding stuffs for horses, preparation of feed, watering, digestibility, and related topics are discussed and a number of rations suggested, some of which have been fed at experiment stations or by practical feeders.

"Generally speaking, 12 to 15 lbs. each of hay and grain daily are sufficient for horses of 1,200 to 1,300 lbs. weight doing moderately hard work. Should a portion of the grain consist of cotton seed, or gluten meal, it would be wise to reduce the grain ration somewhat and increase the quantity of hay. Farmers will naturally prefer to feed a maximum amount of hay and as small a quantity of grain as possible. In view of the high prices usually prevailing for oats, the feeder should aim to provide partial or entire substitutes for this grain. Mixtures of corn and bran, or corn, brewers' grains, and bran, ought to prove quite satisfactory."

Feeding horses and mules on home-grown feed stuffs, C. M. Connor (*Florida Sta. Bul. 72, pp. 115–126*).—The value of sweet potatoes, cassava, and of cane sirup as a partial substitute for corn in a ration for horses and mules was studied.

In the test with sweet potatoes 2 pairs of horses and 2 of mules, doing hard work, were used, one animal of each pair being fed corn, hay, and sweet potatoes in about the proportion of 6 lbs. of corn, 17 lbs. of hay, and 15 lbs. of sweet potatoes per 1,000 lbs. live weight, the other animal in each case receiving corn and hay only in about the proportion of 10 lbs. of corn and 15 lbs. of hay per 1,000 lbs. After 6 weeks the rations were reversed. The hay used was beggar weed of good quality. There was little variation in the weight of the animals, except that in 2 cases there was some increase when sweet potatoes were fed. In general, the sweet-potato ration was the cheaper.

"The most important fact brought out in this experiment is that sweet potatoes may be substituted for at least one-half of the corn ration, this substitution being at the rate of 3 lbs. of sweet potatoes for one of corn. This being the case, an acre of sweet potatoes yielding 150 bu. is equal to a yield of 50 bu. of corn, so far as feeding the work stock is concerned. We do not think that a horse at hard work would do well on an all sweet-potato ration from the fact that the bulk would be too great for the capacity of the stomach. . . . We have fed one mule for 3 months on sweet potatoes, cassava, and hay with good results. He was used for light work about the lot, such as hauling feed, bedding, etc."

Using 1 pair each of the mules and horses included in the previous test, the value of cassava was studied, one animal of each pair being fed cassava with corn and beggar-weed hay for 6 weeks, and the others corn and hay. The average amount of cassava eaten was irregular and in general smaller than in the case of sweet potatoes. "The animals maintained their weights throughout the experiment, which may go to show that cassava is more concentrated than the sweet potatoes. . . . Cassava may be used in about the same ratio as sweet potatoes, but is not so palatable to the animal."

At the close of the cassava test one of the mules was fed for 6 weeks a ration of corn and low-grade cane sirup and another the regular corn ration. The amount of hay eaten was not recorded, but the author states that it was about the same as in the previous tests. Small gains were made on both rations. "Both mules remained in good condition during this experiment in spite of the fact that they were doing hard plowing throughout the entire time."

The author states that sirup has been further tested in a preliminary way at the station and "that it is relished by all farm animals. In feeding, the sirup was given at night and morning and a larger corn ration given at noon. . . . Sirup may be fed to the work stock, provided it is mixed with chopped hay or something to give it bulk." As regards native hay for draft horses and mules, the author notes that considerable prejudice is felt regarding it by livery-stable men and in log camps. In his experience it has been used exclusively for 2 years, and he has never had any cause to regret its use. The chemical analysis of some of our native grasses is higher than that of timothy, "which is used almost exclusively in feeding horses."

Spanish goats, J. Crepin (*Jour. Agr. Prat., n. ser., 7 (1904), No. 18, pp. 587–591, pl. 1*).—A descriptive article including among other matters data regarding the chemical composition of milk of different sorts of goats.

Phosphated fowls, H. d'Anchald (*Jour. Agr. Prat., n. ser., 7 (1904), No. 19, p. 619*).—In an article quoted from the *Journal de la Société Royale Agricole de l'Est de la Belgique*, a test is reported in which an ordinary poultry ration was fed for 120 days in comparison with the same ration plus 4 gm. of powdered bone per day. The live and dressed weight of the chickens thus fed and the weight of the bones and organs are recorded.

The chicken fed the ground bone weighed 2.69 kg., while that fed the ordinary ration weighed 2.47 kg. The skeleton of the chicken fed ground bone weighed 0.236 kg. and that of the other 0.190 kg.

Cooperative egg and poultry societies (*Bd. Agr. and Fisheries* [*London*], *Leaflet 111, pp. 4*).—The work of the cooperative poultry societies in England and Ireland is briefly described, and the advantages which attend such organized attempts to benefit the poultry industry are briefly spoken of.

Duck breeding at Netherby, C. J. CORNISH (*Country Life* [*London*], *16* (*1904*), *Nos. 392, pp. 49–52; 393, pp. 99–101, figs. 13*).—The possibilities of raising teal, pintails, widgeons, and hybrid wild ducks in semicaptivity are discussed, and the results of experiments reported, which were on the whole successful, the whole question being considered from the standpoint of the possibility of stocking estates with game.

Experimental studies in oyster propagation, 1903, J. NELSON (*New Jersey Stas. Rpt. 1903, pp. 415–458, pls. 4*).—During the present year the studies in oyster propagation have had to do especially with the ventilation, temperature, and manipulation of the oyster spawn.

"We may summarize the factors or conditions on which success seems to depend, as determined up to the present, thus: Oysters freshly tonged, filled with spawn, consisting of ripe, clean eggs, speedily taken and fertilized, without crowding, by a small quantity of motile sperms, in well-filtered, fresh sea water taken at full flood-tide, thorough washing of the eggs, occasional agitation and good ventilation while keeping them at a temperature as near 75° as possible, with care to prevent their exposure to temperatures below 60° or above 80°. A failure in one or more of these respects proves fatal. Under the above conditions, if the fry do not reach the shell stage on the third day, counting the day of fertilization as first, it is evidence that an unknown factor foredooming to failure has influenced the experiment."

DAIRY FARMING—DAIRYING.

Report of the dairy husbandman, C. B. LANE (*New Jersey Stas. Rpt. 1903, pp. 347–411, pls. 25*).—This report deals with the soiling crops grown for the dairy herd, the record of the herd, cost of milk production, etc.

Soiling crops, 1903 (pp. 350–362).—The record is given of the yields of the various soiling crops grown for the dairy herd, the time during which they furnished feed, and the cost of production. Rye and wheat, while they did not give a large yield, supplied forage for the herd at a time when nothing else was available, and the land was immediately seeded to other crops. A record of one acre of alfalfa for 5 years showed an average yield of green forage of 19.32 tons per year, including the year it was seeded. Another acre seeded in May, 1901, yielded 11.36 tons, and a third plat yielded from 4 cuttings at the rate of 21.36 tons of green forage per acre. Crimson clover is regarded as "a very valuable plant for early forage," and peas and oats are "now considered almost a necessity by dairymen who practice the soiling system." If sown the first week in April, the crop supplies the best of forage during the month of June. The crop will not do well where the soil is acid, and hence a dressing of lime is recommended, and also a heavy dressing of well-rotted barnyard manure.

From tests of a number of varieties of millet it is concluded that "White French, Hungarian, Red Siberian, Golden, and German are not as profitable as the Barnyard (Giant) and Pearl (Pencilaria), where the object is to grow the largest amount of forage possible. Some of these varieties may, however, be better adapted for hay. Of the two other distinct varieties, namely, Barnyard and Pearl, the Barnyard has given better results as an all-around crop for the reason that it contains a higher percentage of dry matter and produces smaller and more palatable plants."

Among the cowpeas, the Red Ripper proved the best of the erect varieties and outyielded all the others; the Southdown, Small Black, and Taylor (medium trailers) also being noted as good. The Thoroughbred White Flint corn continues to be one of the best kinds for soiling purposes, owing to its succulent habit and heavy growth. Strychnin mixed with moist corn, which was then spread upon the field, proved

very efficient in destroying blackbirds which had been troublesome in the corn fields.

The arrangement of soiling crops during the season of 1903, so as to furnish a continuous supply of forage for the dairy herd from May 1 to October 20, is tabulated, together with the yields per acre of green material and of nutrients. "The total yield per acre for all crops in the year's rotation shows a profitable return. Leaving out of consideration the crops that were turned under, and the mixed grasses, which were not in the regular rotation, 6 acres yielded less than 10 tons, 11 acres yielded more than 10 tons and less than 15, 4 yielded over 15 and less than 20, while one yielded over 20 tons. The average yield per acre for the crops in the regular rotations, not including those turned under, was 12.15 tons."

Forage v. silage (pp. 363, 364).—For 7 years past the coarse fodder has consisted of soiling crops from May to November, and of silage for the remaining 6 months. A summary of the records of the dairy herd for that period "shows the average yield of milk per cow during the soiling and silage periods to be 3,402 and 3,024 lbs., respectively, a difference of 378 lbs. in favor of soiling. The average yield of butter was 171.3 lbs. for the soiling period and 154.5 for the silage period, a difference of 16.8 lbs., also in favor of soiling. The average percentage of fat for the two periods was practically the same." The number of fresh cows each month during the year was quite uniform, so that the comparison was thought to be a fair one.

Experiments with nitrate of soda on mixed grasses, rye, wheat, barley, cowpeas, and millet (pp. 364, 365).—The use of nitrate of soda at the rate of 150 to 200 lbs. per acre was accompanied by a gain in yield, ranging from 0.7 ton in the case of barley to 1.7 tons for rye, and a financial gain ranging from $1.55 on barley to $2.23 on wheat. The nitrate was most effective when applied early in the season on early crops.

Seeding grass on sod without grain (p. 365).—This practice, which is not a common one among farmers, has proved an excellent one at the station. There has never been failure to secure a good stand.

Inoculation experiments with alfalfa (pp. 366–374).—These experiments were carried on in 45 small cylinders sunk in the ground. Typical soils were obtained from 8 different localities, and these were inoculated with soil and with soil infusion. In other cases the soil was not inoculated, but received a dressing of nitrate of soda at the rate of 147 lbs. per acre. The conclusions from the first year of the experiment were as follows:

"(1) Inoculation with alfalfa bacteria in 'soil solution' and in 'soil' produced an average gain of 40.2 and 9.1 per cent, respectively, in two crops of alfalfa, over cylinders not inoculated.

"(2) All soils did not respond alike to inoculation. A variation of 0 to 83 per cent was noted in case of inoculation with 'soil solution,' and 30.7 to 43.9 per cent where the inoculation was made with 'soil.' It should be noted, however, that in the latter instance the loss of 30.7 per cent was due, in part at least, to a poor stand of alfalfa.

"(3) A wide variation was found in the natural adaptability of soils in different parts of New Jersey for growing alfalfa. A difference of 118 per cent was noted in groups of cylinders containing the different kinds of soil.

"(4) Cylinders inoculated with 'soil solution' produced 11.1 per cent more alfalfa the first season than those treated with nitrate of soda at the rate of 147 lbs. per acre, costing $3.31."

Cost of producing milk (pp. 374–377).—During the year ended April 1, 1903, the herd of 34 cows consumed grain feed to the amount of $836.85 and coarse fodder amounting to $648.80, making a total cost of food for the year of $1,485.65, an average of 11.97 cts. per cow daily. The cost of the grain feed represents what was actually paid for it; that of the hay, cornstalks, and soiling crops represents the actual cost of labor,

seed, manures, and fertilizers, the farm manures being charged at the rate of $1.50 per ton. The total yield of milk by the herd was 98,574 qt., and the cost of the feed (grain and coarse fodder) per quart of milk was 1.51 cts. The total cost of producing milk, including the cost of feed, of labor, and the interest on and decrease in the value of the herd, amounted to 2.26 cts. per quart, or $1.03 per 100 lbs. "At $1 per hundred, the price received in many rural districts, the profits from the business, if any, must be found in the manure." Allowing $1.50 per ton for the manure, in this case there would be a profit of $482.26 from the 34 cows under the soiling system.

At 3½ cts. per quart for the milk, the price which could have been received at wholesale, the receipts would have amounted to $3,450.09; deducting from this the cost of the purchased feeds, labor, interest, decrease in herd, etc., would leave a balance of $1,877.24, which would represent the value of the home-grown crops. Assuming that the dairyman does his own work, another calculation is made.

Summarizing the record of the dairy herd for 7 years, "the average yield per cow was 6,528 lbs. The average cost of food per cow per day was 12.35 cts., of which 6.41 cts., or 51.9 per cent., represents purchased feeds and 5.94 cts., or 48.1 per cent, farm crops. The average cost per quart of milk for the seven years, including food, labor, and interest and decrease in the value of the herd, is shown to be 2.37 cts."

The dairy business in relation to soil exhaustion (pp. 377–379).—Tables are presented showing the amount of fertilizing elements contained in the feeds purchased and in the milk produced by the herd for 7 years, and bring out "a decided gain to the farm in all the elements of fertility each year." It is shown that if all the milk sold from the farm was obtained from foods grown on the farm, the exhaustion of nitrogen would be in greater proportion than of the mineral elements, and that it would be necessary to supply nitrogenous fertilizers in order to maintain the fertility.

Records of the dairy herd (pp. 380–387).—The monthly record is given for each cow for the year ended April 1, 1903, and from this record and the average composition of the milk the yield of butter is calculated. The best cow produced 8,511.3 lbs. of milk and the poorest cow 3,482.4 lbs., the average being 5,952.6 lbs. In butter production the best cow produced 414.96 lbs. and the poorest 183.25 lbs., the average for the herd being 302.4 lbs.

"As in previous years, the facts brought out by this study indicate that but little if any profit can be derived from a cow that does not produce 5,000 lbs. of milk per year, particularly if the milk is sold at the low price of 1 ct. per pound. . . . The 14 cows yielding over 300 lbs. of butter paid for their food and $25.51, in addition to skim milk and manure; while the manure and skim milk of the 12 cows yielding less than 300 lbs. of butter represent the pay received for their care and the labor of making the butter, with $6.11 additional."

A study of the waste in handling and delivering milk during 7 years showed a steady decrease, which in 1903 amounted to only 0.16 per cent. The decreased waste is due largely to improved apparatus and greater care in handling the product. "While the use of bottles increases the expense of delivery, due to extra weight on the wagon, the extra work of cleaning and the breakage and loss of bottles, which amounts to about 10 cts. per day for each 100 used, the decrease in waste, greater cleanliness and better condition of the milk when delivered has more than offset this extra cost."

Cowpea hay v. purchased feeds (pp. 388–396).—In this experiment, which included 4 cows and continued for 36 days, 17 lbs. of cowpea hay was compared with a grain ration of 4 lbs. of wheat bran, 3 lbs. of dried brewers' grains, and 2 lbs. of cotton-seed meal, 36 lbs. of corn silage being fed with each ration. During the experiment 8.3 per cent more milk and 15.2 per cent more butter were produced upon the grain than on the cowpea-hay ration, and all the cows tested higher in milk fat on that ration. The cost of feed to produce 100 lbs. of milk was 39.8 cts. on the cowpea-hay

ration, and 60.5 cts. on the grain ration, and the cost of a pound of butter 8.82 and 12.06 cts., respectively.

Soy-bean silage and alfalfa hay v. purchased feed (pp. 396–402).—In this experiment 4 cows were fed for two 15-day periods to compare a ration of 36 lbs. of soy-bean silage, 8 lbs. of alfalfa hay, and 6 lbs. of corn meal, with one composed of 6 lbs. of cornstalks, 36 lbs of corn silage, 4 lbs each of wheat bran and dried brewers' grains, and 2 lbs. of cotton-seed meal. On the soy-bean silage and alfalfa-hay ration 5.81 per cent more milk was produced than on the grain and silage ration, while the yield of butter was practically the same on the 2 rations. There was a saving of 8.5 cts. per hundred in the cost of producing milk, and 1.1 cts. per pound in the production of butter when the soy-bean silage and alfalfa-hay ration was fed.

"These data are significant in showing not only the value of such home-grown crops as soy-bean silage and alfalfa hay, but also that a ration may be produced on the farm that is quite superior as a milk producer to one in which the fine feeds are purchased; at the same time it is furnished at less cost."

Cotton-seed meal v. wheat bran and dried brewers' grains (pp. 402–411).—A grain ration consisting of 4½ lbs. of cotton-seed meal was compared with one composed of 5 lbs. each of wheat bran and dried brewers' grains, 36 lbs. of corn silage and 6 lbs. of cornstalks being fed with each ration. The feeding covered 4 periods, 2 lots of 2 cows each being used.

The summary of the results shows that the amount of milk and butter produced from the 2 rations was practically the same. The cost of food per 100 lbs. of milk was 54.1 cts. on the cotton-seed meal ration and 66 cts. on the mixed grain; and of butter 11 cts. and 14.3 cts., respectively. "In other words, the results indicate that when dried grains cost $20 and wheat bran $21 per ton, the dairyman can afford to pay $42 per ton for cotton-seed meal when producing milk."

Cooperative experiments with milch cows, 1902–3, H. Goldschmidt, C. M. Kjeldsen, and J. A. Lemming (*Copenhagen, 1903, pp. 52+XVI, charts 16*).—This is an account of the first series of cooperative feeding experiments with milch cows conducted on 13 Danish dairy farms for the purpose of studying the economy and the effect on the milk production of introducing certain changes in normal feed rations met with in Danish feeding practice, in such a way that an increase or a decrease of either protein or nonnitrogenous components of the rations was supplied. The elaborate plan of the experiments and details as to their conduct are given in the report; but only a brief statement as to the main conclusions drawn by the authors can be given here.

The normal rations fed consisted of a basal portion of 0.7 lb. digestible protein and 7 lbs. calculated digestible carbohydrates (nitrogen-free extract + fat × 2.4) per 1,000 lbs. live weight, and a productive portion of 0.55 lb. of digestible protein and 1.3 lbs. digestible carbohydrates per 10 lbs. milk. This ration was found somewhat too high in both protein and carbohydrates to prove the most profitable, but on the whole may be considered a satisfactory guide to the feeder. The experiments illustrate plainly the economy of feeding in accordance with the amount of milk produced by the cows at the different stages of the period of lactation.—F. W. WOLL.

The dairy, J. Mahon (*Queensland Dept. Agr. Rpt. 1904, pp. 30–33*).—Data are given regarding the milk and butter yield of the station cattle, and a test on the feeding value of white carrots for dairy cattle is reported.

Investigations on the electrical resistance of milk, F. Petersen (*Milch Ztg., 33 (1904), No. 36, pp. 567, 568*).—The main results of the investigation may be stated as follows: The electrical resistance of normal cow's milk is dependent on its composition and on the temperature of the milk, falling with rising temperature, and vice versa. The average resistance of milk from single cows was found to range between 186 and 304 ohms at 15° C., and averaging 231.64 ohms; while that of mixed-herd milk fell between 204 and 255 ohms at 15° C.

The resistance seems to depend on individual peculiarities of the cows, other than their age or the stage of the period of lactation. It is, however, greatly increased in the milk of strippers during the last month of the lactation period, and is considerably below normal in colostrum milk, during the first days after calving. It increases rapidly from this time up to the tenth or twelfth day, after which time it again falls, and varies within the ordinary limits. The resistance of the milk increases with the progress of the act of milking, the strippings having the highest resistance of any portion of the milking.

So long as the milk does not sour its electrical resistance remains constant, but no direct correlation was found in the case of new milk between the degree of acidity of the milk, as obtained by titration with an alkali solution, using phenolphthalein as an indicator, and the electrical resistance of the milk. No difference in the resistance was observed between milk produced on pasture and that produced on dry feed, nor does there appear to be any breed characteristic in this respect.

The general average of 660 single determinations of the electrical resistance of cow's milk was 232 ohms, with a probable error of 14.28 per cent. The addition of water increases the electrical resistance of milk, although the results are not decisive when only small quantities of water are added. With the addition of 10 per cent of well water, the probability of adulteration, as shown by the results of the author, is 0.522; with 20 per cent, 0.881; with 30 per cent, 0.991, and with 40 per cent, 0.9996. There is no correlation between the resistance of milk and its specific gravity, or its content of total solids, nor does any direct correlation exist with the ash content of the milk, although a certain parallelism is apparent, especially when the ash content of the nonfatty solids is compared with the figures for the resistance of the milk.

All the milk components conducting electricity are present in the milk serum passing through a porous filter, while milk freed from its mineral components no longer conducts electricity. The electrical conductivity of the milk depends primarily on the ash of the milk, especially on the chlorids, and next on the phosphates and sulphates.—F. W. WOLL.

Splitting up of fat globules in cows' milk on agitation, C. BARTHEL (*Nord. Mejeri Tidn., 19 (1904), No. 25, pp. 331, 332*).—The author determined, by means of the Babcock method, the number of fat globules in milk before and after heating to 55° C., and churning the same for 5 to 90 minutes in a Holstein churn, run at the normal rate. An increase in the number of globules in 1 cu. mm. of milk was observed in every case when the milk had been heated and churned, the increase being larger the longer the milk was churned. While the Gottlieb method gave identical results in the case of all samples of milk, the fat content obtained by the Adams method decreased with increasing length of time churned. The following series of trials illustrates the relations observed:

Relation between length of churning and number of globules.

	Number of globules in 1 cubic millimeter.	Fat content.		Difference.
		Gottlieb.	Adams.	
		Per cent.	*Per cent.*	*Per cent.*
New milk	2,800,000	3.87	3.88	0.01
Churned 5 minutes	4,180,000	3.68	3.88	.20
Churned 10 minutes	4,800,000	3.59	3.86	.27
Churned 15 minutes	6,600,000	3.52	3.86	.34
Churned 30 minutes	10,360,000	3.49	3.88	.39
Churned 60 minutes	10,650,000	3.39	3.88	.49
Churned 90 minutes	11,000,000	3.36	3.88	.52

—F. W. WOLL.

On fat determinations in separator skim milk and buttermilk, E. HOLM (*Mälkeritid., 17 (1904), No. 14, pp. 260–262*).—A discussion of the relative merits of

the ether-extraction and the Gottlieb methods of fat determination. The author corroborates the results obtained by Barthel (E. S. R., 15, p. 1053), showing that the extraction method will give too low results in the case of milk that has been churned or subjected to considerable agitation at a temperature over 40° C.—F. W. WOLL.

Sin-acid butyrometry (*Milch Ztg., 33 (1904), No. 27–28, pp. 417–419, 436–438*).—A general description of a new method of milk analysis devised by A. Sichler, in which the nonfatty solids are brought into solution by a salt solution, the composition of which is withheld from publication. The bottles used in this method are somewhat similar to the Gerber milk-test bottles. It is accurate in comparison with the Soxhlet and Gerber methods, and is claimed to be very simple in manipulation.—F. W. WOLL.

The bacterial contamination of milk and its control, F. C. HARRISON (*Trans. Canad. Inst.; 7 (1904), III, No. 15, pp. 467–496, figs. 17*).—Practically the same as a paper abstracted from another source (E. S. R., 15, p. 183).

New bacterial species giving the aroma to butter, SEVERIN (*Messenger Imp. Russ. Soc. Acclim. Animals and Plants, No. 11, pp. 8–14; abs. in Zhur. Opuitn. Agron. [Jour. Expt. Landw.], 5 (1904), No. 3, p. 415*).—The bacterium which imparts to butter the peculiar agreeable aroma is described. The experiments on the practical application of this bacterium have not yet been concluded.—P. FIREMAN.

Comparative study of the bacterial flora of Russian-Swiss and Emmenthaler cheeses, BUDINOV (*Messenger Imp. Russ. Soc. Acclim. Animals and Plants, No. 11, pp. 15–38; abs. in Zhur. Opuitn. Agron. [Jour. Expt. Landw.], 5 (1904), No. 3, p. 414*).—Results of 3 complete analyses are given of two Russian-Swiss cheeses (one young and one 3 years old) and one Emmenthaler cheese. In the young Russian-Swiss cheese were found 3 species of bacteria (2 cocci and 1 bacillus), and in the Emmenthaler 6 (3 cocci and 3 bacilli). The rind proved to be in both cases poorer in bacteria than the cheese itself. The 3-year-old cheese was found entirely sterile. All the bacteria isolated were lactic-acid formers and are facultative anaerobic organisms.—P. FIREMAN.

Contributions from Dr. Johan-Olsen's dairy bacteriological laboratory, G. TROILI-PETERSON (*Nord. Mejeri Tidn., 19 (1904), No. 23, pp. 305, 306*).—A description of the method of pure yeast culture of Johan-Olsen used in the manufacture of the Norwegian cheeses Gammelost and Pultost.—F. W. WOLL.

The manufacture of dried milk, R. CROWE (*Jour. Dept. Agr. Victoria, 2 (1904), No. 9, pp. 934, 935*).—The manufacture of dried milk on an experimental scale by a local firm is described. It is said that the resulting milk powder may be mixed with water and used in the same way as ordinary milk.

Milk powder; a new industry, H. VANDERYST (*Rev. Gén. Agron. [Louvain], 13 (1904), No. 5, pp. 233–239*).—A summary of data regarding the manufacture of dried and powdered milk.

State milking courses of 1903, and what they have taught us, O. L. DANILS (*Nord. Mejeri Tidn., 19 (1904), No. 12, pp. 152–154*).—The beneficial effects of the milking courses conducted during the year 1903, which were arranged for by the Swedish government, are commented upon.—F. W. WOLL.

Oleomargarine legislation in Denmark and other countries, H. FABER (*Mälkeritid., 17 (1904), No. 23, pp. 415–430*).—F. W. WOLL.

VETERINARY SCIENCE AND PRACTICE.

Report of the State veterinarian, L. PEARSON (*Pennsylvania Dept. Agr. Rpt. 1903, pp. 87–158*).—The work of the office of the State veterinarian for 1903 is outlined in considerable detail. Copies are given of acts of the Pennsylvania legislature encouraging the repression of tuberculosis and preventing the spread of rabies.

A condensed statement is presented regarding the present status of glanders, anthrax, blackleg, hemorrhagic septicemia of cattle, rabies, forage poisoning of

horses, cowpox, hog cholera, mange in horses, infectious abortion in cows, milk fever, and tuberculosis. On account of the rapidity with which the symptoms of forage poisoning develop and the high rate of mortality in cases of this disease, the author mentions in some detail the conditions with regard to food and water under which this disease may develop to the greatest extent. Treatment of forage poisoning has thus far been rather unsatisfactory.

Tuberculosis still prevails in nearly all parts of Pennsylvania except the mountainous counties. Copies are given of the legal forms of requests for inspection and tuberculin tests of herds and for assistance in disposing of tuberculous cattle. The thorough application of the Bang method, or some modification of this method, is considered the most satisfactory way of eradicating this disease. Good results have thus far attended the experiments in vaccinating young cattle with attenuated tubercle bacilli in order to confer upon them further immunity to the disease. Further experiments along this line will be carried out.

Report of the veterinary service in the Kingdom of Saxony for 1903 (*Ber. Veterinärw. Königr. Sachsen, 48 (1903), pp. 348*).—This report contains an account of the organization of the veterinary service, brief reports from district veterinarians, an account of cattle and goat raising, a discussion of meat inspection, diseases of horses, and the work of the veterinary high school in the Kingdom of Saxony.

The influence of surra upon metabolic processes, R. STÄHELIN (*Arch. Hyg., 50 (1904), No. 1, pp. 77–96*).—In order to study the effect of surra upon the physiological processes of the animal body a dog was artificially inoculated with this disease. The dog had previously been studied for the purpose of determining as accurately as possible its normal digestion. The amount of nitrogen in the urine was found to be considerably less during the fever period, while the amount in the feces was increased.

During the progress of the disease increasing quantities of nitrogen and fat were decomposed. One of the most striking examples of inequality in the income and outgo was shown in the great excess of the water excreted over the quantity ingested.

Report on Bacillus violaceus manilæ, a pathogenic micro-organism, P. G. WOOLLEY (*Philippine Dept. Int., Bureau Govt. Labs.* [*Pub.*], *1904, No. 15, pp. 15, pl. 1*).—The bacillus described as new under the name *B. violaceus manilæ* was isolated from 3 carabaos which died so suddenly and with few well marked symptoms that hemorrhagic septicemia was suspected as the cause of death.

Cultures of the organism were obtained from the lymph glands and lungs. Inoculation of guinea pigs produced an infection similar to that observed in carabaos. In one case 1 cc. of a 48-hour-old culture caused the death of a guinea pig within 5 days after inoculation. The organism was found to be pathogenic also for dogs, calves, cats, and rabbits. A test undertaken to determine whether or not a soluble toxin was produced by the organism gave negative results. Dead cultures suspended in normal salt solution caused a reaction on the fifth day after the inoculation of a monkey. The blood of this animal then showed complete agglutinating power.

The penetrability of the intestinal wall for micro-organisms under physiological conditions, B. KLIMENKO (*Ztschr. Hyg. u. Infectionskrank., 48 (1904), No. 1, pp. 67–112*).—The literature relating to this subject is discussed in a critical manner in connection with bibliographical references. The author's experiments were made on dogs, guinea pigs, and rabbits, and the micro-organisms used in the experiments included *Bacillus prodigiosus, B. mesentericus vulgatus, B. kieliensis, B. pyocyaneus,* hay bacillus, acid-fast bacilli from butter, *Thyrothrix tenuis,* and *Staphylococcus citreus.*

As a result of numerous feeding experiments with these organisms under various conditions, it is concluded that the intact intestinal wall of perfectly healthy animals is not permeable for micro-organisms. The possibility is admitted of the penetration

of the intact intestinal wall in cases of general disease. Since, however, it is quite rare to find an animal in perfect health, and since the slightest pathological lesion in the animal organism, or even an insignificant mechanical injury to the mucous membrane of the alimentary tract, may make possible the penetration of bacteria, these facts must be considered of great practical significance. Apparently the organism may receive some protection against the penetration of micro-organisms from the mesenterial lymphatic glands.

The formation of antitoxins, C. BRUCK (*Ztschr. Hyg. u. Infectionskrank., 48 (1904), No. 1, pp. 113–120*).—The author's observations as reported in this article were largely confined to a study of tetanus toxin and toxoid in the organism of guinea pigs.

The results of experiments with the tetanus toxin and toxoid are presented in a detailed tabular form. From this study it appears that 3 stages may be recognized in the formation of antitoxins. In the first stage the haptophor group is formed in connection with the receptor. In the second stage there is an increased formation of receptors corresponding to the appearance of the haptophor group, and in the third stage the antitoxin proper appears as a result of a stimulus furnished by the presence of the toxophor group.

The validity of the law of multiple proportions in the reaction between toxin and antitoxin, L. MICHAELIS (*Biochem. Centbl., 3 (1904), No. 1, pp. 1–12*).—A careful study of the reaction between toxin and antitoxin indicates that the law of multiple proportions as understood in chemical reactions can not be strictly applied in this case. In all thoroughly investigated diseases a definite amount of antitoxin is required to fix or neutralize a given amount of toxin. A definite combination of toxin or antitoxin, however, does not take place readily, and for this reason variable quantities of each remain disassociated for some time.

Therapogen, W. FLATTEN (*Berlin. Tierärztl. Wchnschr., 1904, No. 38, pp. 637, 638*).—This is a new disinfectant which does not belong to the coal-tar series and therefore does not have the disagreeable odor of these products. Therapogen mixes readily with oils and does not injure metal instruments even when the latter are left in 20 per cent solutions for a period of 24 hours. It was shown by experiments to be strongly bactericidal for anthrax, glanders, typhoid, diphtheria bacilli, etc.

Test of plants supposed to be poisonous, W. H. HUTT (*Utah Sta. Rpt. 1903, pp. XXI, XXII*).—Samples were collected of wild hay which was said to be poisonous to cattle. An exam nation of hay showed that 3 plants were quite common in addition to grasses. These plants were *Smilacina stellata*, *Equisetum arvense*, and *Pastinaca sativa*. Samples of these weeds were obtained and fed to sheep without causing any poisonous effects to these animals.

The prevention of contagious pleuro-pneumonia, CONSTANT and MESNARD (*Rec. Méd. Vét., 81 (1904), No. 17, pp. 552–563*).—In previous experiments carried out by the authors, the fact was established that accidents following preventive inoculation for contagious pleuro-pneumonia usually depend upon the existence of a latent infection in the inoculated animals. The latent infection appears to cause, in conjunction with the inoculation, a localization of the virus. The duration of immunity produced by a single inoculation is at least 10½ months.

Further observations and experiments along this line are reported in the present paper. It was found that animals could be inoculated in the extremity of the tail with a small quantity of a virulent culture without producing serious consequences. Such inoculation, with doses of ⅛ cc. under proper antiseptic precautions, produces an immunity which exists for about 2 years. This method is recommended for practical application in the prevention of pleuro-pneumonia. In outbreaks of this disease the authors recommend the immediate destruction of infected animals and the inoculation of all exposed animals.

Some pulmonary lesions produced by the bacillus of hemorrhagic septicemia of carabaos, P. G. Woolley (*Philippine Dept. Int., Bureau Govt. Labs. [Pub.], 1903, No. 12, pp. 11*).—Hemorrhagic septicemia assumes a great variety of forms, some of which are described in this bulletin.

In one case in a carabao the symptoms were those of pleuro-pneumonia. Smears made from the blood, liver, lungs, and prescapular lymph glands showed considerable numbers of oval bacilli. In a second case, a post-mortem examination showed a subcutaneous edema on the sides. Cultures were made from abscesses on the lungs, and these organisms were pathogenic for monkeys, small birds, rabbits, and guinea pigs, whether inoculated subcutaneously, intravenously, or into the pleura and peritoneum. It does not appear to be clear how the bacillus of hemorrhagic septicemia gains entrance into the lungs.

Further experiments with parturient paresis (milk fever), C. B. Lane (*New Jersey Stas. Rpt. 1903, p. 380*).—Brief mention of the successful use of the Schmidt treatment in the case of one cow.

Comparative experiments on human and bovine tuberculosis, H. Preisz (*Ztschr. Tuberkulose u. Heilstättenw., 6 (1904), No. 3, pp. 221–230*).—Brief critical notes are given on literature relating to this subject. The author carried out a number of experiments in testing the effect of tubercle bacilli of human origin upon cattle. In one series of experiments 6 cattle were inoculated subcutaneously with human tubercle bacilli of mixed origin. In another set of experiments, 4 calves were inoculated intraperitoneally. In a third set of experiments 2 cows were inoculated intravenously, while in a fourth series 5 cattle were fed cultures from human tubercle bacilli.

Although 10 different races of human tubercle bacilli were used in these experiments, none was found which produced generalized tuberculosis of cattle. Among the 6 cattle which were inoculated subcutaneously the disease did not spread even to the neighboring lymphatic glands, except in one case. In a majority of cases large subcutaneous inoculations failed to produce even local alterations in the inoculated animals. Nevertheless, infection did occur in a few instances, and the author maintains, therefore, that considerable hesitancy should be felt in arguing in favor of a specific difference of these 2 forms of tubercle bacilli on account of the observed difference in virulence.

The transmissibility of human tubercle bacilli to animals, J. Karlinski (*Ztschr. Thiermed., 8 (1904), No. 6, pp. 401–416*).—The native cattle of Bosnia are known to be exceedingly resistant to the tubercle bacillus. Previous experiments of the author, however, had shown the possibility of infecting these cattle by means of human tubercle bacilli. In the present experiments native goats were selected as experimental animals.

Statistics from the inspection of meat of these animals showed that not a single case of tuberculosis had been discovered in 210,644 goat carcasses inspected. For the purpose of testing the resisting power of these goats 2 animals were inoculated intravenously with 5 cc. of an emulsion of human tubercle bacilli. The inoculation was performed in April, and in July both animals showed a pronounced reaction to tuberculin and considerable emaciation. The goats were killed and caseous foci were found in a majority of the mediastinal and tracheal lymphatic glands.

An extensive series of experiments was also carried out to determine the influence of inoculation with human tubercle bacilli upon pregnant goats. In these experiments 22 animals were used. Detailed notes are given on the results noted in each goat. It was found that the human tubercle bacilli were virulent in these experiments. The lymphatic apparatus was chiefly affected, while the lungs were more rarely attacked. The effect of inoculation was quite pronounced, as shown in the frequency with which abortion occurred. The transportation of the tubercle bacilli

into the milk was frequently observed in cases where no visible alteration of the udder was present.

The author also demonstrated by experiments that the virulence of human tubercle bacilli could be greatly increased by a single passage through goats. In another experiment one goat was inoculated intravenously with $\frac{1}{10}$ g. of a culture of avian tubercle bacilli. This goat was killed after a period of 5 months, at which time the tracheal glands were found to be enlarged, and caseous and tubercle bacilli were also found on the diaphragm and surface of the spleen.

Experiments with tuberculins made from human and bovine tubercle bacilli, S. B. Wolbach and H. C. Ernst (*Jour. Med. Research, 12 (1904), No. 3, pp. 295–311*).—The purpose of experiments reported in this article was to repeat the experiments of Koch with tuberculin on tuberculous guinea pigs, and to test the possibility of specific differences in tuberculins from human and bovine sources.

Cultures of tubercle bacilli were obtained directly from cases of the disease in man and cattle and were maintained on human and bovine blood. The virulence of the cultures were determined by the method of Theobald Smith, and the strength of the tuberculins by the method of Donitz. Guinea pigs were inoculated with this substance and subsequently treated with tuberculins. The detailed results of the experiments are reported in a tabular form. The local effect of tuberculin upon the abscess at the point of inoculation was the most marked action noted as a result of treatment with tuberculin. The abscess increased in size much more rapidly in the control animals, while in treated guinea pigs the abscess generally decreased in size and in a few cases healed. Autopsies made on the guinea pigs used in the experiments failed to show any differences in the character of the disease produced by human and bovine tubercle bacilli.

The authors conclude, therefore, that there is no specific difference between tuberculins from human and bovine sources, and that the tuberculin treatment acts somewhat favorably upon the development of tuberculosis in guinea pigs.

The channels of infection in tuberculosis in childhood, L. Kingsford (*Lancet [London], 1904, II, No. 13, pp. 889–892*).—The author presents an analysis of statistics relating to tuberculosis in children during the past 14 years. As a result of a study of these cases the author concludes that about 20 per cent were due to the ingestion of tuberculous material into the alimentary tract. It is stated that perhaps the danger from drinking tuberculous milk has been somewhat exaggerated, but the fact that 20 per cent of the cases of tuberculosis in children appear to arise from primary infection in the alimentary tract makes out a strong case against tuberculous milk.

Acclimatization to tuberculin, H. Vallée (*Ann. Inst. Pasteur, 18 (1904), No. 9, pp. 545–552*).—It has long been supposed that cattle may become nearly immune to the effects of tuberculin as a result of repeated injections. Numerous experiments along this line were carried out and reported by Nocard. The author instituted a series of experiments to test this acquired resisting power to the action of tuberculin.

It was found that, if the temperature be taken within 2 hours after the second injection of tuberculin and at intervals of 2 hours thereafter for 12 to 14 hours, the temperature curve may show a marked reaction. If, however, the temperature is first taken 12 hours after the injection the reaction may have entirely passed and the experimenter may thus fail to observe it. The author's experiments were carried out on 36 cattle, 32 of which could be definitely declared as tuberculous after the first tuberculin injection. The second tuberculin test was made 48 hours after the first, at which time 28 cattle gave a marked reaction and none of the others could be considered as free from tuberculosis. The temperature curves obtained by the author, however, show that the reaction to the second tuberculin inoculation is of very short duration as compared with that of the first.

On the basis of these experiments the author concludes that in a majority of cattle

there is never a true acclimatization to the effect of tuberculin, but that the reaction to a second tuberculin injection occurs so promptly and lasts so short a time that it is usually overlooked. In order to prevent any deception on the part of cattle vendors in making the tuberculin test, it is recommended that the inoculation be made about 5 or 6 o'clock a. m. and that approximately twice as large a dose be used as ordinarily, 8 cc. being considered a satisfactory dose for susceptible cattle. The temperature should then be taken at intervals of every 2 hours for a period of about 14 hours.

An experimental study on the effect of the blood sera of normal and immunized goats in modifying the progress of tuberculous infection, A. G. NICHOLLS (*Proc. and Trans. Roy. Soc. Canada, 2. ser., 9 (1903-4), IV, pp. 3-32*).—The first observations relating to the agency of blood serum in checking the progress of tuberculosis were published by Héricourt and Richet in 1888, since which time a number of experiments have been made by other investigators along similar lines. The author studied the properties of normal and immunized goat serum as related to the progress of tuberculosis.

It was found that goats are relatively quite immune to tuberculosis and that the normal blood serum of goats contains a correspondingly large number of antitoxic units. In the first series of experiments several guinea pigs and rabbits were inoculated with mildly virulent tubercle bacilli and also treated with normal goat serum. Detailed notes are given on the history of each of these cases. It was found that tubercle bacilli were not disseminated to a distance from the site of the original inoculation with any of the treated animals. A second series of experiments were made on another lot of guinea pigs and rabbits, which were inoculated with a more virulent culture of tubercle bacilli. In these cases injection of normal goat serum had no effect in checking the disease in guinea pigs, but in rabbits such a result was noticeable.

Since the blood of healthy goats appears to be considerably antitoxic, the author attempted to intensify this property by inoculating healthy goats with gradually increasing doses of Koch's new tuberculin. Experiments were then carried out in testing the effect of the serum of such goats upon the progress of tuberculosis in rabbits.

As a general result of the author's studies it is concluded that the injection of antitoxic goat serum exercises a certain amount of restraining influence upon the extent and development of tuberculosis. This influence, however, is not enough to prevent entirely the extension of the disease. Normal goat serum injected into guinea pigs and rabbits is almost harmless and rarely produces any hemolysis. It appears to stimulate the nutritive processes and possess a slight antitoxic power against tuberculosis in rabbits. The natural antitoxic power of goat serum may be considerably increased by repeated injections with Koch's new tuberculin. The injection of this serum exercises no effect upon the temperature of the animal. A bibliography relating to serum treatment of tuberculosis is appended to the article.

The control of bovine tuberculosis (*Verslag. Meded. Afdeel. Landb., Dept. Waterst., Hand., Nijv., 1904, No. 3, pp. 30, pls. 2*).—In this pamphlet a general account is given of the present status of bovine tuberculosis in Holland, together with an account of the appearance of the disease in various organs and tissues. Notes are also presented on the losses from this disease, its distribution, and the means which have been adopted for controlling it in Denmark, Norway, Sweden, Belgium, France, and the Netherlands.

Texas fever in the Philippine Islands and the far east. The Australian tick (Boophilus australis) in the Philippine Islands, J. W. JOBLING, P. G. WOOLLEY, and C. S. BANKS (*Philippine Dept. Int., Bureau Govt. Labs. [Pub.], 1904, No. 14, pp. 21, pls. 24, figs. 4*).—In November, 1903, some cattle purchased in California north of the Texas fever quarantine line were landed in Manila and were

treated with immune serum for the purpose of protecting them against rinderpest. Twelve days after the second dose of ordinary prophylactic serum was given virulent blood was obtained and the so-called simultaneous inoculation was given to all except one of the cattle.

Among the cattle treated in this way, all except those which had just been imported from the United States gave reactions which were usually observed after inoculation with rinderpest blood. The results of treatment with the American cattle, however, were disastrous and a number of them died with the symptoms and pathological lesions of Texas fever.

The clinical history of all fatal cases was quite similar. These complications led to a study of the origin of the disease. It was found by inoculation tests that the native and Chinese cattle of the Philippine Islands were not susceptible to inoculation with blood containing the Texas fever organism, and that blood obtained from these cattle produced Texas fever in susceptible American cattle. It appears, therefore, that Texas fever is enzootic in the Philippine Islands and that the majority of the native and Chinese cattle are immune to the disease.

The tick which serves to carry the disease in the Philippines is *Boophilus australis*. Notes are given on the appearance, habits, life history, anatomy, and distribution of this tick. It passes at present under various names, such as the Australian, South American, Cuban, or Porto Rican tick, on account of its being found in all of these countries, and is specifically distinct from the Texas-fever tick of the United States.

Preliminary report on the study of rinderpest of cattle and carabaos in the Philippine Islands, J. W. JOBLING (*Philippine Dept. Int., Bureau Govt. Labs.* [*Pub.*], *1903, No. 4, pp. 22, pl. 1*).—A brief review is presented of the symptoms, means of transmission, pathological anatomy, and treatment of rinderpest. While most authors lay stress upon the frequency with which ulcers are to be found in the mouth in cases of this disease, this statement is found to be contrary to the experience which the author had in the Philippines. Clinical notes are given on a number of cases.

In controlling the disease the author recommends immediate isolation of all affected animals and the application of thorough disinfection. Exposed animals or other healthy animals may be immunized by one of several methods, which have already been described by different authors. These methods are briefly mentioned and attention is called to their chief advantages and disadvantages. The simultaneous method with serum and virulent cultures is perhaps best when it can be conveniently applied. In distant provinces, where it is impossible to obtain help or means of using this method, immunity may be produced by inoculation with defibrinated blood. Little effect can be produced by the use of any known method of treatment for rinderpest.

Veterinary notes. Diseases of sheep, T. W. CAVE (*Jour. Southeast. Agr. Col., Wye, 1904, No. 13, pp. 64–83, figs. 6*).—The author investigated an outbreak of a disease among sheep in which the sheepmen referred to affected sheep as "struck." The disease was found to be blackleg and the blackleg bacillus was found in every case which was investigated bacteriologically. Vaccination experiments were tried with satisfactory results.

It was found that the single vaccine as applied to 200 sheep was perfectly safe, but the duration of immunity thus produced was not determined. The double vaccine proved to be somewhat uncertain in its action and was slightly dangerous under certain circumstances. The danger from the use of vaccine is apparently considerable if vaccinated sheep are exposed to severe weather during the critical period.

A tapeworm disease due to *Moniezia expansa* in lambs was studied by the author and a successful method of control was elaborated. This consisted in accustoming the lambs to eat from troughs as soon as possible after birth. As soon as the lambs eat readily from the troughs a mixture containing linseed cake, pea meal, common

salt, aniseed, and sulphate of iron is added to the dry food already allowed. Apparently the lambs derived great benefit from dry feed combined with a tonic. A brief account is also presented of the flukeworm disease of sheep, with notes on the habits and life history of this worm and the usual methods of preventing infestation by it.

Report of sheep-dipping committee (*Jour. Bd. Agr. [London], 11 (1904), No. 6, pp. 358–364*).—A summary is presented of experiments in dipping sheep during which a large number of substances are employed as dips. The committee did not recommend any special dip as the result of their experiments, but it was found that the best dips of all classes are quite effective against both sheep scab and sheep ticks. It is recommended, however, that wherever a second dipping becomes necessary within 12 days, none of the arsenical or poisonous dips should be used. It was shown conclusively that one dipping with a good dip is enough to cure sheep scab. Carbolic dips as well as arsenical and sulphur dips are thoroughly effective in curing sheep scab, but the experiments showed that the use of the latter dips in too strong solution was attended with some danger to the sheep.

Diseases of swine, R. A. CRAIG and A. W. BITTING (*Indiana Sta. Bul. 100, pp. 71–204, figs. 23*).—This bulletin is in the nature of a brief handbook on the diseases of pigs. It is offered as a summary of investigations regarding the more important diseases which affect this animal.

Attention is called to the great importance of the swine industry and to the large losses which this business suffers through the prevalence of diseases. A general account is presented on the nature of diseases and the common means of spreading infection. Notes are also given on the methods of administering medicines to hogs. The diseases which are discussed in the main part of the bulletin are arranged according to the organs or parts most seriously affected. These diseases include all forms of digestive disturbances, including poisoning from various sources, diseases of the peritoneum, liver, urinary apparatus, generative organs, respiratory apparatus, heart, nervous system, udder, and skin.

Particular attention is given to an account of the infectious diseases of the pigs, especially hog cholera and swine plague. The internal and external parasites of pigs are also mentioned and notes are given on means of destroying them. At the close of the bulletin the authors present an account of immunity and vaccination with especial reference to hog diseases.

Swine erysipelas as the result of inoculation, MEYENBERG and WIETHÜCHTER (*Berlin. Tierärztl. Wchnschr., 1904, No. 38, pp. 638, 639*).—In the experiments of the authors in inoculating for the prevention of swine erysipelas, bad results have sometimes occurred in a high percentage of cases. Notes are given on the conditions under which these unfavorable results take place. In order to avoid such mishaps it is recommended that a veterinary serum institute be established open to membership to all of the veterinarians in the German Empire.

Pyemic cachexia and swine plague, OLT (*Deut. Tierärztl. Wchnschr., 12 (1904), Nos. 37, pp. 365–367; 38, pp. 377–380*).—As a result of the author's study of these diseases it is concluded that *Bacillus pyogenes suis*, discovered by Grips, is a specific, pyogenic organism which may cause local suppuration followed by spontaneous healing or chronic pyemia with fatal results. Pigs of all ages are susceptible to pyemic cachexia and young animals are most susceptible to artificial infection. The organism gains entrance to pigs chiefly through lesions due to operations or accidents.

The disease usually appears in an independent form, but may accompany other infectious diseases. It differs greatly in appearance according to the location of the pathological processes. The latter are observed most extensively in the lymphatic system of the abdomen, pericardium, and pleural cavities. The organism when carried through the blood system may cause suppurative inflammation of various joints and may produce metastases in the lungs. Grips' bacillus may even produce suppurative broncho-pneumonia but never swine plague. The latter disease is caused

by the bacillus of Löffler and Schütz. Notes are given on the differential diagnosis between swine plague and pyemic cachexia.

Hog cholera, R. G. MARCO (*Vet. Españ., Madrid, 47 (1904), No. 1689, pp. 406–408*).—Notes are given on the symptoms, lesions, distribution, and treatment of this disease, with an account of the different forms under which it occurs.

An outbreak of anthrax in horses, J. BOURGÈS (*Bul. Soc. Cent. Méd. Vét., 81 (1904), No. 18, pp. 607–625*).—Brief notes are given on some of the more serious outbreaks of anthrax which have occurred in France in former years. The outbreak described in this paper occurred among a regiment of artillery horses numbering 510. After the first case appeared the disease spread rapidly. A number of sources of infection were suspected, among them being forage and water.

Notes are given on the progress of the disease in a number of cases and also on the symptoms and pathological lesions. Treatment appears to be effective only in chronic cases of comparatively mild type. The most successful means of preventing the disease consist in thorough cleansing and disinfection of premises and isolation or destruction of infected animals and proper sanitation for exposed animals.

The etiology of cerebro-spinal meningitis in horses, A. ZANGHERI (*Clin. Vet., 27 (1904), No. 37, pp. 217–221*).—As a result of the author's study and observations on this disease it is concluded that the cause of the disease is the diplococcus of Fränkel. The disease may appear in epizootic form and is apparently identical with the affection in man which is known under the same name.

Poisoning of horses from eating the plant Ornithogalum thyrsoides, D. HUTCHEON (*Agr. Jour. Cape Good Hope, 25 (1904), No. 1, pp. 48–50*).—This plant was found to cause considerable losses among horses under natural conditions, and feeding experiments also demonstrated that the plant contained a violent poison. It produced acute gastro-enteritis and a very serious disturbance of the nervous system. No opportunity was had for attempting the curative treatment, but the author recommends the administration of a mixture consisting of a pint each of linseed oil and limewater.

Infectious catarrh of the upper respiratory passages, BÄCHSTÄDT (*Ztschr. Veterinärk., 16 (1904), No. 10, pp. 429–432*).—An outbreak of this disease occurred among the horses of one of the army regiments. The chief symptoms were a cough, depression, nasal discharge, and swelling of the laryngeal lymphatic glands. The diseased animal, as a rule, showed no elevation of temperature. The disease itself appeared to be undoubtedly infectious. Notes are given on the differential diagnosis between the disease and bronchial catarrh and contagious coryza. The best treatment consists in a suitably regulated diet, rest, and good ventilation. No satisfactory results were obtained by the use of drugs.

Preliminary report of the appearance in the Philippine Islands of a disease clinically resembling glanders, R. P. STRONG (*Philippine Dept. Int., Bureau Govt. Labs. [Pub.], 1902, No. 1, pp. 12, pls. 4*).—Attention is called to the fact that horses in the Philippine Islands are subject to a disease which may closely resemble glanders. The disease begins as a small nodule in the cutis, frequently near some slight abrasion, and extends gradually, in neglected cases, over various parts of the body, including the mucous membranes of the nose. Metastases may occur in the glands, but not so far as has been observed in the internal organs.

This disease is due to a species of blastomyces which does not grow readily on the ordinary nutrient media used in bacteriological study. The disease is distinct from bursattee, or beef farcy, and yields readily to proper treatment. This should consist in shaving the hair around the nodule when it first appears and cauterizing and thoroughly cleansing the nodule with corrosive sublimate, creolin, formalin, or benzoyl acetyl peroxid.

Practical and pathological horseshoeing, C. W. BRODHEAD (*Pennsylvania Dept. Agr. Rpt. 1903, pp. 412–420*).—Special directions are given for preparing and

setting shoes for the purpose of correcting, so far as possible, certain defects, such as toe cracks, corns, navicular disease, overreaching, and founder.

Alexins antagonistic to the spirillum of septicemia of fowls, C. LEVADITI (*Ann. Inst. Pasteur, 18 (1904), No. 8, pp. 511-526*).—The author inoculated a number of rabbits under the peritoneum with blood containing numerous spirilla from a fowl killed on the third day of infection.

It was found as a result of these experiments that no alexins were developed in the organs or serum of inoculated rabbits at the end of the third day. On the seventh day, however, an extract of the spleen had the power of agglutinating spirilla, and the same was found to be true for extract of the omentum. It was found that between the fifth and seventh days the serum had the power of protecting fowls against the disease after inoculation, although the organs of such rabbits when examined and tested outside of the body showed no bactericidal power. The author believes that the omentum and spleen may be looked upon as special depots for the formation of alexins.

Further experiments along the same line indicate that extracts prepared from blood-forming organs (spleen, bone marrow, lymphatic ganglia) and the omentum show the development of the agglutinating substances inside of 4 or 5 days. The bactericidal power of extracts of these organs in vivo appears not to be developed until after 2 days. The spirilla penetrate into the organs chiefly concerned in the production of immunity by means of the circulatory system.

Notes on the so-called paralysis tick, Ixodes pilosus, C. W. MALLY (*Agr. Jour. Cape Good Hope, 25 (1904), No. 3, pp. 291-296*).—This tick is quite generally considered by farmers to be the cause of paralysis in sheep. A study was made of the distribution, habits, and life history of the tick. From his study of the general conditions surrounding outbreaks of so-called paralysis in sheep, the author concludes that the tick is not in itself the cause of the disease, and that there is no evidence to show that it may convey the disease. Paralysis is checked by proper dipping. One attack of the disease does not lead to complete immunity. Further experiments are necessary in working out the life history of the tick.

Trypanosomiasis of horses in the Philippine Islands, W. E. MUSGRAVE and N. E. WILLIAMSON (*Philippine Dept. Int., Bureau Govt. Labs. [Pub.], 1903, No. 3, pp. 28, pls. 2*).—In this report an account is given of the history of this disease in the Philippine Islands, the method of transmission and infection, symptoms, diagnosis, and means of prevention. Excessive losses have been suffered from this disease in the Philippines. The authors consider trypanosomiasis as one disease, including surra, nagana, tsetse-fly disease, mal de caderas, and dourine. The prevention of the spread of the disease to new centers may be brought about by the thorough application of quarantine laws and the application of proper sanitary methods to infected localities.

Trypanosomiases in French Sudan, L. CAZALBOU (*Rec. Méd. Vét., 81 (1904), No. 19, pp. 615-623*).—Along the Bani River, which is a tributary of the Niger, it has been found absolutely impossible to raise horses, cattle, sheep, goats, or asses. None of these animals are able to live for more than 1 year. An examination of this region showed that a number of flies belonging to the genera Glossina and Tabanus were present, and detailed notes are given on the form of trypanosomiasis in horses. An examination of the blood of affected horses showed that 2 species of trypanosoma were present, one of which appeared to be *T. brucei*, and the other, which was somewhat shorter, but thicker, was unknown. It appears to be a new species and is referred to under the name trypanosoma of baleri, the latter being the name of the disease as observed in French Sudan.

Report of a journey in the region of Kilwa to determine the occurrence and observe the habits of the tsetse fly, V. LOMMEL (*Ber. Land- u. Forstw. Deutsch-Ostafrika, 1 (1903), No. 4, pp. 341-350, fig. 1*).—Notes are given on the distri-

bution of this insect in the province of Kilwa as observed during the author's travels in that region. The tsetse fly appears not to prefer thick brush lands, but occurs in greater numbers in grass lands, especially in the vicinity of a forest. The fly is not particularly associated with a swampy region, but occurs most frequently on higher ground, at considerable distances from swamps. The insect is described in its various stages and notes are given on its life history.

According to the author's observations, there is no remedy which is likely to be effective in destroying this pest. The adult flies may be captured in considerable numbers, and this method of destruction would assist to some extent in controlling the insect. Attention should be devoted chiefly, however, to the prevention and treatment of tsetse-fly disease.

AGRICULTURAL ENGINEERING.

Proceedings of first conference of engineers of the reclamation service, with accompanying papers, F. H. NEWELL (*U. S. Geol. Survey, Water Supply and Irrig. Paper No. 93, pp. 361, fig. 1*).—This conference was held at Ogden, Utah, September 15–18, 1903, in connection with the Eleventh Irrigation Congress.

The bulletin contains, besides minutes of the meeting and a statement of the organization of the hydrographic branch of the U. S. Geological Survey, the address of the chief engineer of the reclamation service and the following papers: Western Hydrology, by N. H. Darton; Forestry and Irrigation, by G. Pinchot; Colonization, by F. de L. B. Tucker; Work of the Reclamation Service, by F. W. Mondell; Investigations in Arizona, by A. P. Davis; Salt River Valley Water Users Association, by B. A. Fowler; Reclamation Work in California, by G. C. Pardee; Work in Colorado, by A. L. Fellows; Topographic Work in the Grand Canyon of the Gunnison, by I. W. McConnell; The Colorado River, by J. B. Lippincott; Conditions in Idaho, by J. L. Morrison; Investigations in Idaho, by D. W. Ross; Limits of an Irrigation Project, by D. W. Ross; Investigations in Montana, by C. C. Babb; Construction in Nevada, by L. H. Taylor; Investigations in Pecos Valley, by W. M. Reed; Examinations in North Dakota, by C. H. Fitch; Irrigation in North Dakota by Pumping, by F. A. Wilder; Conditions in South Dakota, by C. H. Fitch; South Dakota Investigations, by R. F. Walter; Investigations in Oregon, by J. T. Whistler; Investigations in Utah, by G. L. Swendsen; Water Laws of Utah, by F. S. Richards; Work on North Platte River in Wyoming, by J. E. Field; Investigations in Wyoming, by J. Ahern; Work in Washington, by T. A. Noble; Relation of Federal and State Laws to Irrigation, by M. Bien; Electrical Transmission of Power for Pumping, by H. A. Storrs; Correct Design and Stability of High Masonry Dams, by G. Y. Wisner; Reconnaissance and Plans, by G. Y. Wisner, Reports and Statements, by H. N. Savage; Methods and Reports, by J. B. Lippincott; Irrigation Surveys and the Use of the Plane Table, by J. B. Lippincott; The Use of Alkaline Waters for Irrigation, by T. A. Means; Measurement of Flow of Streams, by E. C. Murphy; Instruments and Camp Equipment, by E. M. Douglas; Surveys in Oklahoma, by G. H. Matthes; Colorado River Reclamation Projects, by E. T. Perkins; Reclamation and Water Storage in Nebraska, by O. V. P. Stout; Portland-cement Manufacture, by E. C. Eckel; Legal Status of Irrigation, by H. L. Holgate; Power Development, by H. A. Storrs; The Reclamation Law, and Reclamation Surveys.

Irrigation in Northern Italy, I, E. MEAD (*U. S. Dept. Agr., Office of Experiment Stations Bul. 144, pp. 100, pls. 18, figs. 14*).—This is an account of a study during the summer of 1902 of irrigation methods and practices in Lombardy and Piedmont which was undertaken in accordance with the law requiring this Office to report "upon the use of irrigation waters at home and abroad," and which had for its special object the obtaining of suggestions for the improvement of administrative, engineering, and agricultural practices in the United States.

The report is not a comprehensive treatment of Italian irrigation, but describes only those works and institutions which are thought to contain suggestions of value to American irrigators. The bulletin gives a general description of the Po Valley—water supply, climate, crops, irrigation laws and practice, irrigation works, etc.—and detailed accounts of irrigation under the Naviglio Grande, Villoresi, and Vettabbia canals in Lombardy; and of the water supply, state irrigation works, administration of irrigation works, settlement of water rights, duty and cost of water, structures for measurement and distribution of water, etc., in Piedmont.

This, which is the first part of the report, deals with studies of irrigation in Piedmont and Lombardy west of the canals from the Adda River. A second part will describe the irrigation and drainage works found between the Adda River and the Adriatic Sea, and a third will describe the administration of streams and some of the methods followed by the government in aiding the building of both irrigation and drainage works. A bibliography containing references to 100 of the more important works relating to Italian irrigation is included in the report.

Memoranda of plans of irrigation investigations (*Utah Sta. Circ. 2, pp. 23*).—The instruction and regulations for a series of irrigation investigations carried on in coöperation with this Department, together with memoranda of plans for the work in 1904, are presented. The instructions give in detail the data to be collected, the method of measuring and applying water, and the manner of taking crop and soil samples.

Accuracy of stream measurements, E. C. MURPHY (*U. S. Geol. Survey, Water Supply and Irrig. Paper No. 95, pp. 169, pls. 6, figs. 59*).—"This paper is a revision and enlargement of paper No. 64 [E. S. R., 14, p. 404]. It embodies the results of an extension of the investigations, in the hydraulic laboratory of Cornell University, of the flow of small and moderate sized streams."

Irrigation and land drainage, W. G. COX (*Agr. Gaz. New South Wales, 15 (1904), No. 8, pp. 723–732, fig. 1*).—This is a discussion of the importance of irrigation in New South Wales and of the necessity for drainage in connection with irrigation, as well as of methods and cost of draining swamp lands.

The use of alkaline and saline waters for irrigation, T. H. MEANS (*Forestry and Irrig., 10 (1904), No. 8, pp. 350–354*).—A general discussion of the subject.

Hydrographic manual of the United States Geological Survey, E. MURPHY, J. C. HOYT, and G. B. HOLLISTER (*U. S. Geol. Survey, Water Supply and Irrig. Paper No. 94, pp. 76, pls. 3, figs. 10*).—This bulletin "gives instructions for field and office work relating to gauging of streams by the use of current meters."

Tilling the "tules" of California, A. J. WELLS (*Amer. Mo. Rev. of Reviews, 30 (1904), No. 176, pp. 312–317, figs. 12*).—A general account of the reclamation and culture of the tule lands in the vicinity of the junction of the Sacramento and San Joaquin rivers in California.

How the Dutch have taken Holland, F. D. HILL (*Amer. Mo. Rev. of Reviews, 30 (1904), No. 176, pp. 318–322, figs. 4*).—A general account of the reclamation of land from the sea in Holland and of the proposed drainage of the Zuyder Zee.

Irrigation on the Lower Durance, G. CARLE (*Jour. Agr. Prat., n. ser., 8 (1904), No. 39, pp. 402–406*).—The system followed in this region is briefly described.

Historic highways of America, A. B. HULBERT (*Cleveland, Ohio: Arthur H. Clark Co., 1904, vols. 13, pp. 231, pls. 5, maps 2; 14, pp. 234, pls. 3, maps 2*).—These two volumes deal with the great American canals, the first with the Chesapeake and Ohio Canal and the Pennsylvania Canal and the second with the Erie Canal. (For notes on previous volumes see E. S. R., 16, p. 306.)

MISCELLANEOUS.

Report of work at McNeill Branch Station for 1903, E. B. FERRIS (*Mississippi Sta. Bul. 83, pp. 34*).—A general statement is made regarding the work, stock, and equipment of the branch station. Physical and chemical analyses of the soil at the station are given, as well as analyses of 9 commercial fertilizers used in comparative field tests. The results of experiments with a number of field, garden, and orchard crops, and of feeding experiments with steers are noted elsewhere in this number. The bulletin also contains a summary of the temperature and precipitation during each month of the year.

Fourteenth Annual Report of Utah Station, 1903 (*Utah Sta. Rpt. 1903, pp. XLII*).—An outline is given of the work of the various departments of the station during the year, with a financial statement for the fiscal year ended June 30, 1903, and an index to the annual report and the bulletins published during the year 1902–3. An account of cooperative experiments carried on with this Department for the control of sugar-beet disease is noted elsewhere in this number, as is also an account of some plants supposed to be poisonous to stock, and of work in the control of insects.

Yields of the principal cereals in 1903 (*Stat. Jahrb. K. K. Ackerbau Min., 1903, No. 1, pp. 41–54*).—Statistics on the production of wheat, rye, barley, oats, and corn in Austria for the season of 1903 are given.

Mixed farming at Wagga Experimental Farm, W. H. CLARKE (*Agr. Gaz. New South Wales, 15 (1904), No. 4, pp. 301–312, figs. 9*).—Data are given regarding the feeding of sheep, turkeys, and pigs, raising of horses for farm requirements, and the ensiling of natural grasses, herbage, and cultivated crops.

Memoranda of plans for arid farm investigations (*Utah Sta. Circ. 1, pp. 63, dgms. 6*).—This circular contains the plans for proposed experiments to determine the possibility of growing crops without irrigation. Appropriations for this purpose were made by the State, and the work was placed under the direction of the experiment station. Six farms have been selected in different parts of the State and the work to be done on each one is outlined and indicated upon a plan. General instructions to the foremen and employees of the farm are also given.

Farmer's cyclopedia of agriculture, E. V. WILCOX and C. B. SMITH (*New York: Orange Judd Co., 1904, pp. XXIV + 619, figs. 477*).—A handbook of agriculture, horticulture, animal husbandry, dairying, and the like, written in popular style, and intended as a reference book for farmers and others interested in agricultural practice.

The volume is divided into eight parts, treating respectively of field crops, garden crops, fruits and nuts, cattle and dairying, other live stock, poultry, fertilizers, soils, drainage and irrigation, and miscellaneous matters. The articles under each section are arranged alphabetically on the plan of an encyclopedia, and are short and concise in treatment. While the style is popular, free use has been made of the work of the experiment stations and this Department, and the results have been drawn upon largely in discussing improved methods of agricultural practice. Indeed, the book may be regarded to quite a large extent as a concise summary of the more recent literature of agriculture published by the various agencies for agricultural experiment and investigation in this country.

The scope of the work is quite broad, including the treatment of plant and animal diseases, the methods of combating injurious insects, various classes of agricultural organizations and institutions, agricultural industries of minor importance, periodical and other literature relating to agriculture, and other matters of general interest, as well as questions relating to agricultural management. The large number of illustrations add materially to the value and interest of the volume, and the detailed indexes, arranged under both scientific and common names, enable ready reference to any of the topics treated.

NOTES.

Alabama College Station.—C. F. Kinman has been appointed assistant horticulturist of the station, vice T. B. Rivett, resigned.

California Station.—R. E. Mansell has been appointed head gardener of the central station at Berkeley, in place of Emil Kellner, deceased. The board of regents has appropriated $7,000 for the erection of a temporary building for the entomological division near the present station building, in order to relieve the crowded condition arising from new activities.

Colorado College and Station.—At a recent meeting of the board of trustees it was decided to regard all work in agricultural experimentation at the college as experiment station work, to be carried on under the direction of the station, and to make the appropriations for this work directly to the experiment station. Provisions were made for entering into a contract with this Department in horse breeding experiments. The college this year inaugurated a short course in practical agriculture for mature stockmen and farmers, which began January 16 and continued for two weeks. Special attention was given to the judging of different classes of live stock, and also to their common diseases, feeding, breeding, and management. Good representatives of the various breeds of live stock and of types of the market classes were secured for demonstration, and leading feeders and breeders of the various classes of live stock assisted in the lectures and demonstrations.

Connecticut Storrs Station.—Theodore Issajeff has been appointed cheese maker in the cooperative work between the station and the Dairy Division of this Department.

Louisiana University and Stations.—W. C. Stubbs, who has been since 1885 professor of agriculture in the State University and director of the experiment stations, has voluntarily retired. He is succeeded by Prof. W. R. Dodson, who becomes, by virtue of his office as professor of agriculture at the university, director of the three stations in the State, director of the State geological survey, official chemist, etc.

Massachusetts College.—At the annual meeting of the board of trustees, held early in January, attention was called to the overcrowded condition of the college, which has made it impossible this year to give the instruction called for in the courses to all of the students. To meet this contingency and to provide facilities which the college has long needed it was decided to ask the State legislature for a total appropriation of $106,650, mainly for buildings. This amount includes $40,000 for a horticultural building and equipment, $14,600 for a greenhouse for demonstration work in market gardening, floriculture, etc., and $35,900 for an addition to the botanical building of the experiment station, to be used for instruction purposes, together with equipment for the same. An appropriation of $5,000 is to be asked for improved live stock, and a similar amount for enlarging the electric-light plant. President H. H. Goodell was granted six months' leave of absence, owing to the condition of his health.

Nevada Station.—Oscar J. Smith, of Reno, and Henry S. Starrett, of Battle Mountain, have been elected to the board of control. Mr. Starrett formerly served on the board for a period of six years. The station has recently added to its live stock by the purchase of 2 pure-bred Holstein cows, a pure-bred Holstein bull, 4 grade

Holstein cows and heifers, 30 grade Merino sheep, a pure-bred Berkshire sow, and a pure-bred Duroc Jersey sow.

New York State Station.—S. A. Beach has been elected professor of horticulture in the Iowa College, and horticulturist to the experiment station, and will enter upon his duties next September.

North Carolina Station.—The North Carolina State board of agriculture at its recent meeting established an experiment farm near Hendersonville, in the mountain section of the State, where experiments will be conducted with orchard fruits and trucking crops which are or can be grown to advantage in the mountain section of the State. Work will be begun on this farm early in January.

The location of another farm in the eastern trucking section of the State was authorized for the purpose of conducting experiments with truck crops, the growing of which has become a large and important industry in the eastern section of the State. A site has not yet been selected, but it is hoped to obtain it in time to begin work in the spring. The department already has in operation two farms of the kind referred to above, one being located on a good type of red-clay land in the Piedmont section and the other in the northeastern coastal plain section. Both of these farms are given up to experiments with general farm crops. They have been in operation two and four years, respectively, and have proved quite satisfactory for the purpose for which they were used.

Ohio Station.—F. A. Derthick has resigned his membership in the board of control in order to accept a similar position in the board of trustees of the State University, and T. C. Laylin, of Norwalk, has been appointed in his place.

Oklahoma College and Station.—C. H. Tourgee, B. S. A., a graduate of the Iowa State College, has been appointed assistant in dairying in the college and assistant in agriculture in the station, vice J. B. Griffing, resigned.

Pennsylvania Station.—The last number of *Landwirtschaftliche Jahrbücher*, the official organ of the Prussian ministry of agriculture, contains a translation in full of the report upon the first year's experiments with the respiration calorimeter at the Pennsylvania Station, which recently appeared as Bulletin 51 of the Bureau of Animal Industry. J. P. Gray has been appointed by the United States Secretary of Agriculture as assistant expert in animal nutrition for four months beginning December 20, and assigned for duty in connection with the investigations to be carried on with the respiration calorimeter.

Tennessee Station.—H. A. Morgan, professor of zoology and entomology in the Louisiana State University and entomologist of the experiment station, has been chosen director of the Tennessee Station.

West Virginia Station.—Frank H. Grout has been appointed assistant chemist and will devote his time largely to work for the State geological survey under the direction of the station chemist.

Wyoming College and Station.—When the Wyoming State constitution was adopted in 1890 the several State institutions were temporarily located for a period of ten years. The last State legislature provided that the question of permanent location of State institutions should be submitted to popular vote, and by the recent election the State University has been permanently located at Laramie. The question of separating the agricultural college and experiment station from the university will again come before the legislature this winter, and it is hoped that final disposition of the matter may be made. Because of the high altitude of the experiment station at Laramie, which makes its conditions different from those of any other station, there is a strong sentiment in favor of its present location.

Referees of Official Agricultural Chemists.—The referees appointed for the coming year are announced as follows: *Phosphoric acid*, E. W. Magruder, Richmond, Va.; *nitrogen determination*, F. A. Urner, Geneva, N. Y.; *separation of nitrogenous bodies*, R. Harcourt, Guelph, Canada (milk and cheese proteids); *potash*, G. S. Fraps, Col-

lege Station, Tex.; *soils*, C. G. Hopkins, Urbana, Ill.; *dairy products*, G. E. Patrick, Washington, D. C.; *foods and feeding stuffs*, J. O. La Bach, Lexington, Ky.; *food adulteration*, W. D. Bigelow, Washington, D. C.; *sugar*, L. S. Munson, Washington, D. C.; *tannin*, H. C. Reed, Stamford, Conn.; *insecticides*, B. H. Smith, Washington, D. C.; *inorganic plant constitutents*, R. W. Thatcher, Pullman, Wash.; *medicinal plants and drugs*, L. F. Kebler, Washington, D. C.

Following are the associate referees: *Phosphoric acid*, J. A. Bizzell, Ithaca, N. Y.; *nitrogen determination*, J. H. Gibboney, Blacksburg, Va.; *separation of nitrogenous bodies*—meat proteids, W. International Live Stock Exposition, 1904.—The International Live Stock Exposition was held in Chicago November 26 to December 3, and in all essential features was even more successful than earlier expositions. The exhibits of fat stock, breeding cattle, sheep, swine, and horses were very fine. Owing to the danger to breeding classes of swine from hog cholera, the exhibit this year was confined to fat barrows, which could be marketed at the close of the show, an innovation which seems to have been regarded with much favor by exhibitors. As is generally the case, the agricultural colleges and experiment stations were well represented in the list of judges, officials, exhibitors, and in other ways.

Prof. C. F. Curtiss, of the Iowa Station, one of the directors and a member of the executive committee of the association having the management of the show, was one of the judges, as were also Profs. W. L. Carlyle, J. A. Craig, W. A. Henry, G. C. Humphrey, and W. J. Rutherford, while Drs. G. H. Glover and A. T. Peters were on the veterinary board.

The numerous entries of the colleges and stations resulted in a large number of prizes. In the college competitions special prizes were offered for stock from the agricultural colleges and experiment stations, and there were entries from the Iowa Agricultural College and Station, Minnesota Experiment Station, Purdue University, University of Nebraska, and University of Wisconsin. The Minnesota Station won first prize for 2-year-old steers, Purdue University second, the University of Nebraska third, and the Iowa Agricultural College fourth. For yearlings, the Iowa Agricultural College won first and third prizes, the University of Nebraska second, and Purdue University fourth. For the calves, Iowa Agricultural College won first and third, Purdue University second, and the University of Minnesota fourth prize. Clear Lake Jute No. 2, of the University of Minnesota, was champion, while the Iowa College was given first place for a herd of 3.

In the college sheep classes the University of Wisconsin won first, second, and third prizes for pure-breds, grades, and crossbred wethers a year old and under 2 years. It also took first, second, and third prizes for wether lambs, and a special prize for the best 5 wethers under 2 years old, and showed the champion wether.

In the college swine show the Iowa Agricultural College won first and third prizes, and the Minnesota Experiment Station second, for barrows under 12 months old, while the former institution also received a prize for the best 5 barrows under 2 years old, and the barrow championship.

The colleges and stations also won a number of prizes in the classes open to all competitors. In the fat-stock class the grand championship was for the third consecutive year awarded to a college or station exhibitor, the University of Minnesota winning with the 2-year-old Aberdeen-Angus steer, Clear Lake Jute No. 2, which was last year reserve champion, and was champion over all breeds as a calf. As noted above, he was also champion in the college exhibit. He was bought at auction by the Minnesota Station for about $600, and was fattened at the station, the ration consisting of grain with roots and coarse fodder and pasturage during a part of the time. His weight on December 1, 1903, was 1,620 lbs., and on October 11, 1904, it was 1,790 lbs.

Of the prizes for steers of different breeds and ages, the Iowa College won a first and a fifth prize for Shorthorns, a first for Herefords, and a third for Galloways. The Minnesota Station won a fifth prize for Herefords and Purdue University a fourth for the same breed. In the grades and crosses class, the first prize for 2-year-olds was awarded to the Indiana Station, second to the Nebraska Station, and fifth to the Iowa College. In the senior yearlings class the Nebraska Station won fifth prize. In junior yearlings, the first and second prizes were awarded to the Iowa College. In the junior calf class, the Iowa Station received first and the Minnesota Station second prize.

In the dressed-carcass lots, the second, third, and fourth prizes for 2-year-olds were awarded to the Minnesota Experiment Station and the first prize for yearlings to the Iowa Agricultural College.

For pure-bred fat sheep, the University of Wisconsin received a second prize for Shropshires; a second, third, and fifth for Southdowns; a second for Hampshires, and 2 firsts and 1 second for Cheviots, as well as the championship for a wether of this breed. In the grades and crosses class the same institution received 2 first prizes, 4 seconds, 2 fourths, and 2 fifths, as well as a first prize and the grand championship for a pen of 5 wethers. In this class the Minnesota Station received 2 fourth prizes. The Iowa College received a prize for a carload lot of native wethers 1 to 2 years old.

In the display of fat barrows, the Iowa Station took first, second, and third prizes on Berkshires, as well as all the prizes for which it competed in the Chester White class, and prizes for large Yorkshires, of which it was the only exhibitor. This station was also awarded a grand championship in the Berkshire class of barrows of 300 lbs. or over. This hog was later made grand champion of all breeds, and was shipped back to the Iowa College to serve as a model in class work. The Minnesota Station won a third prize in the Berkshire class, as well as prizes for Tamworths, in which class it was the only exhibitor. The Iowa Station won three second and the Minnesota Station a third prize for pens of 5 barrows in the Berkshire classes. The Iowa College won first and third prizes for dressed carcasses weighing 300 lbs. or over and a second prize for carcasses weighing 200 to 300 lbs.

The University of Illinois did not enter live stock for prizes, but showed a special exhibit of market classes of cattle, which was a collection of carefully chosen animals illustrating all the classes of cattle definitely recognized in the current market quotations. Above each animal was a placard showing its class and giving a description of the type. This exhibit excited much interest.

Large numbers of students from the agricultural colleges were present, and a meeting of the American Federation of Agricultural Students was held on the evening of November 29.

The student stock-judging contest, the fifth annual competition, took place on November 26, and was participated in by the Iowa, Kansas, Michigan, Ontario, and Texas agricultural colleges and by the universities of Minnesota and Ohio. This year the contest was divided into 2 sections, one for cattle, sheep, and hogs, and the other for horses. The Ohio students won the Spoor trophy for the best work in judging cattle, sheep, and swine, the Texas team ranking second. The Spoor trophy for horse judging fell to the Iowa College, the Ontario team ranking next. Cash prizes aggregating $500, offered by one of the Chicago commission firms, were awarded to individual members of the competing teams making the highest score of points, W. A. Martin, of Ohio, receiving first prize and W. C. McKillican, of Ontario, second.

On November 28 a corn-judging contest was held for a fine bronze trophy, offered by A. E. Cook, of Iowa, which was open to all college students. The only institutions participating were the Iowa and Kansas colleges, first place being awarded to the Kansas team. The competitors were given 5 samples of corn each, made up of 10 ears, 3 samples to be judged as pure-bred types and 2 as corn best suited for farmers' needs regardless of types. The competitors were required to select the first, second, and third best ears and give reasons for the selections made.

The annual meeting of the International Live Stock Association was held in the Assembly Hall of the Pedigree Record Building on Monday, November 28, and was largely attended. An address was delivered by Dr. A. B. Storms, president of the Iowa Agricultural College, on the Economics of Modern Industry, special stress being laid on the live-stock exhibit as a factor in education.

The enthusiasm manifested at the meeting and the sums of money pledged indicate that the much-needed colosseum will be built, so that the international live-stock shows may be held in the future under much better surroundings than at present.

Prof. J. L. Budd.—Prof. Joseph L. Budd, of Iowa, who died at Phoenix, Ariz., November 20, was a pioneer in horticultural instruction. He was one of the very first to occupy a chair in that subject after it was given a separate place in the agricultural curriculum, and for 23 years he remained at the head of the horticultural department of the Iowa Agricultural College, retiring in 1898 as professor emeritus.

Previously a successful nurseryman, whose writings had given him wide reputation, he brought to his college position a clear insight into the possibilities of western horticulture, which enabled him to become a leader in establishing fruit growing in a country where the early indications foreshadowed failure. The varieties and methods which had succeeded in the East were found valueless in that country subject to periods of drought in summer and extreme cold in winter. The whole system of fruit growing had to be revolutionized.

Professor Budd was among the first to advocate the value of Russian fruits for the West, and was instrumental in securing the importation of many scions of these fruits between 1875 and 1880. In 1882 he made an extended visit to Russia and Northern Europe, securing for importation numerous varieties of apples, pears, plums, forest trees, ornamental shrubs, etc., which eventually were widely introduced throughout the State and in the Northwest. These importations have infused an element of hardiness into the fruits of that section, and considerably extended the limits of successful fruit culture, besides adding greatly to the arboriculture of the region.

Professor Budd was for 18 years secretary of the Iowa State Horticultural Society, whose reports contained many of his writings; and was joint author with his former pupil, Prof. N. E. Hansen, of the American Horticultural Manual, a comprehensive two-volume work published in 1902–3. He had been in failing health for several years past, and had spent his winters South. His death was due to a general breakdown, from which at his age (nearly 70) he was unable to rally.

Death of Director Wilfarth.—Hermann Wilfarth, director of the agricultural experiment station at Bernburg, Germany, died November 27, 1904. He was for many years assistant to Prof. H. Hellriegel at the Bernburg Station, and was associated with him in the classic investigations on the nitrogen feeding of Gramineæ and Leguminosæ, published in November, 1888, in which the assimilation of the free nitrogen of the air by leguminous plants in symbiosis with root tubercle bacteria was first clearly demonstrated and explained. He was also associated with Hellriegel in the development of his system of sand-culture experiments, and had charge of many of the details of the experiments. Upon the death of Hellriegel, in 1895, he succeeded him as director of the station, and has continued the study of the fertilizer requirements of plants in pot cultures. He was born in Hamburg May 21, 1853.

Prof. Selim Lemström.—The issue of *Nature* for December 8 contains an obituary note upon Prof. Karl Selim Lemström, of Finland, the widely known physicist and meteorologist, whose death occurred October 2. Professor Lemström's name is a familiar one to the readers of this journal, where his work of agricultural interest has been frequently noted. He made an interesting study of night frosts and the means of preventing their devastations by artificial clouds of smoke, for the production of which he devised torches or tubes of peat. His work on this subject was extended by other investigators to several countries. He also made important experiments on the influence of electricity on plant growth, and several of his papers upon that subject have been abstracted in the Record.

Miscellaneous.—A note in *Nature* states that in the sale of Chartley Park, Staffordshire, the remnant of the celebrated herd of white cattle which have been kept on this estate for the last 700 years, did not go with the park, and will consequently come under a separate ownership. Much regret is expressed at this, and it is hoped that they will be given a safe home by their new owner where they will flourish and increase. The herd is believed to be reduced to 9 head, and it is pointed out that the capture of these by the new owner will be no easy task. In commenting upon the herds of wild cattle in various British parks, it is stated that these were long considered to be direct descendants of the wild aurochs, but "it is now generally admitted (largely owing to the writings of Mr. Lydekker) that they are derived from domesticated albino breeds nearly allied to the Pembroke and other black Welsh strains, some of which show a marked tendency to albinism. This view, as pointed out by a writer in the *Times* of November 29, is strongly supported by the fact that the Chartley cattle frequently produce black calves. The theory advocated by a later writer in the same journal that the British park cattle are the descendants of a white sacrificial breed introduced by the Romans rests upon no solid basis."

A yearbook of plant diseases has been established in Russia under the Imperial Botanical Garden. This is based largely on the correspondence which comes to the garden, and the reports of a large number of voluntary observers who send in samples of the diseased material and information concerning the distribution of the disease. The yearbook for 1903, which has been issued, contains descriptions of these diseases, the extent of their ravages, and means of combating them. The work is directly under the charge of the Central Phytopathological Station.

Prof. Willet M. Hays, of the Minnesota College and Station, entered upon his duties as Assistant Secretary of this Department with the beginning of the new year. He has been granted leave of absence by the Minnesota institution.

E. H. Webster, a graduate of the Kansas Agricultural College, and for a time an assistant in dairying in that institution, has been appointed chief of the Dairy Division in this Department. Mr. Webster was formerly connected with the Division as dairy inspector.

Dr. F. Nobbe, professor of botany and plant physiology in the Forest Academy at Tharand, Germany, has retired.

O

EXPERIMENT STATION RECORD.

Vol. XVI. February, 1905. No. 6.

The statistics relating to the students in agriculture at the agricultural colleges of this country permit of some interesting deductions as to the attendance and the teaching force. These statistics have just been compiled by this Office from returns made by the colleges to the Bureau of Education.

Forty-four institutions report a total enrollment of 2,904 students in agriculture and horticulture. This number includes only those taking these subjects in the collegiate course. It does not include the short-course students, who numbered last year over six thousand, or the students in agriculture in the preparatory or high school courses. Michigan reports 148 agricultural students, Illinois 160, Massachusetts 181, Kansas 198, Missouri 200, South Carolina 232, Mississippi 272, and Iowa 357. Twenty-eight colleges report less than fifty students in these subjects, twenty less than twenty-five students, and eleven colleges ten students or under.

The method of classifying the students at various institutions does not make the figures entirely comparable, the requirement at several colleges that all students take agriculture during the first year or two making the apparent number of students in that course relatively large. The grade of instruction at the different institutions also varies considerably. However, these figures are the best obtainable under the circumstances, and are taken as reported by the various institutions.

The numbers of instructors in agriculture and horticulture in the different colleges show, as might be expected, very wide variation. This enumeration has been confined merely to the instructors in the teaching departments of agriculture and horticulture (not the college of agriculture), and includes the teachers in such branches as agronomy, animal industry, dairying, soils, and forestry. Instructors in agricultual chemistry, agricultural botany, and other sciences related to agriculture are not included in this statement, nor are the emeritus professors, the idea being to get at the provision made in the various institutions for the teaching of the agricultural and horticultural branches themselves.

This summary shows that there are at present 268 instructors who may be credited to those departments, an average of 5.7 officers to an institution. But in thirty-one colleges the number is below this average, and in only sixteen is it equal to or above it. As a matter of fact, the average would be materially lower were it not for some six or eight institutions which have a sufficiently large number of instructors to place them in a class by themselves. Several colleges have only a single instructor for these subjects, and often he has teaching work in other branches or duties in the experiment station. More than half of the colleges have from three to five men in these two departments, while eight institutions have from eight to twelve men. Cornell University lists fifteen instructors in these departments, Iowa twenty, and Illinois twenty-one, while Wisconsin heads the list with twenty-three, although several of this number are obviously employed for the short-course work.

These numbers include not only the professors in the branches of agriculture and horticulture, but the assistants and instructors as well. Considering the number of men which the leading colleges now regard as necessary to represent the more general divisions of the subject, it will be seen that a relatively small number of colleges have what can be regarded as a strong agricultural faculty, or have made great progress in diversifying the subject in the direction of providing assistant professors or instructors in its various branches.

A study of the relation between the teaching force in agriculture and horticulture and the number of students in these subjects brings out some interesting points, both in relation to the different agricultural colleges and to other departments of these and similar institutions.

Excluding three colleges for which the returns are incomplete, the general average the country over is a little over ten students to an instructor in agriculture and horticulture. But the variation is very wide. At several institutions there are only two or three students for each instructor in those subjects, while in Illinois there are eight, in Michigan thirteen, in Iowa eighteen, in Oregon and Texas twenty, in Missouri twenty-two, in Massachusetts thirty-six, in South Carolina forty-six, and in Mississippi sixty-eight agricultural students for each instructor. At eighteen colleges there are ten or more students to each instructor in these branches.

Taking all departments of the colleges of agriculture and mechanic arts, and considering all courses except the short and preparatory courses, there is an average of almost exactly ten students to each officer of the college, or the same number as given above for the departments of agriculture and horticulture. The proportion at the Massachusetts Institute of Technology, which embraces the mechanic

arts without the agriculture, is eight students to each instructor, taking the whole institution.

An article in a recent issue of *Science* gives returns for twenty-one of the leading American universities showing the number of students and instructors, and the relative proportion between them in each case. The range of the latter is from one instructor to 4.74 students (Johns Hopkins) to 1:17.45 (Missouri University) and 1:18.63 (Minnesota University). The average for the twenty-one institutions is one instructor to ten students, which, curiously enough, agrees with the relation of students to instructors in agriculture and horticulture.

Several of the universities mentioned have colleges of agriculture connected with them, and in every such case but one the relation of students to instructors is larger in the university than in agriculture and horticulture. Missouri is the exception, with 17.45 students to each instructor for the whole university, and twenty-two to one in agriculture and horticulture. For the University of Illinois the proportion is one instructor to 8.85 students, and in agriculture and horticulture one to eight.

The above relationships are given as illustrating conditions which exist, and not as a statement of the needs of the instruction force in agriculture. The number of students to be taught at any given time is not regarded as the proper basis for determining the strength of the teaching force, if the subject of agriculture is to be properly developed in the institution; but it has so frequently been the basis of contention on the part of college officers that it is interesting to see how it has actually worked out.

The average derived above of one instructor to ten students, representing as it does all departments of the twenty-one universities cited and the colleges of agriculture and mechanic arts as a whole, may fairly be applied to any single department or group of departments. Hence it may be used, as it was above, as a basis of comparison in the case of the departments of agriculture and horticulture, considering these two together; for surely no one will contend that a smaller instruction force in proportion to the students to be taught is needed in those departments than in others where less laboratory and practicum work are involved.

At eighteen agricultural colleges the number of instructors in agriculture and horticulture is less than one instructor to ten students, i. e., the instruction force is below the above average. In fifteen of these cases there are five or less instructors in the departments of agriculture and horticulture, the average for these fifteen being 3.8 instructors. In all of these institutions several of the instructors are also carrying important departments in the experiment station, the directorship often being included. Evidently in these cases insuffi-

cient provision has been made for teaching the subject, in comparison with other departments, although there has been demand for agricultural instruction. Here the contention does not hold that the teaching force is small because of a small demand.

At eighteen institutions, on the other hand, there are only five or less students to each instructor in agriculture and horticulture. This apparently favorable condition is not always an indication that the subject has been developed, for in nine cases this proportion is found to be accompanied by both a small teaching force and a small number of students (ten or less). In other words, there has been little provision and little resulting demand. In one or two cases the disproportion may be ascribed to a considerable increase in the teaching force during the past year or two, from which there has hardly been time to realize a proportionate increase in attendance.

While, therefore, there are difficulties in making comparisons of this sort, it appears evident that a considerable number of institutions located in agricultural communities have not yet made adequate provision in the teaching force for agriculture and horticulture. On the one hand the number of students to the teaching force is disproportionately large at many institutions, due to the fact that the teaching force has not developed in proportion to the demands for instruction. On the other hand there are a considerable number of institutions where the teaching force has remained very low and the attendance likewise.
